FOREWORD

This manual is divided into five volumes: 1 – Chassis, 2 – Engine, 3 – and 4 – Electrical and Body, 5 – Maintenance and Lubrication. These volumes should provide Service Technicians with complete information covering normal service repairs on all 1973 model trucks built by the Ford Companies in the U. S. and Canada. As changes in the product occur, this information will be updated by Technical Service Bulletins. When issued, T.S.B. information always supersedes the information in the manual.

Information in each volume is grouped by system or component plus "General Service" part which contains information common to several similar components.

The table of contents on the first page of each volume indicates the general content of the book and provides a handy tab locator to make it easy to find the first page of each "Group." That page will contain an index to "Parts" and the first page of each "Part" contains a detailed index which gives page location for each service operation covered. Page numbers are consecutive in each "Part."

To make reference easier, information has been broken down into smaller units so that essentially there is now one "Part" for each component or system. Group numbers indicate the volume in which the group may be found.

Example: 11 – 02 – 21

Volume 1 – Group 11 – Part 02 – Page 21

The descriptions and specifications in this manual were in effect at the time this manual was approved for printing. Ford Marketing Corporation reserves the right to discontinue models at any time, or change specifications or design, without notice and without incurring obligation.

Identification Codes

GROUP 10

GENERAL INFORMATION

VEHICLE CERTIFICATION LABEL

The Vehicle Certification Label (V.C. Label) is attached to the rear face of the driver's door. The upper half of the label contains the name of the manufacturer, the month and year of manufacture and the certification statement. The V.C. Label also contains the Vehicle Identification Number.

The remaining information codes on the V.C. Label are the same as the Truck Rating Plate Codes (Fig. 1). Vehicle codes shown on the Truck Rating Plate are explained in the following paragraphs.

RATING PLATE

Figure 1 illustrates a typical Truck Rating Plate. On light and medium cowl and windshield vehicles, the Rating Plate is mounted on the right side of the cowl top panel under the hood. On stripped Parcel Delivery vehicles, the rating plate is placed in an envelope and included in the Boxed Items parts. On Bronco models, the plate is mounted on the inside panel of the glove compartment door. On all other vehicles, the Rating Plate is mounted on the rear face of the left front door.

VEHICLE IDENTIFICATION NUMBER

The identification number is the first line of numbers and letters appearing on the Rating Plate (Fig. 1). The first letter and two numbers indicate the truck model and series (the letter prefix identifies the type of body or cab and the numbers are the first two numbers of a truck series). The letter following the truck series code designates the engine identification code. The letter following the engine identification code indicates the assembly plant at which the vehicle was built. The remaining numbers indicate the consecutive unit number. The charts that follow list the various vehicle identification number codes.

VEHICLE DATA

The Vehicle Data appears on the Rating Plate on the two lines following the identification number. The first three digits under W.B. designate the wheelbase in inches. The one or two letters under COLOR identify the exterior paint color (two letters designate a two-tone). The letter and three digits under MODEL designate the truck model within a series. The letter and numerals under BODY designate the interior trim and body type (the letter identifies the interior trim scheme and the numerals identify the body or cab type). The transmission installed in the vehicle is identified under TRANS by either a numeric or alphabetical code (if two symbols appear, the first identifies the auxiliary transmission, if so equipped, and the second symbol identifies the main transmission). A letter and a number or two numbers under AXLE identify the rear axle ratio (when required, a letter is

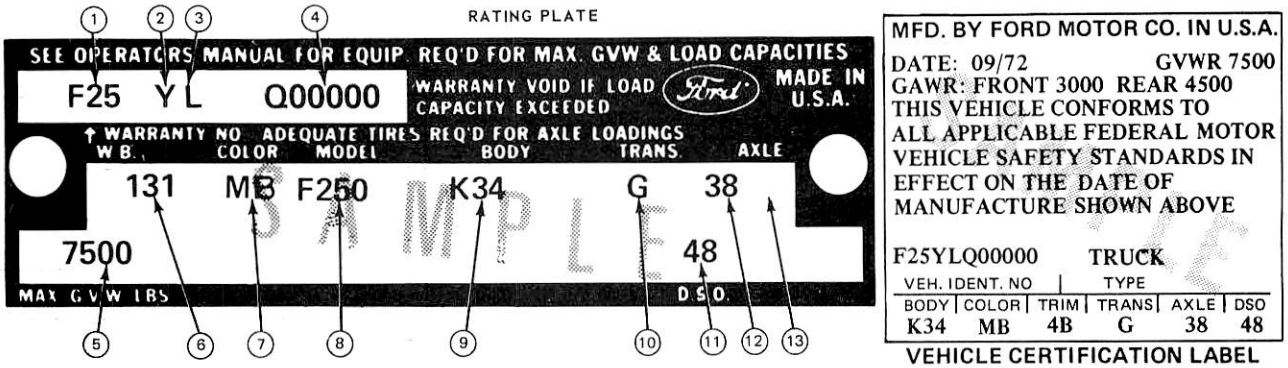

FIG. 1 Typical Truck Rating Plate and Vehicle Certification Label

also stamped behind the rear axle code to identify the front axle capacity). The maximum gross vehicle weight in pounds is stamped under MAX. G.V.W.

A two-digit number is stamped under D.S.O. to identify the district which ordered the vehicle. If the vehicle is built to special order (Domestic Special Order, Foreign Special Order, Limited Production Option, or other special order), the complete order number will also appear under D.S.O. The charts that follow list the various vehicle data codes.

W.B. (WHEELBASE)

The wheelbase in inches is entered in this space.

MAX. G.V.W. LBS

The maximum gross vehicle weight in pounds is recorded in this space.

D.S.O.

If vehicle is built on a **D.S.O., F.S.O., L.P.O.** (special orders) the complete order number will be reflected under the D.S.O. space including the District Code Number.

SAFETY

SAFETY PRECAUTIONS WHEN SERVICING TRUCK TIRES

CAUTION AND SAFETY FIRST are bywords when handling tires, **particularly truck tires!** Careful attention to the suggestions that follow may prevent crippling injuries, or even death. **Make it a rule to respect the terrific force contained in an inflated tire.** You may be glad some day that you did.

Prepare for any tire repair operation in a safe and efficient way. In changing tires on drop center wheels, remove the wheel and tire from the truck. Greater safety, ease and a quicker job can be done than with making the tire change with the wheel on the truck. In servicing of **all tires** use caution not to drop them (or the wheels or assemblies) on the feet, hands or body, or heavily on the floor (Fig. 1). Practice good methods of lifting; use your legs as well as your arms and your body. This can help to prevent painful, internal injury. When carrying tires or wheels don't step in any oil. **Keep the floor clean and dry.**

Deflating a tire properly is very important to your safety. First reduce the pressure **as much as you possibly can** by pushing the valve core plunger. **Only then should you remove the valve core.** Keep your eyes away from the valve! Figure 2 shows the safe way to do it.

Demounting tires from wheels or rims requires special care. Tires on drop center rims are best handled on a wheel holder, or tire changing machine (Fig. 3).

This will prevent cuts on hands and wrists and will make it unnecessary to use a mallet for seating the tire.

Use only standard tire mounting tools and equipment. The use of makeshift tools, screwdrivers or pliers to force tires on or off rims or wheels is **dangerous.**

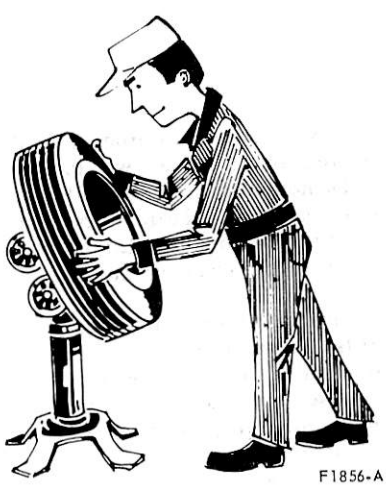
FIG. 5 Tire Spreader

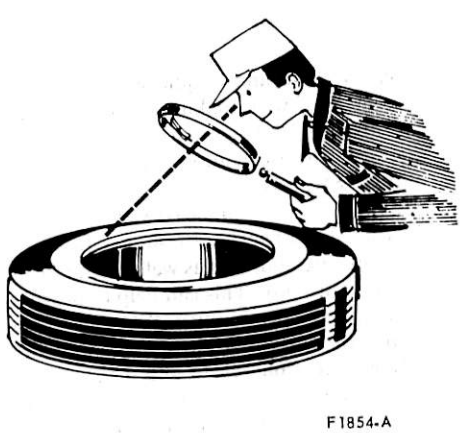
F1855-A

FIG. 8 Inflation Details



F1856-A

FIG. 3 Changing Tire on Drop Center Rim



F1854-A

FIG. 6 Visual Inspection

A new Rotunda tire changer is available. Details include a bead seater/inflator using an automatically adjustable inflation ring. This feature aids in properly seating the bead for inflation. To properly operate the new Rotunda tire changer follow the instructions provided.

As with the drop center rims be certain on split rim assemblies that all air is out before unlocking a rim or ring. Use special care when using tire irons. Grip them firmly and keep them free of oil and grease. They can slip and fly with tremendous force (Fig. 4).

A careful inspection should be made of the tire and all necessary repairs should be performed. A tire spreader is very helpful (Fig. 5) but use care when working around it. Keep the spreader arms closed when the machine is idle.

Inspect the rim parts carefully for rust; damage or distortion (Fig. 6). Never use rims, locking rings or flanges which are out of shape, rusted or cracked or broken in any way. Never use a ring or other rim parts of different manufacture than the original rims or any different size, or type.

Tires and rims often require a buffing operation before being mounted once the regular repairs have been made.

Always wear Safety Goggles, or a face shield when performing any buffing operation.

Avoid hammering rings or rims with steel hammers. Small bits of steel may be broken off the hammer or rim, flying into the eyes (wear safety goggles) face or body. Use rubber-covered, steel-headed hammers wherever possible (Fig. 7). Rubber mallets only should be used on passenger car tires; although with modern tire changing equipment no pounding is necessary.

Make certain the rim ring is seated to full depth of the groove, fits tightly all around, and is securely locked.

Stand away from the valve stem as far as possible while inflating tires. Avoid a position where the face or body is immediately over the work being done on any tire in which there is pressure.

Use only accurate, tested gauges to insure proper air pressure. Check all gauges regularly with a master gauge.

Play it SAFE. Set a good example for others who work with you. Follow the above suggestions completely. If you are ever tempted to take a short cut because you are in a hurry, that is the time that **you could get hurt!**

With certain types of wheels, however, it is necessary to seat the rings while the tire is being inflated. In either case **before inflating study the next step.**

Attach a portable safety device, made especially for the purpose, to the assembly. This portable device should be used with all types of wheels and rims.

Or, if the assembly is not of the type which requires inflation to seat the rings, a **Safety Cage** should be used, although the portable device is the best (Fig. 8).

ADJUSTMENTS

WHEEL BALANCING

See the instructions provided with the Rotunda Wheel Balancer.

Make certain that the brakes are not dragging before attempting to spin the wheels. On vehicles equipped with disc brakes, push the brake shoes into the caliper to free the rotor.

FRONT WHEEL BEARING MAINTENANCE

Wheel bearings are adjustable to correct for bearing and spindle shoulder wear. Satisfactory operation and long life of bearings depend on proper adjustment and correct lubrication. **If bearings are adjusted too tightly, they will overheat and wear rapidly. An adjustment that is excessively loose will cause pounding and contribute to uneven tire wear, steering difficulties and inefficient brakes. The bearing adjustment should be checked at regular inspection intervals.**

CLEANING AND INSPECTION

WHEELS

Wheel stud nuts should be inspected and tightened in the first 500 miles, to avoid accidental loosening of the wheels. Loose wheel stud nuts may cause shimmy and vibration. Elongated stud holes in the wheels may also result from the loose stud nuts.

Keep the wheels and hubs clean. Stones or lumps of mud wedged between the wheel and drum will unbalance a wheel and tire.

Check for damage that would affect the runout of the wheels. Wobble or shimmy caused by a damaged wheel will eventually damage the wheel bearings. Inspect the wheel rims for dents that could permit air to leak from the tires.

TIRES

The tires should be checked frequently to be sure that the air pressures agree with those specified for the tires and vehicle model. Inspect the tire threads, and remove all stones, nails, glass or other objects that may be wedged in the thread. Check for holes or cuts that may permit air leakage from the tire, and make the necessary repairs.

Inspect the tire side walls for cuts, bruises, and other damage. If internal damage is suspected, demount the tire from the wheel for further inspection and repair or replacement.

Check the tire valve for air leaks, and replace the valve if necessary. Replace any missing valve caps.

On F-100, 250, 350 and Econoline models, it is important that except for deep dish (dual type) all be balanced.

Fig. 9 describes common tire wear conditions.

FRONT WHEEL BEARINGS

Wheel bearings are adjustable to correct for bearing and spindle shoulder wear. Satisfactory operation and long life of bearings depend on proper adjustment and correct lubrication **If**

bearings are adjusted too tightly, they will overheat and wear rapidly. An adjustment that is excessively loose will cause pounding and contribute to uneven tire wear, steering difficulties and inefficient brakes. The bearing adjustment should be checked at regular inspection intervals.

Front hubs and bearings should be cleaned, inspected and lubricated whenever the hubs are removed or at the mileage/time periods indicated in the maintenance schedule.

New hub grease seals should be installed when the hub is removed. An imperfect seal may permit bearing lubricant to reach the brake linings resulting in faulty brake operation and necessitating premature cleaning or replacement of linings.

Bearing adjustment is described in Part 11-10 for front wheels. Part 11-12 covers front drive bearing adjustment. Part 11-11, and 11-14 cover rear wheel bearing adjustments.

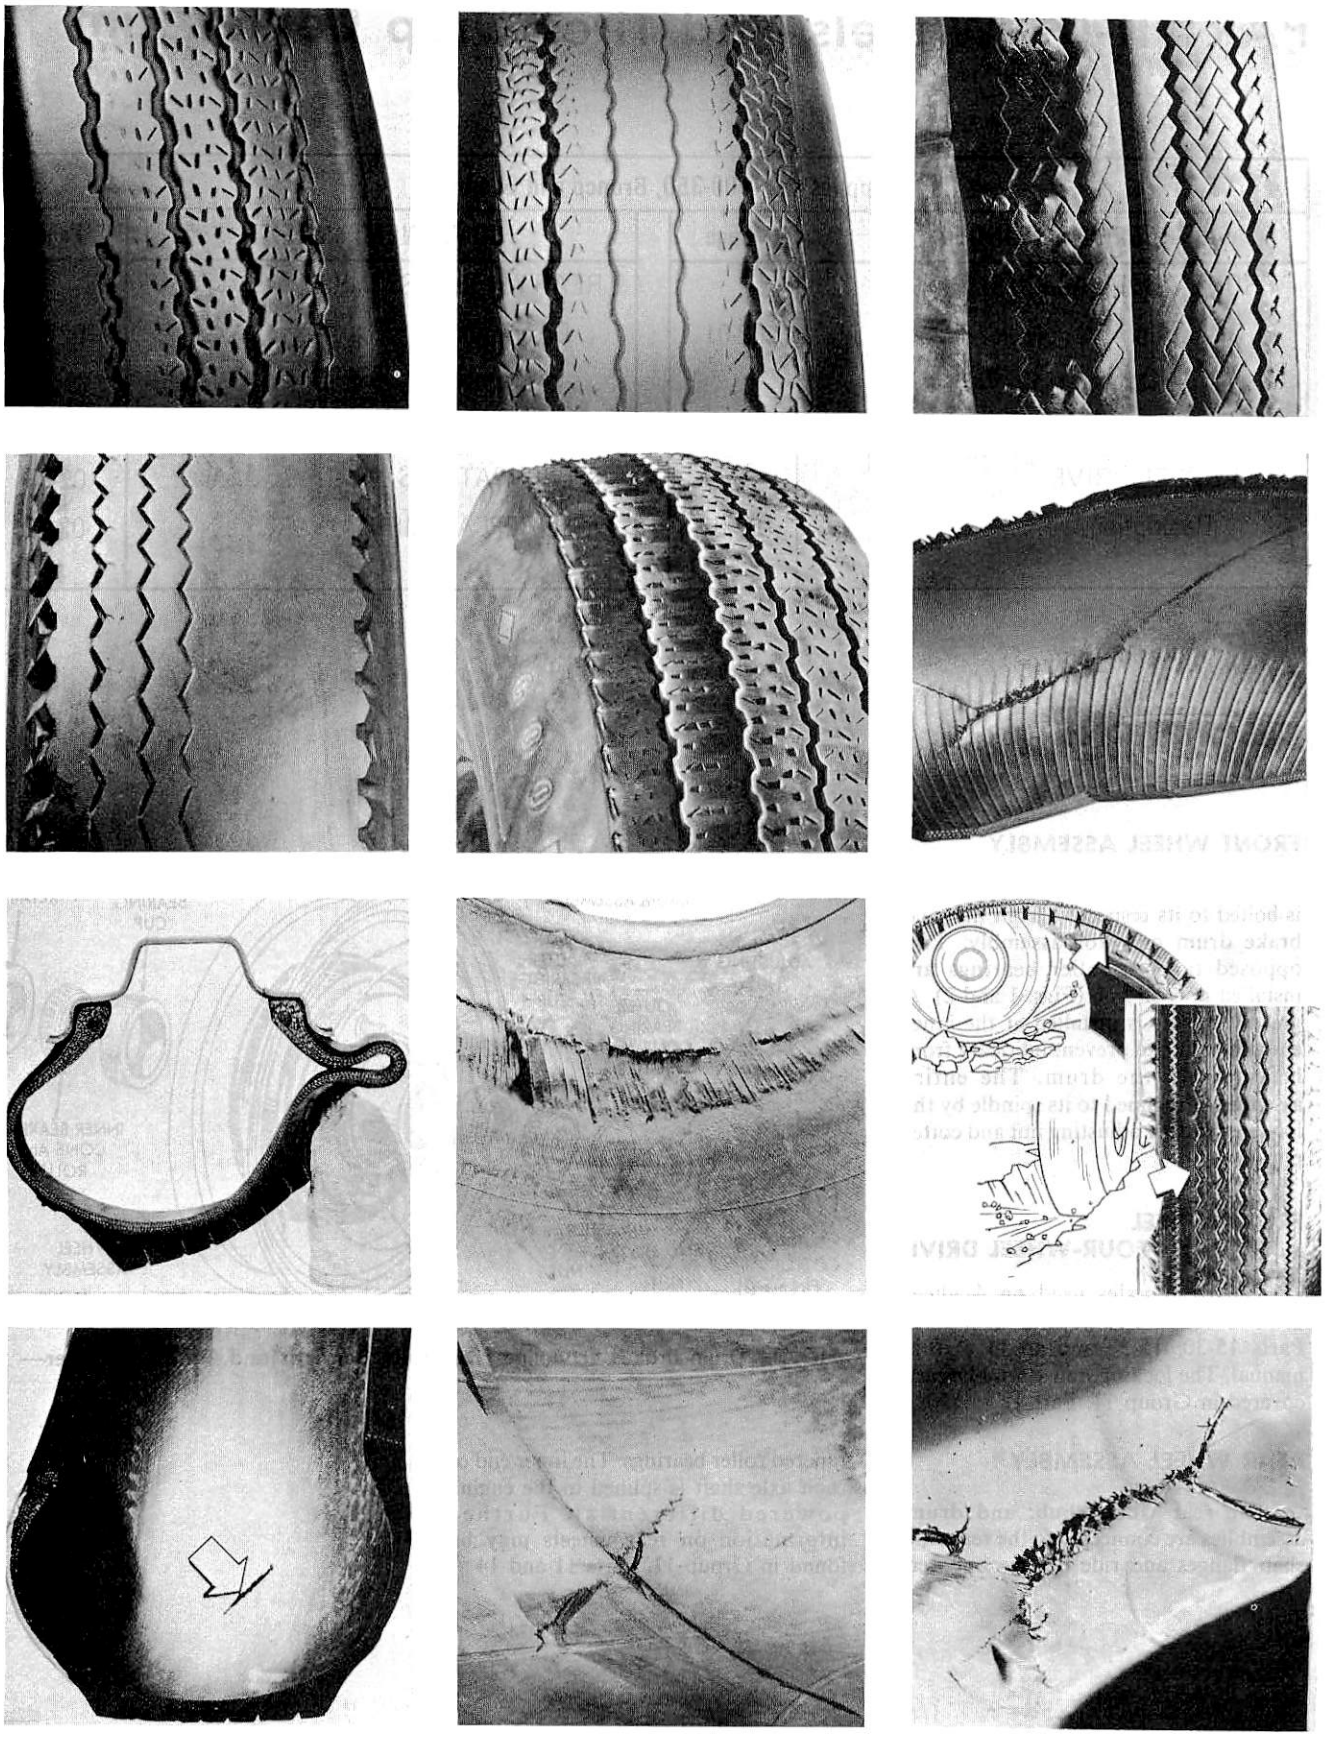


FIG. 9 Tire Wear Conditions

PART 11-02 Wheels and Tires Drop Center Rim

Applies to F-100-350, Bronco and Econoline

COMPONENT INDEX	Page	COMPONENT INDEX	Page
FRONT WHEEL ASSEMBLY		REAR WHEEL ASSEMBLY	
Description	02-01	Description	02-01
FRONT WHEEL ASSEMBLY		WHEEL REPLACEMENT	02-02
4-WHEEL DRIVE		SPECIFICATIONS	02-03
Description	02-01	TIRE REPLACEMENT	02-02

DESCRIPTION

FRONT WHEEL ASSEMBLY

Each front wheel and tire assembly is bolted to its respective front hub and brake drum or rotor assembly. Two opposed tapered roller bearings are installed in each hub (Figs. 1 and 2). A grease retainer is installed at the inner end of the hub to prevent lubricant from leaking into the drum. The entire assembly is retained to its spindle by the lock nut and/or adjusting nut and cotter pin.

FRONT WHEEL ASSEMBLY—FOUR-WHEEL DRIVE

The front axles used on 4-wheel drive models are covered in Group 15, Parts 15-30, 15-32 and 15-33 of this manual. The locking hub assemblies are covered in Group 11, Part 12.

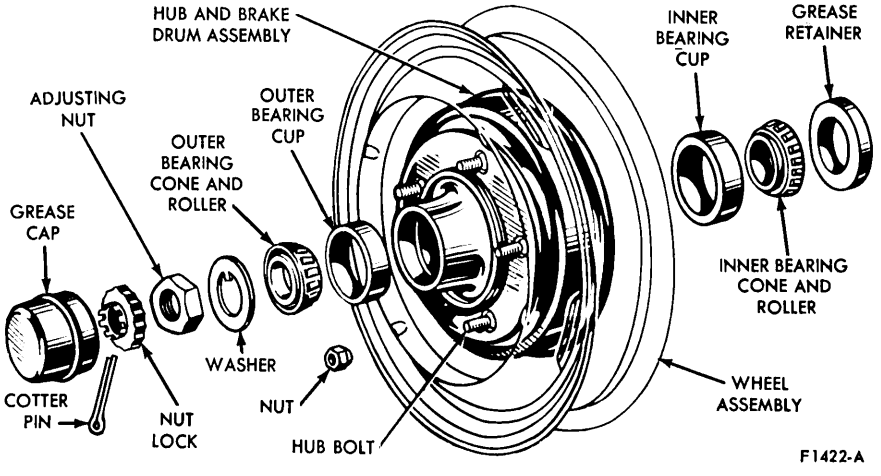

FIG. 1 Drum Brakes Econoline Front Hub, Bearings and Grease Retainer—

REAR WHEEL ASSEMBLY

The rear wheel, hub, and drum assemblies are connected to the rear axle shaft flanges and ride on two opposed tapered roller bearings. The inner end of each axle shaft is splined to the engine powered differential. Further information on rear wheels may be found in Group 11, Parts 11 and 14

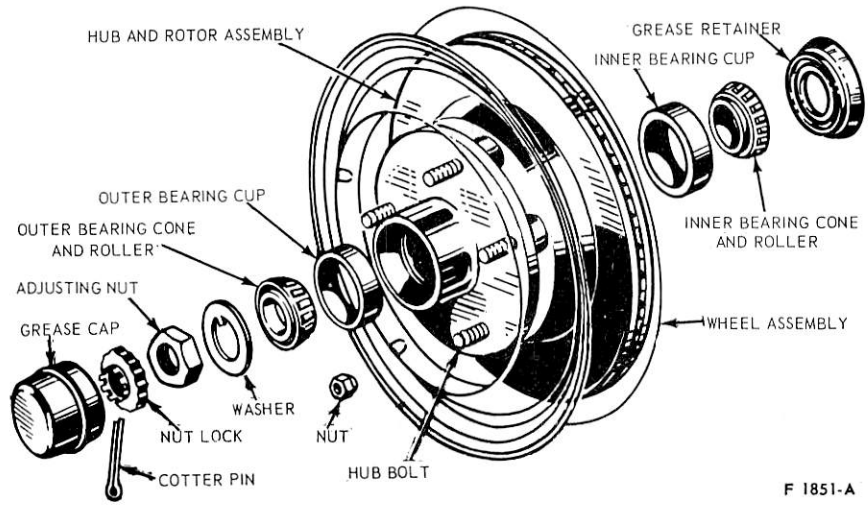

FIG. 2 Front Hub, Bearings and Grease Retainer—Disc Brakes—Typical

REMOVAL AND INSTALLATION

WHEEL REPLACEMENT

LIGHT VEHICLES

Removal

1 Pry off the hub cap (if the vehicle is so equipped), and loosen but do not remove the wheel stud nuts.
2. Raise the truck until the wheel and tire clear the floor.
3. Remove the wheel stud nuts and the wheel and tire from the hub and drum assembly, or the hub and rotor assembly.

Installation

1. Clean all dirt from the hub and drum. The replacement wheel and tire must be clean.
2. Position the wheel and tire on the hub and drum assembly, or the hub and rotor assembly and install the wheel stud nuts. Tighten the stud nuts enough to hold the wheel firmly in place. **Always tighten alternate nuts to draw the wheel evenly against the hub and drum.**

On dual wheels, except F-350, P-350 and P-400 be sure to back off the outer nut before tightening the inner nut. Then tighten the outer nut. F-350, P-350 and P-400 dual wheels have mounting bolt holes which are alternately flared inward and outward. These surfaces must be mated when the sheels are mounted. Fig. 3 illustrates the dual wheel radial alignment locating pin used on certain applications.

3. Lower the vehicle to the floor, and tighten the wheel stud nuts to the specified torque. **On a new vehicle, and each time a wheel and tire is installed, the wheel nuts should be checked for tightness.** When installing the hub cap, notice the wheel hubs. The hub cap should be positioned on the wheel over one of the retaining hubs and the two locating hubs. Be sure that the lip of the hub cap is firmly seated in the groove of the retaining hub, and then force the cap over the second retaining hub. **Any other procedure necessitates heavy pounding with possible damage to the hub cap.**

MEDIUM VEHICLES

Removal

1. Loosen but do not remove the wheel stud nuts.
2. Raise the vehicle until the wheel and tire clear the floor.
3. Remove the wheel stud nuts and the wheel and tire from the hub and drum.

Installation

1. Clean all dirt from the hub and drum. The replacement wheel and tire must be clean.
2. Position the wheel and tire on the hub and drum, and install the wheel stud nuts. Tighten the stud nuts enough to hold the wheel firmly in place. **Always tighten alternate nuts to draw the wheel evenly against the hub and drum.**

On dual wheels, be sure to back off the outer nut before tightening the inner nut. Then tighten the outer nut.

3. Lower the truck to the floor, and tighten the wheel stud nuts to the specified torque. **On new vehicles, and each time a wheel and tire is installed, the wheel nuts should be checked for tightness.**

TIRE REPLACEMENT PRECAUTIONS

The tire must be completely deflated before removal, and the bead must not be damaged by a tire iron.

After installation, a tube tire should be inflated to recommended pressure, deflated, and then inflated again to insure that the tube is not folded inside the tire. Be sure the tube flap is properly positioned before inflating the tire. **On F-100 and 250 series, it is important that each front and rear tire and wheel be balanced.**

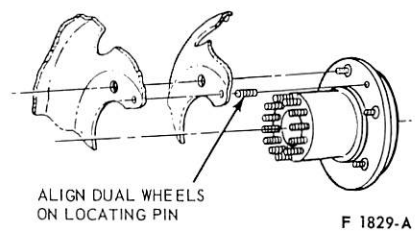

FIG. 3 Dual Wheel Radial Alignment to Hub (F-350)

On E-100 and E-300 all wheels should be balanced. On U-100, and vehicles with dual rear wheels, only front wheels should be balanced.

When installing tires on vehicles equipped with Bead Ledge rims, thoroughly lubricate the tire beads. Inflate the tire until thebead seats against the rim of the wheel, then deflate to the specified pressure. Follow the instructions supplied with the Rotunda (KKRE-888 or equivalent) tire changer.

PART 11-03 Wheels and Tires—Two Piece Rims

Applies to All 500-9000 Series Vehicles				
COMPONENT INDEX	Page		COMPONENT INDEX	Page
TIRE REMOVAL AND MOUNTING – Two-Piece Rims	03-01		TIRE REMOVAL AND MOUNTING – Two-Piece Semi-Drop Center Rims	03-02

DESCRIPTION

Two-piece rims, for disc wheels are used with tube-type tires only. These rims have a 5 degree tapered seat and are available in 5.0, 5.50 and 6.5 rim sizes. **Refer to the first page of Group 11, Part 01 for safety procedures and illustrations.**

REMOVAL AND INSTALLATION

The tire must be completely deflated before removal, and the bead must not be damaged by a tire iron.

After installation, a tube tire should be inflated to recommended pressure, deflated, and then inflated again to insure that the tube is not folded inside the tire. Be sure the tube flap is properly positioned before inflating the tire.

TIRE REMOVAL AND MOUNTING—TWO PIECE RIM

REMOVING TIRE FROM WHEEL

To remove the rim ring (Fig. 1) from a rim without a tire, stand the wheel up so that the tool slot of the ring is at the top, and the lower portion of the ring is in the rim well. Insert the rim tool between the rim slot and the gutter of the rim, lift the ring over the gutter, and pry the ring off the rim (Fig. 2).

1. Place the wheel (ring side up) on the floor. Insert the hook end of the rim tool between the ring flange and the tire bead, and continuing around the ring, pry the tire off the tapered seat of the ring (Fig. 2).
2. Press the side of the ring opposite the double embossing down into the ring well. Insert the straight end of the rim tool into the notch between and below the double embossing (Fig. 4).
3. Force the tool downward to disengage the ring from the rim gutter. **Work the tool around the rim, freeing the ring from the rim, and remove the ring.**
4. Turn the wheel over and loosen the opposite tire bead from the rim by hammering the hook end of the rim tool between the rim flange and the tire bead. Pry the tire bead away from the taper, and remove the tire from the rim (Fig. 3).

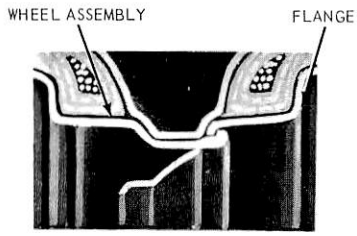

FIG. 1 Two-Piece Rim Installation

Mounting Tire to Wheel

1. After positioning the tube in the tire, place the wheel gutter (Fig. 4). Hook the section soap both beads of the tire and position the tire on the rim.
2. After positioning the tube in the tire, place the wheel gutter (Fig. 4). Hook the section opposite the notch under the gutter so that the cutaway portions of the ring retaining bead span the rim gutter (Fig. 4).
3. Insert the straight end of the rim tool in the notch, and pull the ring onto the rim, at the same time forcing the ring over the gutter with a soft hammer (Fig. 5). Remove the tool, and continue to drive the ring down until it is entirely engaged in the gutter. **Press down on the ring (as shown in Fig. 5) to make certain that it will rock. If there is no movement, the ring is not completely seated and will be forced off violently, either during inflation**

F1338-B

FIG. 8 Removing Split Ring

or when the truck is operated. When inflating the tire, do not stand in front of the ring.

TIRE REMOVAL AND MOUNTING—TWO-PIECE SEMI-DROP CENTER RIM WITH C-STYLE RING

This two-piece wheel uses a split C-type ring (Fig. 6).

REMOVAL OF SIDE RING FROM RIM WITHOUT TIRE

1. Stand the wheel up so that the tool slot of the ring is at the top and the lower portion of the ring is in the rim well.
2. Insert the rim tool between the rim slot and the gutter of the rim. Lift the ring over the gutter, and pry the ring off the rim.

REMOVAL OF SIDE RING FROM RIM WITH TIRE

1. Deflate tire completely and place the wheel (ring side up) on the floor.
2. Break the tire bead free from the rim, being careful not to damage the bead (Fig. 7).
3. Insert the straight end of the rim tool into and under the notch in the ring (Fig. 8).
4. Force the tool downward to disengage the ring from the rim gutter. Work the tool around the rim, freeing the ring from the rim, and remove the ring.
5. Turn the wheel over and loosen the opposite tire bead from the rim by hammering the hook end of the rim tool between the rim flange and the tire bead. Pry the tire bead away from the taper, and remove the tire from the rim (Fig. 9).

MOUNTING TIRE TO WHEEL

1. Position the tube in the tire and place the wheel (gutter side up) on the floor. Soap both beads of the tire and position the tire on the rim. It is important that the tire be soaped well as it must be forced over the safety bead hump and the rim edge (Fig. 10).
2. Position the ring with the notch about 3 inches from the valve stem.
3. Insert the rim tool under the ring at a position approximately 180 degrees from the notch and pry onto rim. Work the remaining section of rim over the gutter with a second tool.
4. Make certain that the ring is entirely seated in the gutter. If the ring is not seated correctly as described, it may be forced off violently, either during inflation or when the truck is operated.
5. After installation, the tire should be over-inflated to 75 psi to snap the tire beads over the bead humps and fully seat the tire against the rim and side ring. Then the tire should be deflated, and then inflated again to recommended pressure to insure that the tube is not folded inside the tire. Be sure the tube flap is properly positioned before inflating the tire. **Always use a cage or safety chain**

during initial inflation.

It is important that the new C shaped side ring be used only with the new wheel with a bead hump. (See Fig. 6). The old style ring must be used only with the old tapered seat rim.

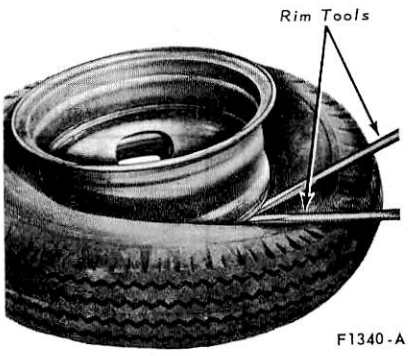

FIG. 9 Removing Tire From Rim

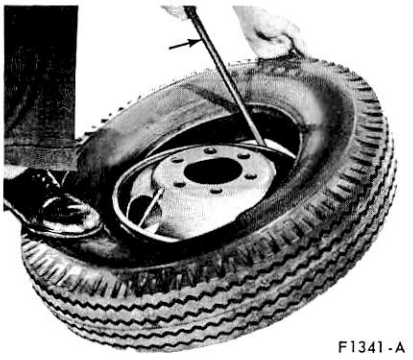

FIG. 10 Installing Tire First Bead on Wheel

PART 11-04 Wheels and Tires—Three Piece Rims

Applies to All 500-9000 Series Vehicles

COMPONENT INDEX	Page	COMPONENT INDEX	Page
TIRE REMOVAL AND MOUNTING – Three-Piece Rims	04-01	TIRE REMOVAL AND MOUNTING – Cast Spoke Wheels	04-02

DESCRIPTION

Three-piece rims are nondemountable for disc wheels or demountable for cast spoke wheels, Fig. 1, shows a dual wheel sectional view.

Demountable rims for cast-spoke wheels are secured by a lane at the back edge of each spoke, and a lug retained by a stud and nut at the edge of each spoke. **Refer to the first page of Group 11, Part-01 for safety procedures and illustrations.**

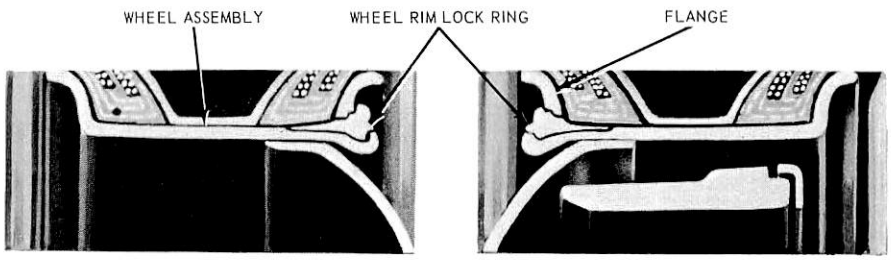

FIG. 1 Three-Piece Rim—Dual Wheel Sectional View

REMOVAL AND INSTALLATION

The tire must be completely deflated before removal, and the bead must not be damaged by a tire iron.

After installation, a tube tire should be inflated to recommended pressure, deflated, and then inflated again to insure that the tube is not folded inside the tire. Be sure the tube flap is properly positioned before inflating the tire.

TIRE REMOVAL AND MOUNTING—THREE-PIECE RIM

Tire mounting procedures are the same for disc wheels and for cast wheels equipped with the three-piece rims, escept that cast spoke wheels require special final centering and run-out adjustment.

Removing Tire From Wheel

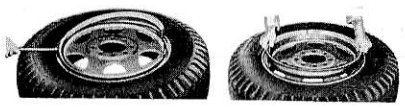
1. Place the wheel and deflated tire on the floor, with the ring up. Insert the straight end of the rim tool in the depression in the locking ring and loosen the tire bead by pressing down on the side ring (Fig. 2).
2. Insert the straight end of the rim tool in the notch provided in the locking ring, and pry the locking ring out of the gutter (Fig. 2). Lift out the locking ring, and remove the slide ring (Fig. 3).
3. Turn the wheel over and loosen the tie bead from the rim by hammering the hooked end of the rim tool between the rim flange and the tire bead. Pry the tire bead away from the taper all the way around the rim until the tire is free. Remove the tire.

Mounting Tire To Wheel

1. Position the wheel (gutter side up) on the floor. Soap both beads of the tire and position the tire on the rim.
2. Position the solid side ring on the tire, and insert the tapered toe of the split locking ring between the rim and the side ring (Fig. 3).
3. Using a soft hammer, drive the locking ring into place (Fig. 4). Start at one end of the split ring and progressively drive the ring into the gutter until the entire ring is seated (Fig. 4). **The ring must be entirely seated around the entire**

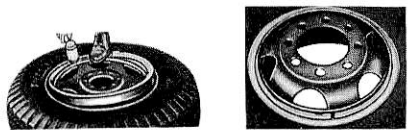
FIG. 2 Loosening Tire Bead and Locking Ring—Three-Ring Rim

circumference of the rim. The split ends must be engaged in the gutter, or the ring will be forced off violently during inflation or when the truck is driven. When inflating the tire do not stand in front of the ring.



F1462-A

FIG. 3 Removing Locking Ring and Positioning Locking Ring—Three-Piece Rim



F1463-A

FIG. 4 Starting Locking Ring and Locking Ring Installed—Three-Piece Rim

TIRE REMOVAL AND MOUNTING—CAST SPOKE WHEELS

Removal

1. To remove the rim and tire from a cast wheel, apply the parking brake, and block at least one wheel. Raise the vehicle and rim clamps.
2. With dual rear wheels, lift off the outer rim and tire, remove the spacer rim, and the inside rim and tire assembly.

Installation

1. To install the tire and rim on a dual wheel, place the inner tire and rim on the wheel hub. The rim must ride high enough up on the tapered retainer flange of the inner section of the wheel to prevent the assembly from sliding down on the tapered surface.
2. Position the spacer between the inner and outer rim.
3. Place the outer rim and tire assembly on the wheel, and install the 6 clamps (Fig. 5). First, draw up the top clamp tightly so that the spacer will push the inner rim up on the tapered surface of the inner section of the wheel, and then tighten the bottom clamp. This procedure tends to center the rim on the wheel.

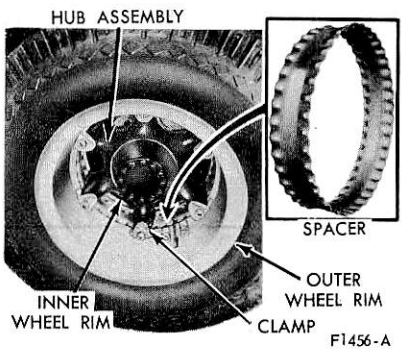


FIG. 5 Three-Piece Rim Installed on Cast Wheel

4. Tighten the remaining clamps alternately and evenly, and torque all wheel nuts to specification. Lateral or side run-out should not exceed 1/8 inch for front rims and 1/4-inch for dual rear rims, checked at the outer bead surface of the wheel.

PART 11-10 Wheels, Hubs and Bearings—Front (Except Front Drive)

Applies to F100-F-350, P-350, P-500 and E100/300

COMPONENT INDEX	Page	COMPONENT INDEX	Page
FRONT WHEEL ASSEMBLY		FRONT WHEEL GREASE	
Description	10-01	SEAL AND BEARING	
FRONT WHEEL BEARING		Removal and Installation	10-02
Adjustment	10-01	Repacking	10-02

DESCRIPTION

FRONT WHEEL ASSEMBLY

Each front wheel and tire assembly is bolted to its respective front hub and brake drum or rotor assembly. Two opposed tapered roller bearings are installed in each hub (Fig. 1, Part 11-02 and Figs. 3 and 4 of this Part). A grease retainer is installed at the inner end of the hub to prevent lubricant from leaking into the drum. The entire assembly is retained to its spindle by the locknut and/or adjusting nut and cotter pin, or an adjusting nut, lock nut combination (Figs. 3 and 4).

ADJUSTMENTS

FRONT WHEEL BEARING ADJUSTMENT

To check the wheel bearing adjustment, raise the front of the vehicle, grasp the tire at the sides, and alternately push inward and pull outward on the tire. If any looseness is felt, adjust the front wheel bearings.

F-100, 250, 350, ECONOLINE

1. Remove the hub cap and remove the grease cap from the hub.
2. Wipe any excess grease from the end of the spindle and remove the cotter pin and nut lock.
3. While rotating the wheel, torque the adjusting nut (Fig. 1, Part 11-02) to 17-25 ft-lb to seat the bearings.
4. Install the nut lock so that the cotter pin hole in the spindle is aligned with a slot in the nut lock.
5. Back off the adjusting nut and nut lock two slots of the nut lock and install the cotter pin.
6. Check the front wheel rotation. If the wheel rotates freely with no noticeable end play, install the grease cap. If the wheel is still loose, or it rotates roughly or noisily, the bearing cones and rollers and the cups are dirty or worn and should be cleaned or replaced.
7. Install the hub cap.

P-350 THRU 500

1. Remove the hub cap, if so equipped, and remove the grease cap from the hub.
2. Remove any excess grease from the end of the spindle and remove the adjusting nut cotter pin.
3. While rotating the wheel, torque the adjusting nut (See Fig. 4, under Disassembly and Assembly) to 40-55 ft-lbs to seat the bearings.
4. Back off the adjusting nut to the next castellation if necessary to align the nut with the cotter pin hole. Then, back off the adjusting nut two castellations and install the cotter pin.
5. Check the front wheel rotation. If the wheel rotates freely with no noticeable end play, install the grease cap. If the wheel is still loose, or it rotates roughly or noisily, the bearing cones and rollers and the cups are dirty or worn and should be cleaned or replaced.
6. Install the hub cap, if used.

ALL MEDIUM, HEAVY AND EXTRA HEAVY TRUCKS

Single Nut with Cotter Pin (5000-7000 Pound Front Axles)

1. While rotating the wheel, torque the adjusting nut to 70-100 ft-lb to seat the bearings.
2. Back off the adjusting nut 180 degrees (one half turn).
3. Hand tighten the adjusting nut finger tight (13-17 in-lb) while moving the top part of the tire in and out.

4. If the cotter pin hole lines up with a castellation in the nut, insert and secure a new cotter pin. If they do not line up, back off the adjusting nut to align a castellation with the first available cotter pin hole. Final bearing adjustment must provide .001-.010 end play.
5. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

DOUBLE NUT WITH LOCK RING (15000 POUND FRONT AXLE)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lbs to seat the bearings.
2. Back off the adjusting nut one complete turn (See Fig. 4, under Removal and Installation).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 and .010 inch end play between the wheel hub and spindle.
5. Install the lock ring.
6. Install the washer with the dimple indexed in one of the holes in the locking ring.
7. Install the lock nut and torque to 100-125 ft-lb.
8. Recheck the end play (Final limit .001 to .010 inch). Re-adjust if necessary.
9. Bend the washer outward to lock the nut in position.
10. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

DOUBLE NUT WITH DOUBLE WASHER (12000 POUND CENTER POINT AXLE)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearings.
2. Back off the adjusting nut one complete turn (See Fig. 4, under Disassembly and Assembly).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 to .010 inch end play between the hub and spindle.
5. Install the outer washer and lock nut and torque to 100-125 ft-lb.
6. Recheck the end play (final limit .001 to .010 inch). Re-adjust if necessary.
7. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

SINGLE NUT WITH COTTER PIN (16000, 18000 AND 20000 POUND FRONT AXLE)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearings.
2. Back off the adjusting nut one complete turn (See Fig. 4, under Disassembly and Assembly).
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut if necessary to align the nut castellations with the first available cotter pin hole.
5. Using the same cotter pin hole as a reference point, back off the adjusting nut **one additional castellation** to allow the wheel to rotate freely within the limits of .001 to .010 inch end play.
6. Insert and secure the cotter pin.
7. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

DOUBLE NUT WITH LOCK RING (9000 AND 12000 POUND FRONT AXLE)

1. While rotating the wheel in both directions, torque the adjusting nut to 100-125 ft-lb to seat the bearing.
2. Back off the adjusting nut one complete turn.
3. Again while rotating the wheel in both directions, retorque the adjusting nut to 40-55 ft-lb.
4. Back off the adjusting nut to obtain an initial .004 to .010 inch end play between the wheel hub and spindle.
5. Install the lock ring making sure the adjusting nut dowel is inserted into the lock ring.
6. Install the outer washer and lock nut. Torque to 100-150 ft-lb.
7. Recheck the end play (final limit .001 to .010 inch). Re-adjust if necessary.
8. Bend the washer outward to lock the outer nut in position.
9. Install the gasket and grease cap and adjust the brakes. **The final adjustment must not result in a preloaded bearing.**

DISASSEMBLY AND ASSEMBLY

FRONT WHEEL GREASE SEAL AND BEARING REMOVAL AND INSTALLATION AND/OR REPACKING

Wheel bearing lubricant has been changed from sodium base grease to lithium base grease.

Sodium base grease is not compatible with lithium base grease and should not be intermixed. Therefore, do not lubricate front and/or rear wheel bearings without first ascertaining the type of original wheel bearing lubricant. Usage of incompatible bearing lubricants could result in premature lubricant breakdown.

If bearing adjustment will not eliminate looseness or rough and noisy operation, the hub and bearings should be cleaned, inspected, and repacked with specified wheel grease. If the bearing cups or the cone and roller assemblies are worn or damaged, they should be replaced.

LIGHT VEHICLE-E100, E300, P350 AND P500

1. Raise the vehicle until the wheel and tire clear the floor and remove the wheel and tire from the hub. If the drums will not remove easily, back off the brake shoe adjusting screw so that the shoes do not contact the brake drum. Remove the grease cap from the hub.
2. Remove the cotter pin, nut lock, adjusting nut and washer from the spindle (Fig. 1, Part 11-02).
3. Remove the outer bearing cone and roller. Pull the hub and drum assembly off the wheel spindle. Then, remove and discard the grease retainer. Remove the inner bearing cone and roller from the hub. **Remove all traces of old lubricant from bearings, hubs, and axle spindle.**
4. Inspect the cups for scratches, pits or cracks. If the cups are worn or

damaged, remove them with a drift. Clean the inner and outer bearing cones and rollers with solvent and dry them thoroughly. **Do not spin the bearings dry with compressed air.**

5. Inspect the cones and rollers for cracks, nicks, brinelling, or seized rollers. Inspect the grease retainer and replace it if it is cracked, nicked, or dented. If the new grease retainer is leather, soak it in light engine oil for about 30 minutes before installation.
6. Cover the spindle with a clean cloth and brush all loose dust and dirt from the brake assembly. **Remove the cloth from the spindle carefully to prevent dirt from falling on the spindle.**
7. Install the inner and outer bearing cups in the hub with the appropriate installing Tool (Fig. 1). Be sure to seat the cups properly in the hub. The cups will be properly seated when they are fully bottomed. Pack the inside of the hub with C1AZ-19590-B wheel bearing grease. Fill the hub until the grease is flush with the inside diameters of both bearing cups. Pack the bearing cones and rollers with wheel bearing grease. Use a bearing packer for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.
8. Place the inner bearing cone and roller in the inner cup and install the grease retainer (Fig. 2) with the appropriate driving tool. Be sure that the retainer is fully bottomed. Install the hub and drum on the wheel spindle. **Keep the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads.**
9. Install the outer bearing cone and roller and the flat washer on the spindle, then install the adjusting nut.
10. Adjust the wheel bearing as outlined under Adjustments.

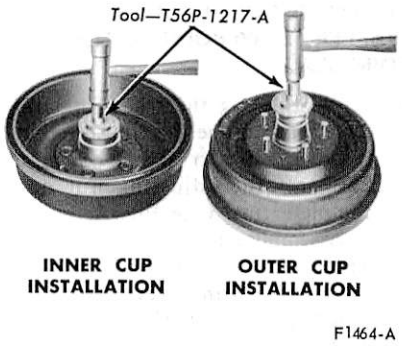

FIG. 1 Installing Bearing Cups

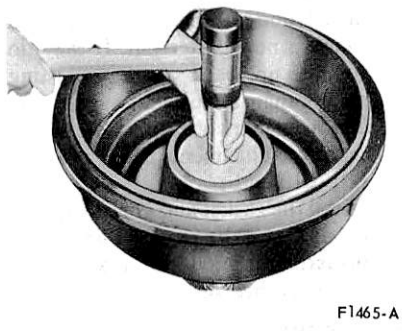

FIG. 2 Installing Grease Retainer

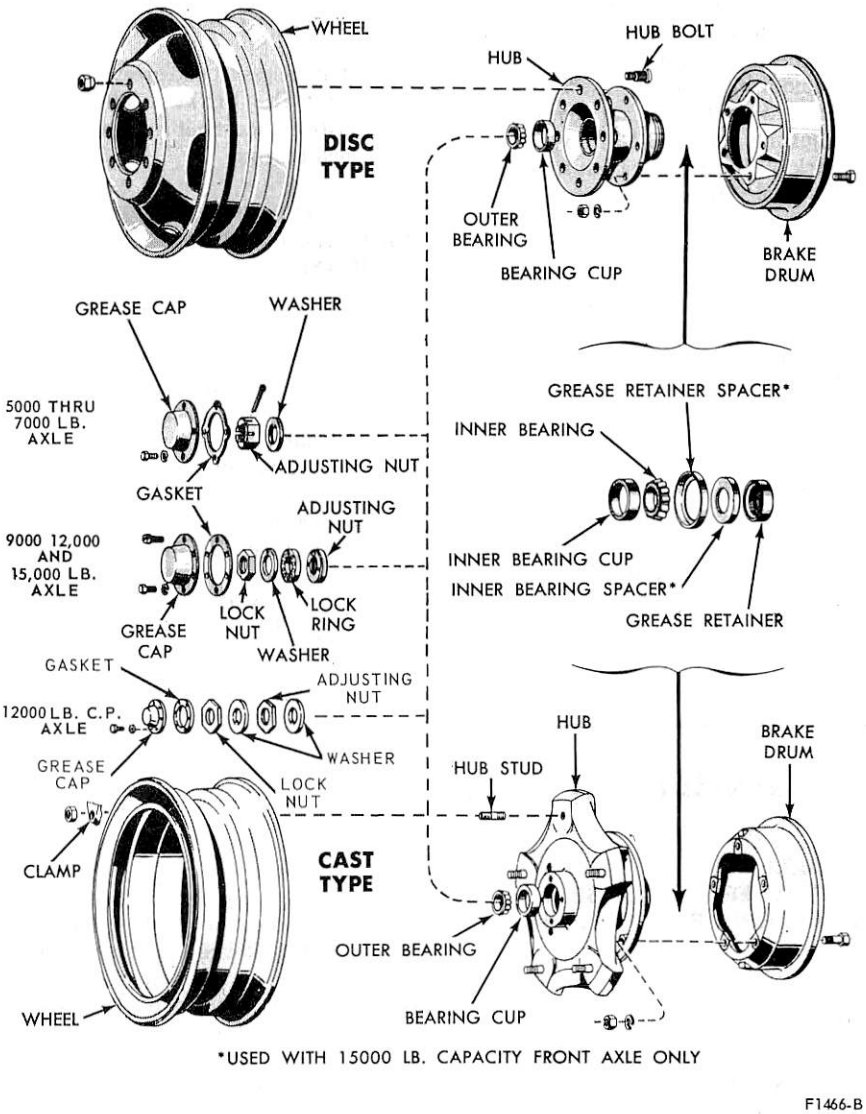

FIG. 3 Typical Front Hubs and Bearings

F100-F350 Disc Brake Equipped

The removal and installation of front wheel grease seals and bearings for disc brake equipped vehicles differs only in two respects from the procedure for drum brake equipped vehicles. First it is necessary to remove the brake caliper (refer to Group 12, Part 24). In this case the caliper can be suspended by wiring it above the hub and rotor.**Be careful not to twist or strain the flexible brake line.**

Then follow the procedure outlined for E100-E300 and P350-P500 with only one exception. A different tool, T37T-1190-B is required to install the special shielded grease seal. Finally, install the brake caliper following the steps given in Group 12, Part 24.

MEDIUM, HEAVY AND EXTRA HEAVY VEHICLES

There are two basic types of hub, disc and cast, shown in Fig. 3. The basic design of the hub bearings is the same in all hubs, but minor differences in size exist between the various models. The outer bearing attaching parts differ according to front axle weight capacity as indicated in Fig. 3. For further detailed views of hubs, bearings and grease retainers See Fig. 4.

1. Raise the vehicle until the tires clear the floor and install safety stands to support the front axle. Remove the grease cap and gasket from the hub.
2. To check the wheel bearing adjustment, alternately push inward and outward on the tire. If any excessive looseness is felt or there is no end play, adjustment of the front wheel bearings is necessary.
3. With 5000, 5500, 6000, 7000, 16000, 18000 or 20000 pound capacity front axles, remove the cotter pin, adjusting nut and flat washer from the spindle. With 9000, 12000 or 15000 pound capacity front axles, remove the lock nut, washer, locking ring and the adjusting nut and pin. With a 12000 pound capacity center point front axle, remove the lock nut, inner washer, adjusting nut and outer washer.
4. Inspect the condition of the spindle and nut threads to insure a free running nut when reassembling.
5. Remove the outer bearing cone and roller. Pull the hub and drum assembly off the spindle. Remove the inner bearing and seal using a brass drift. **Be careful not to damage the bearing cage.**
6. Remove all traces of old lubricant from the bearings, hubs and axle spindle. Inspect the cups for pitting, galling or unusual wear. If either cup is worn or damaged, remove it with a brass drift. Clean the inner and outer bearing cones and rollers with solvent and dry them throughly. **Do not spin the bearings dry with compressed air.**
7. Inspect the cones and rollers for pitting, galling or unusual wear. Particularly inspect the rollers for end wear and flat or rough spots. Replace all worn or damaged assemblies. It is recommended that the cone and roller assemblies and cups be replaced in sets.
8. Replace the grease retainer.
9. Cover the spindle with a clean cloth and brush all loose dust and dirt from the brake assembly. Remove the cloth from the spindle carefully to prevent dirt falling on the spindle.
10. Install the inner and outer bearing cups in the hub with the appropriate tool (Fig. 1). Check for proper seating of the new bearing cups by trying to insert a 0.0015 inch feeler gauge between the cup and wheel hub. The feeler gauge should not enter.
11. Pack the inside of the hub with Lithium base wheel bearing grease (C1AZ-19590-B). Fill the hub until the grease is flush with the inside diameters of both bearing cups. Pack the bearing cones and rollers with wheel bearing grease. Use a bearing packer for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.
12. Place the inner bearing cone and roller in the inner cup and install the grease retainer with the appropriate tool. Be sure the retainer is fully bottomed. On all synthetic type seals, coat the seal lips with wheel bearing grease (C1AZ-19590-B) before installing the hub and drum. On seals which are not coated on the OD with sealer by the supplier, coat the grease seal bore in the hub with a thin coat of non-hardening sealer prior to installing the grease seal.
13. Install the hub and drum on the wheel spindle. **Keep the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads.**
14. With 5000, 5500, 6000, 7000, 16000, 18000 or 20000 pound capacity front axles, install the outer bearing cone and roller and the flat washer on the spindle. Then, install the adjusting nut. With 9000, 12000 and 15000 pound capacity front axles, install the outer bearing cone and roller and the bearing adjusting nut. With a 12000 pound capacity center point front axle, install the washer and adjusting nut. Make the final bearing adjustment, under Adjustments.

MEDIUM, HEAVY AND EXTRA HEAVY VEHICLES (OIL LUBRICATION)

Stemco Seals and National Seals available as regular production otpions, provide sealing where oil is used for bearing lubrication. The tools required for Stemco Seal Installation are only available from the Stemco warehouse. Refer to Specifications for the tooling required. Fig. 5 illustrates a front wheel Stemco Seal Installation.

FRONT HUB SEAL INSTALLATION

Clean all parts before starting the installation of Stemco Seals.

1. Oil the spindle and push the axle ring flush against the axle face where applicable.
2. Remove all burrs from the wheel hub bore seal area and clean thoroughly.
3. Position the seal in the hub bore (Part Number Up).

Drive the seal into position using the correct tool. It must be perfectly square with the bore, and bottom evenly. Install the wheel and adjust the bearings. Install the Stemco hub cap. Remove the filler plug and add oil (ESW-M2C105-B SAE 90). Double check the oil level before releasing the vehicle for service. Oil level must be between the oil level line on the hub cap and 1/4-inch above the line.

National Seals (Fig. 6) are installed as follows:

1. Clean all parts, remove rough spots and install axle ring flush against face where applicable.
2. Position the seal into the hub (notice oil side marking) with drive tool and hammer into a press fit.
3. Install the wheel and adjust the bearings the same as for any seal installation. Install the see through hubcap and the retaining screws.
4. Remove the filler plug and add oil to level on see through hubcap.

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AXLE SHAFT		REAR WHEEL BEARING	
Removal and Installation	11-01	AND SEAL	
DESCRIPTION	11-01	Removal and Installation	11-01

DESCRIPTION

REAR WHEEL ASSEMBLY

The rear wheel hub and brake drum assembly is attached to studs on the rear axle shaft flange by three speed nuts. The wheel and tire mounts on the same rear axle shaft flange studs and is held against the hub and drum by the wheel nuts. The rear wheel bearing is pressed onto the axle shaft just inside the shaft flange, and the entire assembly is retained to the rear axle housing by the bearing retainer plate which is bolted to the housing flange.

REMOVAL AND INSTALLATION

REMOVAL OF AXLE SHAFT

The rear axle shafts, wheel bearings, and oil seal can be replaced without removing the differential assembly from the axle housing.

Synthetic wheel bearing seals are used. Removal and insertion of rear axle shafts must be performed with caution. The entire length of the shaft (including spline) up the seal journal must pass through the seal without cutting of the seal element during axle removal or installation will result in early seal failure.

1. Remove the wheel cover, wheel and tire from the brake drum.
2. Remove the nuts that secure the brake drum to the axle shaft flange, then remove the drum from flange.
3. Working through the hole provided in each axle shaft flange, remove the nuts that secure the wheel bearing retainer plate. Then pull the axle shaft assembly out of the axle housing (Fig. 1). **The brake backing plate must not be dislodged. Install one nut to hold the plate in place after the axle shaft is removed.**

REMOVAL OF REAR WHEEL BEARING AND SEAL

Synthetic seals must not be cleaned, soaked or washed in cleaning solvents.

Removal of the wheel bearings from the axle shaft makes them unfit for further use.

1. Loosen the inner retainer ring by nicking it deeply with a cold chisel in several places (Fig. 2). It will then slide off easily.
2. Remove the bearing from the axle shaft with Tool T60K-1225-A.
3. **Whenever a rear axle shaft is replaced, the oil seal must be replaced.** Remove the seal with Tool 1175-AB and a slide hammer.

INSTALLATION OF REAR WHEEL BEARING AND SEAL

1. Inspect the machined surface of the axle shaft and the axle housing for rough or other irregularities which would affect the sealing action of the oil seal. Check the axle shaft splines for burrs, wear or twist. Carefully

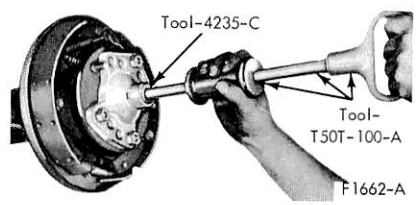

FIG. 1 Removing Axle Shaft

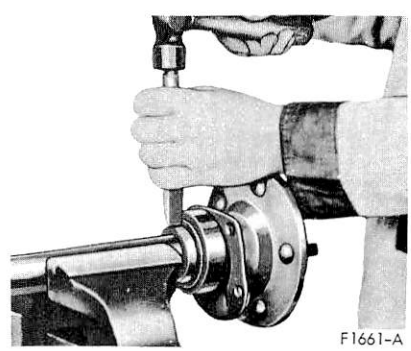

FIG. 2 Removing Rear Wheel Bearing Retainer Ring

remove any burrs or rough spots. Replace worn or damaged parts.
2. Lightly coat wheel bearing bores with axle lubricant.
3. Place the bearing retainer plate on the axle shaft, and press the new wheel bearing on the shaft with the tool shown in Fig. 3. **Do not attempt to press on both the bearing and the inner retainer ring at the same time.**
4. Using the bearing installation tool (Tool 4621-A), press the bearing inner retainer ring on the shaft until the retainer seats firmly against the bearing.
5. Install the new oil seal with the tools shown in Fig. 4. Wipe a small amount of oil resistant sealer on the outer edge of the seal before it is installed. **Do not put sealer on the sealing lip.**

INSTALLATION OF AXLE SHAFT

1. Carefully slide the axle shaft into the housing so that the rough forging of the shaft will not damage the oil seal. Start the axle splines into the side gear, and push the shaft in until the bearing bottoms in the housing.
2. Install the bearing retainer plate and the nuts that secure it. Torque the nuts to specification.
3. Install the brake drum and the drum attaching (Tinnerman) nuts.
4. Install the wheel and tire on the drum. Install the wheel cover.

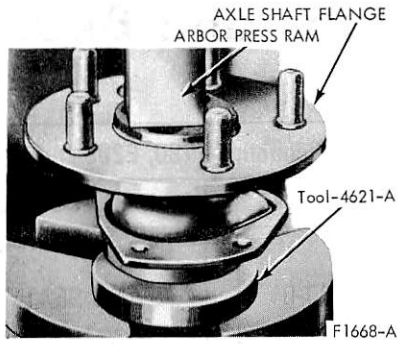

FIG. 3 Installing Rear Wheel Bearing

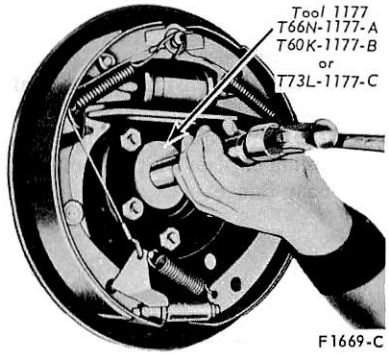

FIG. 4 Installing Rear Wheel Bearing Oil Seal

PART 11-12 Wheel Hubs and Bearings— Front Wheel Drive

ADJUSTMENTS	12-01	DISASSEMBLY AND ASSEMBLY	12-07
DESCRIPTION	12-01	REMOVAL AND INSTALLATION	12-03

DESCRIPTION

Front drive assemblies are available for Bronco, F-100, F-250 and F-600 vehicles.

ADJUSTMENTS

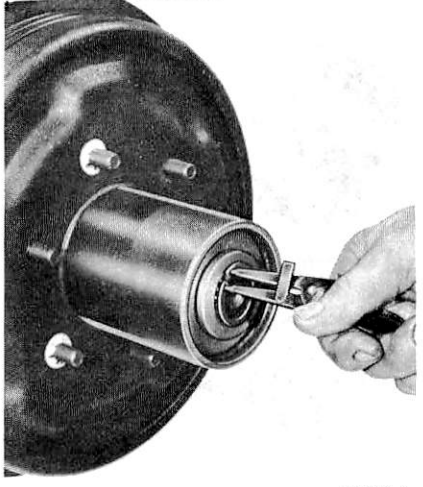
FRONT WHEEL BEARING ADJUSTMENT

BRONCO AND F-100

1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw if necessary.
3. Remove the front hub grease cap and the driving hub snap ring (Fig. 1).
4. Remove the splined driving hub and the pressure spring. This may require a slight prying assist (Fig. 2).
5. Remove the wheel bearing lock nut and lock ring.
6. Using Tool T59T-1197-B and a torque wrench, tighten the bearing adjusting nut to 50 ft-lbs while rotating the wheel back and forth to seat the bearing.
7. Back off the adjusting nut approximately 90 degrees.
8. Assemble the lock ring by turning the nut to the nearest notch where the dowel pin will enter.
9. Install the outer lock nut and torque to 80-100 ft-lbs. Final end play of the wheel on the spindle should be 0.001 to 0.010 inches.
10. Install the pressure spring and driving hub, the driving hub snap ring and after applying non-hardening sealer to the seating edge of the grease cap, install the grease cap. If equipped with free-running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Installation. The non-lockout type hub is shown in Fig. 3.
11. Adjust the brake if it was backed off.
12. Remove the safety stands and lower the vehicle.

F-250

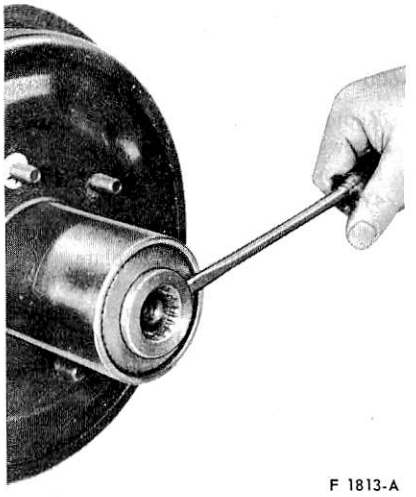
1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw, if necessary. Remove the wheel cover, if installed.



F 1812-A

FIG. 1 Removing Snap Ring

3. Remove the front hub grease cap. Remove the driving hub retaining snap ring and slide the splined driving hub from between the axle shaft and the wheel hub (Fig. 2). Remove the driving hub spacer. (If equipped with free running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Removal in Group 15).
4. With Tool T59T-1197-B, remove the lock nut and lock ring from the spindle.



F 1813-A

FIG. 2 Removing Splined Driving Hub

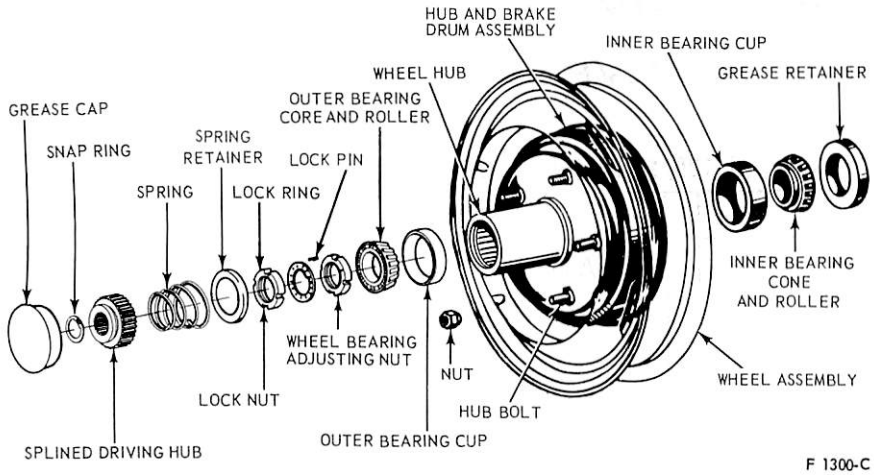


FIG. 3 Front Hub Installation—Four-Wheel Drive-non lockout type

5. Using Tool T59T-1197-B and a torque wrench, tighten the bearing adjusting nut (Fig. 2, Part 11-02) to 50 ft-lb, while rotating the wheel back and forth to seat the bearings.
6. Back the adjusting nut off approximately 90 degrees. Assemble the lock ring by turning the nut to the nearest notch where the dowel pin will enter.
7. Install the outer lock nut and torque to 80-100 ft-lbs. Final end play of the wheel on the spindle should be 0.001 to 0.010 inch.
8. **Install the driving hub, spacer, snap ring and hub grease cap. Apply a thin coat of non-hardening sealer to the setting edge of the grease cap, before installation. (If equipped with free-running lock-out hubs, refer to Front Wheel Drive Lock-Out Hub Installation).**
9. Adjust the brake, if backed off to permit drum removal.
10. Remove the safety stands and lower the vehicle.

F-600

1. Remove the outer hub cap retaining screws, and remove the cap.
2. Remove the retaining lock ring (Fig. 4).
3. Remove the retaining screws and remove the splined drive plate.
4. Bend the tab of the lock washer away from the lock nut and remove the lock nut (Fig. 5).
5. Remove the lock washer and **discard** it.
6. While rotating the wheel back and forth to correctly seat the bearings, torque the adjusting nut to 50 ft-lbs.
7. Back off the adjusting nut from 1/4 to 1/3 turn.
8. Position a **new** lock washer against the adjusting nut and apply a film of oil to the outer face of the lock washer.
9. Run the lock nut up against the lock washer and torque it to 100-150 ft-lbs.
10. Bend one tab of the lock washer over the adjusting nut.
11. Bend one tab of the lock washer (in the opposite direction) over the lock nut. **Use a blunt tool when bending the tabs to avoid making any chips which could cause serious bearing damage.**
12. Apply Silastic Sealer to the front and rear mounting faces of the splined drive plate.
13. Position the drive plate, install the retaining screws and torque them to specifications.
14. Install the retaining lock ring.
15. Position the outer hub cap and install the retaining screws and torque them to specifications.

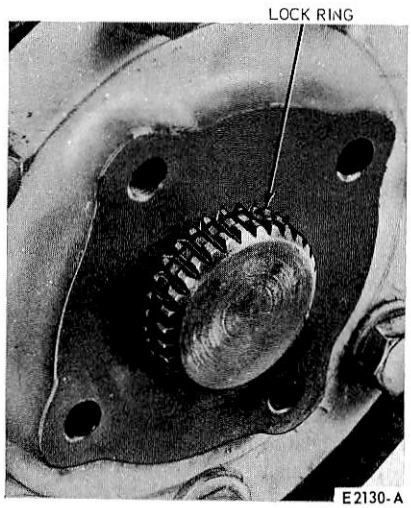

FIG. 4 Access to Lock Ring

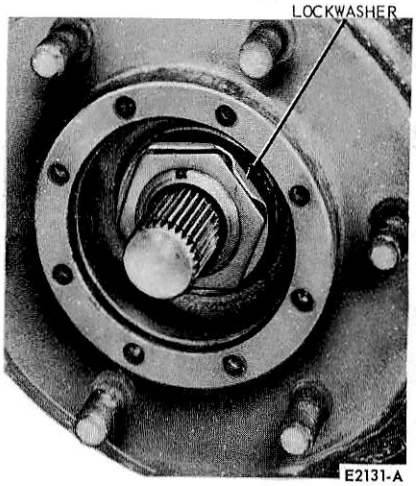

FIG. 5 Lock Nut and Washer Assembled

REMOVAL AND INSTALLATION

LOCK-OUT HUB (INTERNAL TYPE)

BRONCO, F-100, F-250 (3300 LB AXLE)

Removal

1. Remove the lock-out hub screws and washers (refer to Fig. 6).
2. Remove the hub ring and the knob. Wipe the parts clean.
3. Remove the internal snap ring from the groove in the hub.
4. Remove the cam body ring and clutch retainer (as an assembly) from the hub. Disassemble the parts.
5. Remove the axle shaft snap ring. It may be necessary to push inward on the gear and pull out on the axle with a bolt to make the snap ring removal easier.
6. Remove the drive gear and clutch gear. A slight rocking of the hub may make them slide out easier.
7. Remove the coil spring.
8. Remove the spring retainer ring.

Installation

1. Grease the inner hub with high speed grease (Fig. 7).
2. Install the spring retainer ring, positioned as shown with recessed undercut area going in first. Be sure it seats against the bearing (Fig. 8).
3. Install the coil spring with large end entering first (Fig. 9).
4. Install the axle shaft sleeve and ring and the inner clutch ring. Notice that the teeth are meshed together in a locked position for easy assembly. It may be necessary to rock the hub back and forth for spline alignment. Keep the two gears in locked position (Fig. 10).
5. Install the axle shaft snap ring. Push inward on gear, and if necessary, pull out axle shaft with bolt to allow clearance in groove for snap ring on the axle shaft. Be sure snap ring is fully seated in the smap ring groove of the shaft (Fig. 11).
6. Install the actuating cam body ring into the outer clutch retaining ring. Assemble into hub (Fig. 12).
7. Install the internal snap ring. Be sure snap ring is fully seated in the snap ring groove of the hub (Fig. 13).
8. Apply a small amount of Lubriplate Grease on the ears of the cam (Fig. 14).
9. Apply a small amount of Parker O-ring lube in groove of actuating knob before assembling outer O-ring (Fig. 14).
10. Assemble knob in hub ring and assemble to axle with knob in locked position. Assemble screws and washers alternately and evenly, making sure the retainer ring is not cocked in the hub.
11. Torque the six lock-out hub screws to 35 to 40 inch pounds. Be sure the washers are under each retaining screw. At first the lock-out hubs will probably seem hard to engage and disengage, but after mileage they should loosen up for easier operation. Either lock-out hub will fit either wheel.

Do not drive vehicle until you are sure that both lock-out hubs are engaged or disengaged. When vehicle is driven in water deep enough to cover the hubs, it is recommended that the internal parts be disassembled and inspected for possible water or dirt. After inspection, relubricate all parts before assembly to prevent rusting or corrosion.

LOCK-OUT HUB (EXTERNAL TYPE)

F-250 (3500 LB AXLE)

Removal

1. Remove the lock-out hub screws and washers (refer to Fig. 15), and discard them.

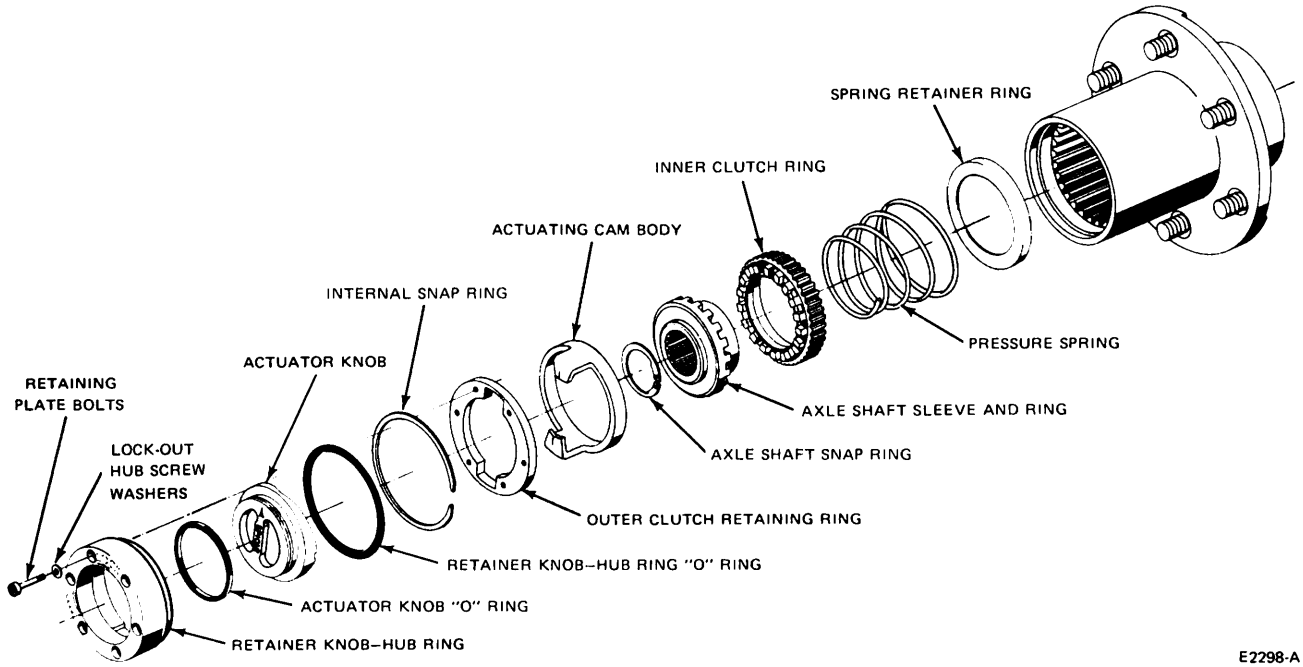

FIG. 6 Lock-Out Hub Internal Type—Bronco, F-250 (3300 Lb. Axles) Optional F-100

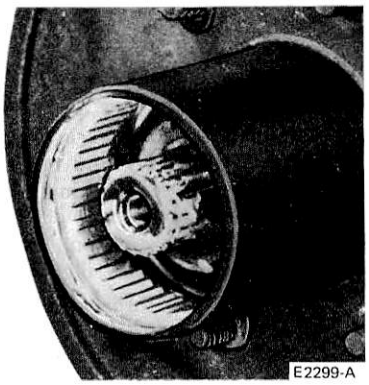

E2299-A

FIG. 7 Grease Application

2. Loosen the gear hub housing and slide away from the hub and drum assembly.
3. Remove the inner metal gasket (and discard it), the gear hub housing, and remove and discard the outer gasket. Wipe clean the exposed parts.
4. Remove the snap ring while holding pressure on the clutch gear.
5. Ease the clutch gear and pressure spring out of the assembly. The actuator knob should be in the lock position for this step.
6. Turn the actuator knob to the free position. With a drift, drive the lock pin out of the assembly.
7. Remove the actuating cam from the knob.
8. Remove the knob retainer snap ring and remove the knob from the knob retainer.
9. Using a capscrew pull out slightly on the axle shaft and remove the snap ring which retains the bushing and inner clutch gear assembly.
10. Remove these parts and disassemble. If wear or damage are evident on either the inner or outer clutch gear they should both be replaced as a set.

Installation

Before assembling lock-out hubs inspect the splines of the axle shaft making sure they are free of any possible nicks or burrs.

Threaded screw holes in the wheel hub should be cleaned before assembling new retainer screws. These holes can be cleaned by directing compressed air into the threaded holes.

1. Apply a small amount of MOLY XL hi-speed grease to the back face and the thrust face of the bushing, also to the splines of the inner clutch gear. Assemble inner clutch gear into bushing. Install the bushing and inner clutch gear onto axle shaft, making sure the splines of the inner clutch gear are aligned with the splines of the axle shaft, as shown (Fig. 16).
2. **Install a new snap ring. If necessary, pull out axle shaft with capscrew to allow clearance in groove for snap ring on axle shaft. Be sure snap ring is fully seated (Fig. 17).**
3. Apply a small amount of Parker O-ring lubricant on the actuator knob, making sure knob is completely lubricated in the area shown. Assemble O-ring onto actuating knob.
4. **Install the actuating knob into the knob retainer with arrow pointing to free position. Install the knob retainer snap ring. Spread snap ring with snap ring pliers. Use a small screwdriver to position the snap ring in the groove of the knob (Fig. 18).**
5. Install the actuating cam onto the knob, aligning ears of the cam with the slots of the retainer. Position parts on a small piece of wood as shown. Assemble the lock pin through the groove of the cam and holes in the actuating knob. Be sure ends of the pin are flush with the outside diameter of the cam (Fig. 19).
6. Turn actuator knob to **lock** position. Apply a small amount of MOLY XL hi-speed grease to both grooves of the cam as shown (Fig. 20).
7. Install the pressure spring and outer clutch gear. Compress the pressure spring by forcing down on clutch gear and assemble snap ring. Make sure snap ring is secure in the groove of the cam. Turn actuator knob to free position. Assemble six dished washers to the six retainer screws exactly as shown (Figs. 21 and 22).
8. Install 2 screws with correctly positioned washers into the knob retainer. This will properly line up the parts in steps 9 and 10. Apply a small amount of hi-speed grease to the outer spline and teeth of the outer clutch gear. Remove any excess lubricant from the gasket surface of the retainer.
9. Install a new outer retainer gasket. Assemble gear hub housing by aligning the splines of the housing with those of the outer clutch gear as shown. Assemble a new inner (metal) gasket on hub housing (Fig. 23).
10. Position the lock-out hub subassembly to axle assembly using the two new retainer screws as pilots to assure that the holes of the gasket are in alignment with the holes of the wheel hub. Tighten retainer screws to secure the lock-out hub. Turn actuator knob to lock position.
11. Install the remaining four new retainer screws with washers. Tighten screws evenly. Torque to 30-35 ft-lbs. The lock-out may be hard to engage and disengage, however after use, they should loosen up for easier operation. Either lock-out will fit either wheel.
12. **Do not drive vehicle until both lock-out hubs are either engaged or disengaged.**

DISASSEMBLY AND ASSEMBLY

FRONT WHEEL GREASE SEAL AND BEARING REMOVAL AND INSTALLATION AND/OR REPACKING

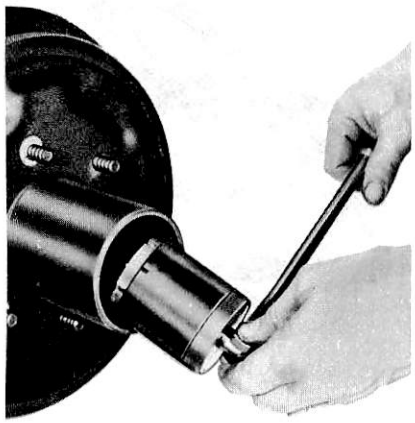
Wheel bearing lubricant has been changed from sodium base grease to lithium base grease.

Sodium base grease is not compatible with lithium base grease and should not be intermixed. Therefore, do not lubricate front and/or rear wheel bearing without first ascertaining the type of original wheel bearing lubricant. Usage of incompatible bearing lubricants could result in premature lubricant breakdown.

If bearing adjustment will not eliminate looseness or rough and noisy operation, the hub and bearings should be cleaned, inspected, and repacked with specified wheel grease. If the bearing cups or the cone and roller assemblies are worn or damaged, they should be replaced.

BRONCO AND F-100

1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw if necessary.
3. Remove the front hub grease cap and driving hub snap ring (Fig. 1).
4. Remove the splined driving hub and the pressure spring. This may require a slight prying assist (Fig. 2).
5. **Remove the wheel bearing lock nut, lock ring, and adjusting nut (Fig. 24), using Tool T59T-1197-B.**
6. Remove the hub and drum assembly. The outer wheel bearing and spring retainer will slide out as the hub is removed (Fig. 25).
7. Carefully drive the inner bearing cone and grease seal out of the hub



F 1814-A

FIG. 24 Lock nut, Lock Ring and Adjusting Nut Removal

F 1815-A

FIG. 25 Hub, Drum and Outer Bearing Removal

F 1816-A

FIG. 26 Inner Bearing Cone and Grease Seal Removal

(Fig. 26) using T69L-1102-A.

8. Inspect the bearing cups for pits or cracks. If necessary, remove them with a drift (Fig. 27). **If new cups are installed, install new bearings.** The bearings should be lubricated with C1AZ-19590-B wheel bearing grease. Clean all old grease from the hub. Pack the cones and rollers. If a bearing packer is not available, work as much lubricant as possible between the rollers and the cages.
9. Position the inner bearing cone and roller in the inner cup and install the grease retainer.
10. Carefully position the hub and drum assembly on the spindle.
11. Install the outer bearing cone and roller and the adjusting nut.
12. Using Tool T59T-1197-B and a torque wrench, tighten the bearing adjusting nut to 50 ft-lbs while rotating the wheel back and forth to seat the bearings.
13. Back off the adjusting nut approximately 90 degrees.
14. Assemble the lock ring by turning the nut to the nearest notch where the dowel pin will enter.
15. Install the outer lock nut and torque to 80-100 ft-lbs. Final end play of the wheel on the spindle should be 0.001 to 0.010 inches.
16. Install the pressure spring and driving hub snap ring and after applying non-hardening sealer to the seating edge of the grease cap, and install the grease cap. If equipped with free-running lock-out hubs, refer to Removal and Installation for the type of hub involved.
17. Adjust the brake if it was backed off.
18. Remove the safety stands and lower the vehicle.

F-250

1. Raise the vehicle and install safety stands.
2. Back off the brake adjusting screw, if necessary. Remove the wheel cover, if installed.
3. Remove the front hub grease cap. Remove the driving hub retaining snap ring (Fig. 2, Part 11-02) and slide the splined driving hub from between the axle shaft and the wheel hub. Remove the driving hub spacer. If equipped with free-running lock-out hubs, refer to Removal and Installation for the type of hub involved.
4. **With Tool T59T-1197-B, remove the lock nut, washer, and wheel bearing adjusting nut (Fig. 3) from the spindle. Remove the wheel, hub and drum as an assembly. The wheel outer bearing will be forced off the spindle at the same time. Protect the spindle and inner bearing cone from dirt.**
5. Remove the grease retainer and the inner bearing cone and roller assembly from the hub with Tool 1175AB, and T50T-100-A. Discard the grease retainer.
6. Clean the lubricant off the inner and outer bearing cups with solvent and inspect the cups for scratches, pits, excessive wear, and other damage. If the cups are worn or damaged, remove them with a drift.
7. Thoroughly clean the inner and outer bearing cones and rollers with solvent, and dry them thoroughly. **Do not spin the bearings with compressed air.**

Inspect the cone and roller assemblies for wear or damage, and replace them if necessary. The cone and roller assemblies and the bearing cups should be replaced as a unit if damage to either is encountered.

8. Thoroughly clean the spindle and the inside of the hub with solvent to remove all old lubricant.

Cover the spindle with a clean cloth, and brush all loose dust and dirt from the brake assembly. **To prevent getting dirt on the spindle, carefully remove the cloth from the spindle.**

9. If the inner bearing cup was removed, install the cup or a new cup in the hub. **Be sure to seat the cup properly in the hub.**
10. Install the outer bearing cup in the hub with a suitable tool. **Be sure the cup is properly seated in the hub.**
11. Pack the inside of the hub with CIAZ-19590-B lubricant. Add lubricant to the hub only until the grease is flush with the inside diameter of both bearing cups.
12. **All old grease should be completely cleaned from the bearings before repacking them with new grease. Pack the bearing cone and roller assemblies with C1AZ-19590-B lubricant. A bearing packer is desirable for this operation. If a packer is not available, work as much lubricant as possible between the rollers and cages. Lubricate the cone surfaces with grease.**
13. Place the inner bearing cone and roller assembly in the inner cup, and install the new grease retainer. **Be sure that the retainer is properly seated.** Coat the grease retainer sealing lip with a liberal amount of CIAZ-19590-B lubricant.
14. Install the wheel, hub, and drum assembly on the wheel spindle. **Keep the hub centered on the spindle to**

prevent damage to the grease retainer or the spindle threads.

15. Install the wheel outer bearing cone and adjusting nut. Adjust the front wheel bearings as detailed in Adjustments under Front Wheel Bearing Adjustment.

F-600

1. Remove the wheel and tire from the hub and drum. Remove the outer hub cap retaining screws, and remove the cap.
2. Remove the retaining lock ring (Fig. 3).
3. Remove the retaining screws and remove the splined drive plate.
4. Bend the tab of the lock washer away from the lock nut and remove the lock nut (Fig. 4).
5. Remove the lock washer and **discard it.**
6. Remove the adjusting nut.
7. Remove the hub and drum carefully from the spindle. Cover the spindle to protect it from dirt and foreign material. If the drum is difficult to remove, back off the brake adjustment to provide clearance.
8. Carefully remove the inner bearing and seal.
9. Clean the bearing recess and using a suitable solvent, clean the bearings. **Do not spin dry with compressed air.** Repack the bearings with grease after drying thoroughly. Inspect the bearing cups. If cracked, pitted, or otherwise damaged, they should be replaced. If they are replaced, the bearings should also be replaced.
10. The cups can be removed using a hammer and a drift.
11. Install the new cups using Tool T68T-1174-AB for the inner bearing cup and Tool T68T-1173-AB for the outer bearing cup.
12. **Install the inner bearing, lubricate and install the grease seal using Tool T68T-1173-AC.**
13. Position the hub and drum on the spindle.
14. Install the outer bearing and the adjusting nut. Install the wheel and tire on the hub and drum.
15. While rotating the wheel back and forth to correctly seat the bearings, torque the adjusting nut to 50 ft-lbs.
16. Back off the adjusting nut from 1/4 to 1/3 turn.
17. Position a **new** lock washer against the adjusting nut and apply a film of oil to the outer face of the lock washer.
18. Run the lock nut up against the lock washer and torque it to 100-150 ft-lbs.
19. Bend one tab of the lock washer over the adjusting nut.
20. Bend one tab of the lock washer (in the opposite direction) over the lock nut. **Use a blunt tool when bending the tabs to avoid making any chips which could cause serious bearing damage.**
21. Apply Silastic Sealer to the front and rear mounting faces of the splined drive plate.
22. Position the drive plate, install the retaining screws and torque them to specifications.
23. Install the retaining lock ring.
24. Position the outer hub cap and install the retaining screws.

FIG. 27 Bearing Cup Removal

PART 11-14 Wheel Hubs and Bearings— Rear (Full Floating Axle)

Applies to All 250 and Higher Series Vehicles

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION	14-01	DISASSEMBLY AND ASSEMBLY	14-02

DESCRIPTION

On all the full-floating axle wheel hubs with tapered roller bearings, a seal is installed behind the inner bearing to keep the wheel bearing lubricant from the brake lining and brake drum (Figs. 1 and 2).

The wheel bearings are packed with wheel bearing lubricant (C1AZ-19590-B) to provide initial lubrication until axle lubricant flows into the wheel hubs and bearings during vehicle operation. On these axles the wheel hub is vented through the axle housing vent. The seal assembly (500-9000 Series) mounts on the wheel hub and seals on a wear sleeve (wiper) which is installed on the axle housing tube (Fig. 2).

The wear sleeves (500-9000 Series) must be installed squarely on the axle housing using the appropriate tools (Fig. 3). **Do not use heat on the wear**

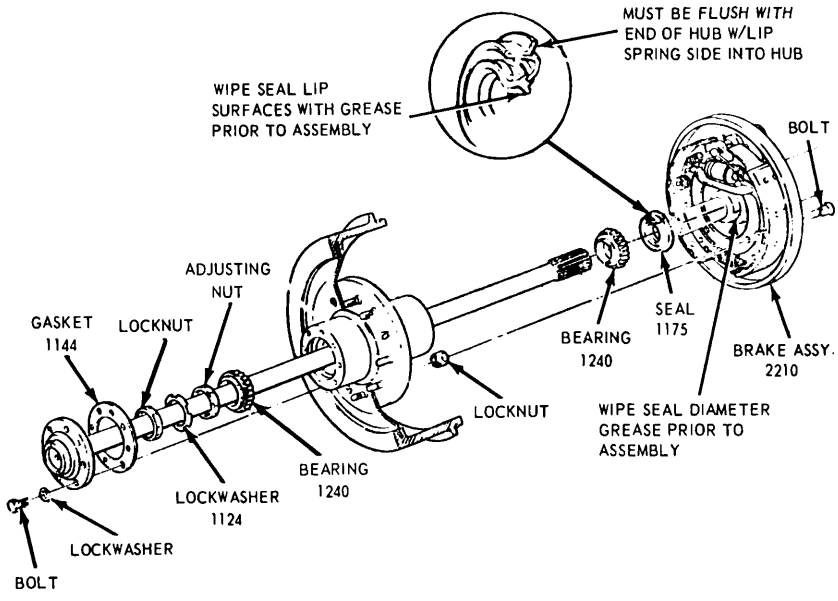


FIG. 1 Rear Wheel Hub—Dana Full-Floating Axle—Models 60, 60-3E, and 70

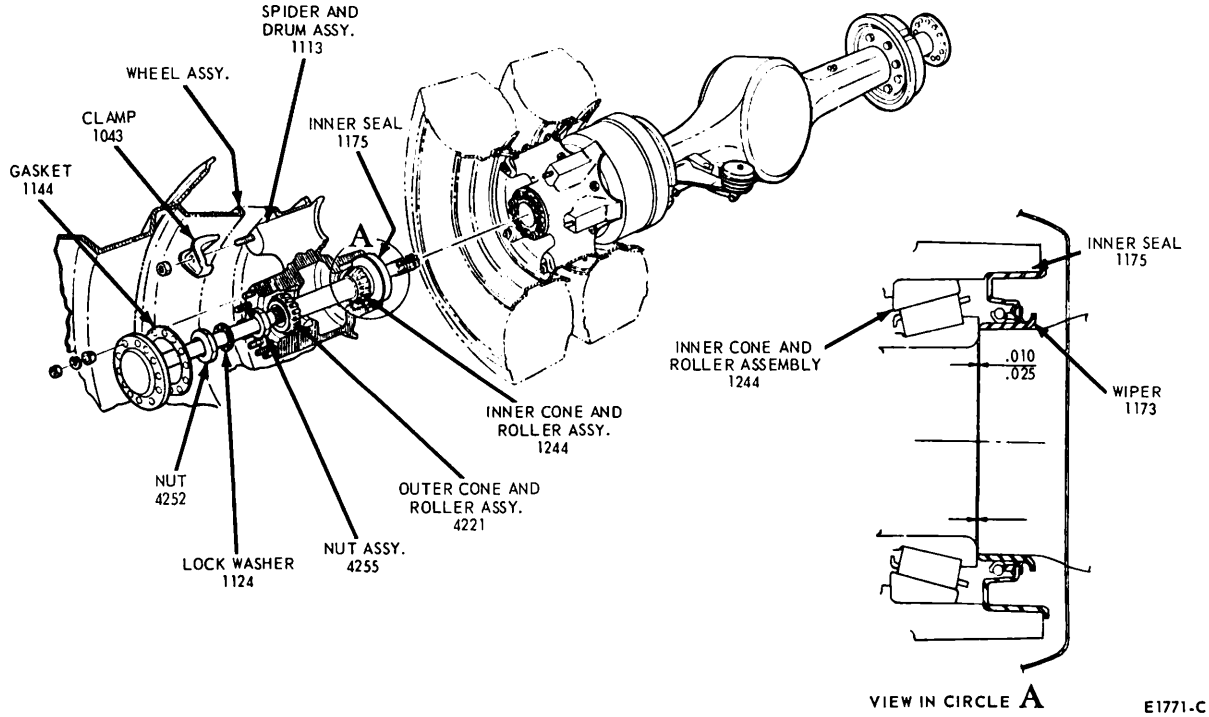

FIG. 2 Typical Rear Wheel Hub—Full-Floating Axle—500-9000 Series

sleeves to facilitate installation. Use the proper tool as shown in Fig. 3. The sleeves are designed with flanges to eliminate the possibility of installing the sleeves backwards. Although preservative has been applied to the wear sleeve prior to packaging, a light oil (SAE-10 or its equivalent) should be applied to the wear sleeve to facilitate assembly of the sleeve to the axle housing. After installation of the wear sleeve, the clearance between the end of the wear sleeve and inner wheel bearing shoulder should be 0.010 to 0.025 inches (Fig. 2).

The seal assembly is to be installed in the wheel hub. The garter spring should be checked to assure the spring is in the spring groove behind the primary seal lip after the seal is in position. Before installing the wheel, apply grease (C1AZ-19590-B) between the lips of the seal.

The wheel bearing must be thoroughly cleaned and repacked with lithium base grease (C1AZ-19590-B) before installing the wheel assembly.

To prevent damage to the primary and secondary lips of the seal assembly, a locator sleeve or tool should be used to guide the hub and drum onto the axle. A new seal assembly must be installed whenever a wheel is removed.

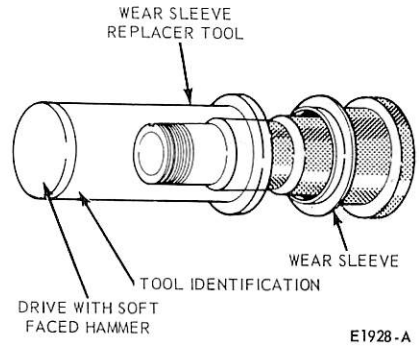

FIG. 3 Tool Application of Wear Sleeve (Wiper) Installation

DISASSEMBLY AND ASSEMBLY

BEARINGS, CUPS AND SEALS

F-250, (4 X 2 AND 4 X 4), F-350, E-300, P-350, AND P-400 SERIES

1. Set the parking brake and loosen the axle shaft retaining bolts (Fig. 1).
2. Raise the rear wheels off the floor and place work stands under the rear axle housing so that the axle is parallel with the floor. Back off the rear brake adjustment, if necessary.
3. Remove the axle shaft retaining bolts and discard them.
4. Remove the axle shaft and discard the gasket.
5. Remove the wheel lock nut, lock washer and wheel bearing adjustment nut using Tool T70T-4252-D, or T70T-4252-E. **Under no condition should the lock nut be removed with a chisel.** Discard the lock washer.
6. With the type of wheel jack shown in Fig. 4, raise the wheel to the point that all weight is removed from the wheel bearings. Remove the outer bearing cone. Now, pull the wheel assembly **straight** out and away from the axle.
7. Thoroughly clean the spindle of the axle housing.
8. With a brass drift, and care to prevent damaging the bearing cage, drive the inner bearing cone and inner seal out of the wheel hub.
9. Clean all old grease and axle lubricant out of the wheel hub.
10. Inspect the bearing races and rollers for pitting, galling or erratic wear patterns. Inspect the rollers for end wear. Replace the bearings if worn or damaged.
11. If the bearing cups are to be replaced, drive them out with a brass drift. Install the new cups with a tool such as OTC 27797.
12. Check for proper seating of the new bearing cups by trying to insert a 0.0015 inch feeler gauge between the cups and the wheel hub.
13. Pack each bearing cone and roller assembly with a bearing packing tool, using C1AZ-19590-B (ESA-MIC75-B) long life lubricant.
14. Place the inner bearing cone and roller assembly in the wheel hub. Install a new hub inner Seal using Tool T73T-1190-A.
15. Position the wheel assembly at the axle housing. Wrap the threads of the spindle with electricians tape. Carefully slide the wheel assembly **straight (to avoid seal damage) onto the axle housing spindle.** Remove the electricians tape.
16. Install the outer wheel bearing and start the bearing adjuster nut. Remove the wheel jack.
17. Torque the adjusting nut to 50-80 ft-lbs while rotating the wheel. Back off (loosen) the adjusting nut 3/8 of a turn using Tool T70T-4252-D or T70T-4252-E.
18. Install a new lock washer coated with axle lube and smooth side out. Install the lock nut (Tool T70T-4252-D or T70T-4252-E). Torque the lock nut to 90-110 ft-lbs. With the lock nut at proper torque, the wheel assembly must rotate freely and with an end play of 0.001-0.010 inch. **Be sure of this specification. Check it closely with suitable dial indicator set up. Do not preload the bearings.**

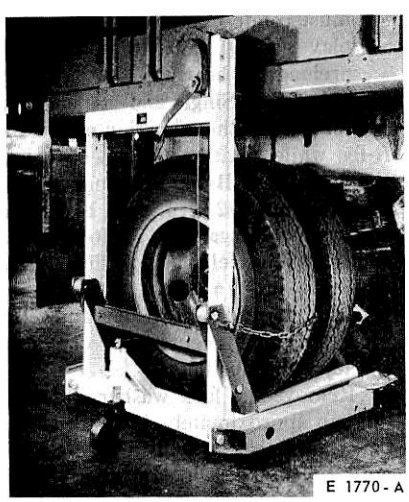

FIG. 4 Typical Wheel Jack

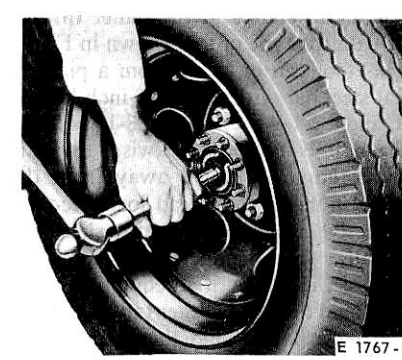

FIG. 5 Axle Shaft Removal—Tapered Dowels

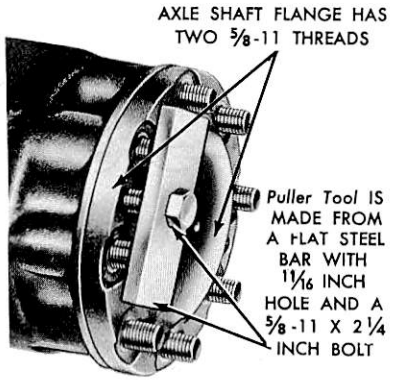

FIG. 6 Axle Shaft Puller

19. With a satisfactory end play and freely turning wheel bend two lock washer tabs inward over flats of the adjusting nut and two tabs outward over flats of the lock nut.
20. **Install the axle shaft, new axle flange gasket, lock washers and new axle shaft retaining bolts. Torque the lock bolts to 40-50 ft-lbs.**
21. Adjust the brakes. Then, remove the work stands and lower the vehicle.

500-9000 SERIES

1. Release the parking brake and loosen the axle shaft stud nuts.
2. **Raise the rear wheels off the floor and place the work stands under the rear axle housing so that the axle is parallel with the floor. Back off the rear brake adjustment.**
3. Remove the axle shaft stud nuts.
4. If tapered dowels are installed in the axle shaft flange, place a drift in the center of the flange and strike it sharply to loosen the dowels (Fig. 5). Remove the axle shaft.

On axles where tapered dowels are not used, two puller threads (5/8-11) are provided in the axle shaft flange. These axle shafts may be pulled with a slide hammer installed in the puller threads or with the type of tool shown in Fig. 6. This tool can be made from a piece of flat steel bar with an 11/16 inch hole in it, and a 2 1/4 inch long 5/8-11 bolt. As the bolt is turned clockwise, the axle shaft flange is pulled away from the wheel hub. If the thread load becomes excessive when pulling an axle shaft, install a second puller on the opposite side of the flange, if so equipped.

5. Bend the lock washer tab away from the lock nut, and then remove the lock nut, lock washer, and the adjusting nut.
6. With the type of wheel jack shown in Fig. 4, raise the wheel to the point **that all wheel weight is removed from the wheel bearings. Remove the outer bearing cone. Now, pull the wheel straight out and away from the axle.**
7. Inspect the inner seal wear sleeve on the axle housing spindle for signs of wear or pitting. If necessary to replace the wear sleeve, use a hammer and a cold chisel. Being careful not to damage the seal journal of the axle housing, make two evenly spaced indentations in the wear sleeve surface and slip the wear sleeve off the axle housing. Thoroughly clean the spindle of the axle housing. Then, position a new **proper size** wear sleeve squarely to the axle housing spindle and, with the use of proper driving tool (Fig. 3), and a soft faced hammer, drive the wear sleeve on the axle housing spindle until it seats evenly against the shoulder of the seal journal of the spindle. A light coating of S.A.E. 10 oil should be applied to the inner surface of the wear sleeve to facilitate assembly of the wear sleeve to axle housing.
8. With a piece of hard wood which will just clear the outer bearing cup, or a brass drift, carefully drive the inner bearing cone and inner seal out of the wheel hub.
9. Clean all the old grease or axle lubricant out of the wheel hub.
10. Inspect the bearing races and rollers for pitting, galling, and erratic wear patterns. Inspect the rollers for end wear (Fig. 7).
11. If the bearing cups are to be replaced, drive them out with a drift. Install the new cups with the tool shown in Fig. 8 or press them in.
12. Check for proper seating of the new bearing cups by trying to insert a 0.0015 inch feeler gauge between the cup and the wheel hub.
13. Pack each bearing cone and roller assembly with a bearing packer tool.

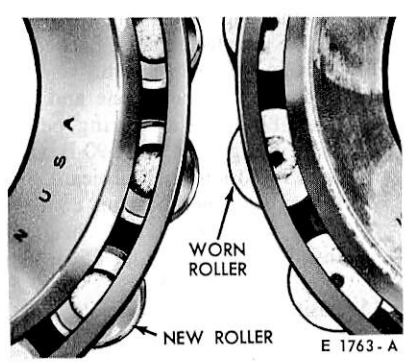

FIG. 7 Roller Bearing End Wear

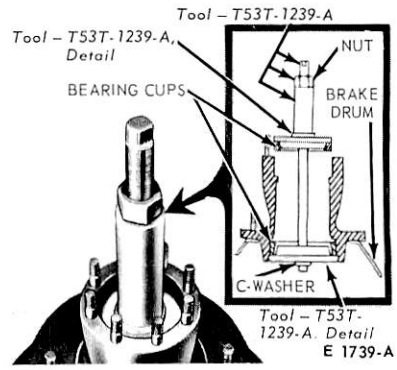

FIG. 8 Installing Bearing Cup

14. Place the inner bearing cone and roller assembly in the wheel hub, and then install a new hub inner seal.
15. Apply a light film of CIAZ-19590-B (ESA-MIC75-B) to the axle spindle; then position a seal protector tool over the axle spindle threads.
16. Position the wheel assembly at the axle housing. Carefully slide the wheel assembly **straight (to avoid seal damage) onto the axle housing spindle. Then, remove the seal protector from the axle spindle.**
17. Install the outer wheel bearing and start the bearing adjuster nut. Remove the wheel jack.
18. **11000-17500 lb. Single Rear Axles and 30000 lb. Tandem Rear Axles:** Torque the adjusting nut to 140 ft-lbs while rotating the wheel to seat the bearings. Back off (loosen) the adjusting nut 1/2 turn; then, torque the adjusting nut again to 50 ft-lbs while rotating the wheel. Back off (loosen) the adjusting nut 1/3 turn. Install the lock washer. Back off the adjusting nut, if necessary to align the lock washer hole with the dowel pin. Install the lock nut and tighten to 125 ft-lbs. The wheel assembly must rotate freely and with an end play of 0.001 to 0.010 inch. **Do not preload the bearings.**

All Other Single and tandem Rear Axles: Torque the adjusting nut to 185 ft-lbs while rotating the wheel to seat the bearings. Back off (loosen) the adjusting nut 1/2 turn; then, torque the adjusting nut again to 50 ft-lbs while rotating the wheel. Back off (loosen) the adjusting nut 1/6 turn.

19. Install a new lock washer and select a tab which is centered on one of the adjusting nut flats.

Remove the lock washer and bend this tab approximately 45 degrees such that the final bend will fit flush on the nut. Reinstall the lock washer. Install the lock nut and torque it to 125 ft-lbs (Fig. 9). With the lock nut at proper torque, the wheel assembly must rotate

freely and with an end play of 0.001-0.010 inch. Do not preload the bearings. Bend the pre-bent lock washer tab flush against the flat of the adjusting nut. Bend another tab flush on the lock nut. Do not use a chisel or other sharp tool to bend the tabs as metal chips could work into the bearings.

20. Install the axle shaft, a new gasket, lock washers and axle shaft retaining nuts. Torque the nuts to specifications.
21. Adjust the brakes. Then, remove the work stands and lower the vehicle.

MEDIUM, HEAVY AND EXTRA HEAVY VEHICLES (OIL LUBRICATION)

Stemco Seals available as regular production options, provide sealing where oil is used for bearing lubrication. The tools required for Stemco Seal Installation are only available from the Stemco warehouse. Refer to specifications for the tooling required. Fig. 10 illustrates a rear wheel Stemco Seal installation.

Rear Hub Seal Installation

1. Thoroughly clean the axle spindle.
2. If the spindle shoulder is scored or pitted apply a thin coat of Permatex No. 2.
3. Position the axle ring and drive it into position flush with the inner bearing shoulder using the correct tool. Procedures vary with different applications. Refer to the instructions packed with each seal set.
4. Remove all burrs and protrusions from the oil seal area of the wheel hub.
5. Pack the inner bearing cone with CIAZ-19590-B (ESA-MIC75-B) and position it in the bearing cup.
6. Position the oil seal at the mouth of the bore and drive it squarely into position using the correct tool. The seal must be evenly bottomed.
7. Take special care not to damage the oil seal while installing the wheel.
8. Fill the wheel cavity with oil before installing the outer bearing.
9. Pack the outer bearing with M1C75-B and install it and then adjust the bearings as outlined in step 18, under 500-900 series.
10. Inspect axle shaft gasket mating surfaces for nicks, burrs, and dirt; then install the axle shaft.
11. Check the rear axle lube level and add oil if required.

DESCRIPTION

Hydraulically operated service brakes are standard equipment on all 100 through 800 Series and on some 900 Series trucks.

Automatic brake shoe adjusters are used on all 100 thru 900 Series trucks with hydraulic brakes.

A dual-master cylinder brake system (Figs. 1 through 4) is used as standard equipment on F-100 through F-350, E-100 through E-300, Bronco, and P-350-400 vehicles. The dual master cylinder is also used on F-500, L-900, LN-600-750, F-6000-7000, LN-6000-7000, C-6000-7000 and B-500-750 Series vehicles equipped with split hydraulic brakes.

Front Disc Brakes are used on F-100 through F-350 4 x 2 trucks.

The standard hydraulic brake system on some vehicles may be assisted by a vacuum booster installed as either standard or optional equipment. Service information on the vacuum booster units is given in Parts 12-50, 12-52, 12-53, 12-54, and 12-60.

The dual, master cylinder contains a double hydraulic cylinder with two fluid reservoirs, two hydraulic pistons (a primary and secondary) and two residual check valves, located in the outlet ports (Fig. 5).

On all 100 through 400 Series Vehicles, the master cylinder front (secondary) outlet port is connected to the rear (secondary) hydraulic circuit and the rear (primary) brake outlet port (nearest the dash panel) is connected to the primary (front) hydraulic circuit.

On all 100 through 400 Series vehicles, the dual master cylinder primary (rear) piston actuates the front wheel brakes. The secondary (front) piston actuates the rear wheel brakes.

The master cylinder primary and secondary pistons function together.

On 500-900 Series trucks with a split hydraulic system, each of the two lines from the dual-master cylinder actuates one brake cylinder at each wheel (front and rear) for vehicles with 15 by 3-inch front brakes. On vehicles with 14 by 2 1/2-inch front duo-servo brakes, the single brake cylinders in both front wheels are actuated by one line that also operates one cylinder at each rear wheel. The line from the other master cylinder outlet port actuates the remaining brake wheel cylinder at each rear wheel.

Brake lines (tubes) are connected from the brake master cylinder primary and secondary system outlet ports to the pressure differential valve assembly (Figs. 5 and 6). The electrical brake warning switch, and the brake lines (tubes) leading from the differential valve assembly to the front and rear wheel brake cylinders are also shown in Figs. 6 and 7.

SINGLE MASTER CYLINDER BRAKE SYSTEM—500-900 SERIES

The standard hydraulic brake system C-Series models is equipped with a single master cylinder and internal expanding shoe drum brakes at all wheels. On all models except P-500, the drum brakes are self adjusting.

The standard hydraulic brake system on some trucks is assisted by a vacuum booster which may be installed as either standard or optional equipment.

DRUM BRAKES

All Ford truck models equipped with hydraulic brakes have internal expanding shoes, except the F-100 through F-350 series which are equipped with front disc brakes. The different types of brake assemblies vary in the way that the shoes are anchored, in the number of wheel cylinders used at each wheel, and in the number of pistons in the wheel cylinder.

In the single anchor type, both brake shoes are mounted to the same anchor and are actuated by one wheel cylinder. In the duo-servo, single anchor brake, the wheel cylinder has two pistons. One piston exerts force against the upper end of the primary shoe; the other piston exerts force against the upper end of the secondary shoe (Figs. 7 and 8).

In the double anchor type, each shoe is mounted to a separate anchor. The shoes are actuated by one duo-servo (two piston) cylinder at the upper end.

The front wheels of some trucks are equipped with two cylinders, each having one piston. The piston in one cylinder exerts force against one end of one shoe; the piston in the other cylinder exerts force against the opposite end of the other shoe.

The rear wheels of some vehicles are equipped with two cylinders, each having two pistons (four pistons total). Each of the four pistons exert force against one end of one shoe (Fig. 9).

TESTING

BRAKE SYSTEM PRELIMINARY CHECKS

1. Always check the fluid level in the brake master cylinder reservoir(s) before performing the test procedures. If the fluid level is not within 1/4 inch of the top of the master cylinder reservoirs, add Ford Brake Fluid-Extra Heavy Duty-Part Number C6AZ-19542-A (ESA-M6C25-A) for all brake applications.**The extra heavy duty brake fluid is colored blue for identification purposes. Do not mix low temperature brake fluids with the specified brake fluid.**

Push the brake pedal down as far as it will go. If the pedal travels more than halfway between the released position and the floor, adjust the brakes. If the vehicle is equipped with automatic brake adjusters, several sharp brake applications while backing up may be necessary to adjust the brakes.

Road test the vehicle and apply the brakes at a speed of about 20 mph to see if the vehicle stops evenly. If not, the brakes should be adjusted. Perform the road test only when the brakes will apply and the vehicle can be safely stopped.

DUAL BRAKE WARNING LIGHT SYSTEM TESTS

1. Turn the ignition switch to the ACC or ON position. If the light on the brake warning lamp remains on, the condition may be caused by a shorted or broken switch, grounded switch wires or the differential pressure valve is not centered. Centralize the differential pressure valve as outlined under Hydraulic System Bleeding and Centralizing of the Differential Valve in this Section of the manual. If the warning light remains on, check the switch connector and wire for a grounded condition and repair or replace the wire assembly. If the condition of the wire is good, replace the brake warning lamp switch.
2. Turn the ignition switch to the start position. If the brake warning lamp does not light, check the light and wiring and replace or repair wiring as necessary.

When both brake systems are functioning normally, the equal pressure at the pressure differential valve during brake pedal application keeps the valve centered. The brake warning light will be on only when the ignition key is in the **START** position.

3. If the brake warning lamp does not light when a pressure differential condition exists in the brake system, the warning lamp may be burned out, the warning lamp switch is inoperative or the switch to lamp wiring has an open circuit. Check the bulb and replace it, if required. Check the switch to lamp wires for an open circuit and repair or replace them, if required. If the warning lamp still does not light, replace the switch.

POWER BRAKE FUNCTION TEST

With the engine stopped, eliminate all vacuum from the system by pumping the brake pedal several times. Then push the pedal down as far as it will go, and note the effort required to hold it in this position. If the pedal gradually moves downward under this pressure, the hydraulic system is leaking and should be checked by a hydraulic pressure test.

With the brake pedal still pushed down, start the engine. If the vacuum system is operating properly, the pedal will move downward. If the pedal position does not change, the vacuum system is not operating properly and should be checked by a vacuum test.

FRAME-MOUNTED VACUUM BOOSTER CHECK VALVE TEST

Disconnect the line from the bottom of the vacuum check valve, and connect a vacuum gauge to the valve. Start the engine, run it at idle speed, and check the reading on the vacuum gauge.

The gauge should register 17-19 inches with standard transmission and 14-15 inches in Drive range if equipped with an automatic transmission. Stop the engine and note the rate of vacuum drop. If the vacuum drops more than one inch in 15 seconds, the check valve is leaking. If the vacuum reading does not reach 18, or is unsteady, an engine tune-up is necessary.

Remove the gauge and reconnect the vacuum line to the check valve.

VACUUM BOOSTER TEST—DIAPHRAGM TYPE

This procedure can be used to test all diaphragm boosters which are equipped with a pipe thread outlet on the atmosphere portion of the diaphragm chamber.

Remove the pipe plug from the rear half of the booster chamber, and install a vacuum gauge. Start the engine and run it at idle speed. The gauge should register 18-21 inches of vacuum.

1. With the engine running, depress the brake pedal with enough pressure to show a zero reading on the vacuum gauge. Hold the pedal in the applied position for one minute. Any downward movement of the pedal during this time indicates a brake fluid leak. Any kickback (upward movement) of the pedal indicates brake fluid is leaking past the hydraulic piston check valve.
2. **With the engine running, push down on the brake pedal with sufficient pressure to show a zero reading on the vacuum gauge. Hold the pedal down, and shut the engine off. Maintain pedal position for one minute. A kickback of the pedal indicates a vacuum leak in the vacuum check valve, in the vacuum line connections, or in the booster.**

ADJUSTMENTS

AIR CHECK BOOSTER PUSH ROD ADJUSTMENT—MIDLAND ROSS BOOSTER (DASH-MOUNTED)

Whenever the master cylinder or booster has been repaired or replaced, the brake system must be checked for proper return flow of hydraulic brake fluid from the wheel cylinders to the reservoir of the master cylinder. This check will assure that the brake booster to master cylinder push rod is properly adjusted to allow the master cylinder compensating valve to open when the brake pedal is in the fully released position.

The air check is made after the brake booster and master cylinder has been installed and before the master cylinder hydraulic line connection is made and the reservoir is filled with brake fluid.

1. Connect the brake vacuum line to the vacuum booster, if required. Start the engine.
2. Carefully position the nozzle of an air hose to the master cylinder discharge port. Place a hand over the master cylinder reservoir and apply air pressure through the air hose nozzle.

Be careful not to allow dirt to enter into the system.

If free passage air pressure is felt on the hand located over the master cylinder reservoir, the brake booster push rod is properly adjusted.

If no air pressure is felt on the hand located over the reservoir, the master cylinder must be removed and the push rod length shortened. To shorten the push rod length, turn the acorn-type screw on the brake booster push rod inward, one turn at a time, until the air check shows the brake master cylinder compensating valve is open.

BRAKE PEDAL ADJUSTMENT

On dual-brake master cylinder or brake mounted vacuum booster equipped vehicles, the brake systems are designed to permit full stroke of the master cylinder when the brake pedal is fully depressed. A brake pedal clearance adjustment is not required.

In order to release the brakes, fluid in a hydraulic brake system must flow back to the master cylinder when pedal pressure is released. A port is provided in the master cylinder to allow this flow, but the piston must move back far enough to expose the return port. To be sure that this will always happen, free-travel is built into the pedal linkage on standard and on frame-mounted booster systems. This free-travel prevents the piston from becoming trapped in a partially released position. Pedal free travel is not always perceptible in dash-mounted booster systems, however, because the operating clearance for the piston is adjusted at the booster push-rod, rather than the pedal linkage. (Refer to Parts 12-50, 12-52 and 12-58 for instructions on dash-mounted booster push rod adjustments).

FRONT DISC BRAKES F-250 AND F-350

The front disc brake assembly is designed so that it is inherently self-adjusting. Refer to Part 12-24.

HYDRAULIC SYSTEM BLEEDING

When any part of the hydraulic system has been disconnected for repair or replacement, air may get into the lines and cause spongy pedal action. This requires the bleeding of the hydraulic system after it has been properly connected to be sure all air is expelled from the brake cylinders and lines. The hydraulic system can be bled manually or with pressure bleeding equipment.

When bleeding the brake system, bleed one brake cylinder at a time, beginning at the cylinder with the longest hydraulic line first. If the brake assembly is equipped with two cylinders, always bleed the upper cylinder first. Keep the master cylinder reservoir filled with the specified C6AZ-19542-A extra heavy duty brake fluid during the bleeding operation. Never use brake fluid which has been drained from the hydraulic system.

The procedure for bleeding the single master cylinder on a C-Series truck is presented separately from the standard hydraulic system bleeding procedures.

If the hydraulic system is equipped with a vacuum booster, bleed the hydraulic section of the booster before bleeding the rest of the system. On vehicles equipped with a frame-mounted booster and split hydraulic brake system, bleed the two booster slave cylinders first then again after bleeding all the wheel cylinders. The bleeding operation must be done with the engine off and with no vacuum in the system. If the brake pedal is still spongy after the first bleeding, repeat the bleeding procedure.

To bleed the hydraulic section of a vacuum booster, follow steps 1 through 4 of the manual bleeding procedure, attaching the drain tube to the bleeder screw at the end plate of the booster (or the bleeder screw nearest the power chamber). Repeat this procedure at the other bleeder screw if the booster is so equipped.

On dual-brake system hydraulic master cylinder equipped vehicles, it will be necessary to centralize the pressure differential valve after a brake hydraulic system malfunction has been corrected and the hydraulic system has been bled. Before any attempt is made to bleed the split hydraulic brake system on 500-950 Series trucks, remove the brake light warning switch from the pressure differential valve. Failure to remove the switch from the valve could result in possible damage to the switch assembly.

It is necessary to depress the bleeder button on the metering valve when bleeding the front brakes. This is to allow the brake fluid to reach the caliper assemblies. This operation is particularly important if pressure bleeding equipment is being used.

MANUAL BLEEDING—CONVENTIONAL, SINGLE-BRAKE SYSTEM HYDRAULIC MASTER CYLINDER

1. Attach a rubber drain tube to the bleeder screw of the brake wheel cylinder. The end of the tube should fit snugly around the bleeder screw.
2. Submerge the free end of the tube in a container partially filled with clean brake fluid. Loosen the bleeder screw.
3. Push the brake pedal down slowly by hand, allowing it to return slowly to the fully-released position. Repeat this operation until air bubbles cease to appear at the submerged end of the tube.
4. When the fluid is completely free of air bubbles, close the bleeder screw and remove the drain tube.
5. Repeat this procedure at each brake cylinder. Refill the master cylinder reservoir after each brake cylinder is bled **with C6AZ-19542-A extra heavy duty brake fluid and** when the bleeding operation is completed.

MANUAL BLEEDING—DUAL-BRAKE SYSTEM HYDRAULIC MASTER CYLINDER

The primary and secondary

hydraulic brake systems are individual systems and are bled separately. Bleed the longest line first on the individual system being serviced. **During the complete bleeding operation, DO NOT allow the reservoir to run dry. Keep the master cylinder reservoirs filled with the specified brake fluid. Never use brake fluid that has been drained from the hydraulic system.**

1. Remove the brake light warning light switch from the pressure differential valve (Fig. 7) on 500-900 Series trucks.
2. Bleed the master cylinder at the outlet port side of the system being serviced.

On a master cylinder without bleed screws, loosen the master cylinder to hydraulic line nut. Operate the brake pedal slowly until the brake fluid at the outlet connection is free of bubbles, then tighten the tube nut to the specified torque. **Do not use the secondary piston stop screw located on the bottom of the master cylinder to bleed the brake system. Loosening or removing this screw could result in damage to the secondary piston or stop screw.** Operate the brake pedal slowly until the brake fluid at the outlet connection is free of air bubbles, then tighten the bleed screw.

3. Position a suitable 3/8 inch box wrench on the bleeder fitting on the brake wheel cylinder. Attach a rubber drain tube to the bleeder fitting. The end of the tube should fit snugly around the bleeder fitting.
4. Submerge the free end of the tube in a container partially filled with clean brake fluid, and loosen the bleeder fitting approximately 3/4 turn.
5. Push the brake pedal down slowly thru its full travel. Close the bleeder fitting, then return the pedal to the fully-released position. Repeat this operation until air bubbles cease to appear at the submerged end of the bleeder tube.
6. When the fluid is completely free of air bubbles, close the bleeder fitting and remove the bleeder tube.
7. Repeat this procedure at the brake wheel cylinder on the opposite side. Refill the master cylinder reservoir after each wheel cylinder is bled.

When the bleeding operation is complete, the master cylinder fluid level should be filled to within 1/4 inch from the top of the reservoirs.

8. Centralize the pressure differential valve. Refer to the Centralizing of the Pressure Differential Valve procedures in this Section.
9. Install the brake warning light switch on the pressure differential valve on 500-900 Series trucks.

PRESSURE BLEEDING—CONVENTIONAL SINGLE-BRAKE SYSTEM HYDRAULIC MASTER CYLINDER

Be sure that the tank is clean and there is enough of the specified brake fluid (C6AZ-19542-A extra heavy duty) in the bleeder tank to complete the bleeding operation and that the tank is charged with 10-30 pounds of air pressure. Never exceed 50 pounds pressure.

On a C-Series truck with a single master cylinder, the master cylinder can only be bled manually. Therefore, bleed the entire hydraulic system first before bleeding the master cylinder.

1. On a L-, LN-, or LT-Series truck, clean all dirt from around the filler hole on the top of the master cylinder reservoir, and attach the bleeder tank hose to the filler hole.

On a C-Series truck with a single master cylinder, disconnect the line from the bottom of the master cylinder and connect the line to the pressure bleeder tank hose. Install a 5/16 inch Weatherhead plug into the bottom of the master cylinder.

2. Attach a rubber drain tube to the bleeder screw of the brake cylinder. The end of the tube should fit snugly around the bleed screw.
3. Submerge the free end of the tube in a container partially filled with clean brake fluid and then loosen the bleeder screw.
4. Open the valve on the bleeder tank to admit pressurized brake fluid to the master cylinder reservoir (or line).
5. When air bubbles cease to appear in the fluid at the submerged end of the drain tube, close the bleeder screw and remove the tube.
6. Repeat this procedure at each brake cylinder.
7. When the bleeding operation is completed, close the bleeder tank valve and remove the tank hose from the filler hole.

On a C-Series truck with a single master cylinder, remove the line from the tank hose and connect it to the master cylinder.

8. On all vehicles, refill the master cylinder reservoir to within 1/4 inch from the top of the filler neck.

C-SERIES TRUCK SINGLE MASTER CYLINDER BLEEDING

1. Loosen the fittings at the bottom of the master cylinder, approximately one turn.
2. Wrap a shop cloth, or a piece of clean waste material, around the tubing below the fitting to absorb expended brake fluid.
3. Push the brake pedal down slowly by hand to the floor of the cab. This will force air which may be trapped in the master cylinder to escape at the fitting.
4. Hold the pedal down and tighten the fitting. Release the brake pedal. **Do not release the brake pedal until the fitting is tightened as additional air will be introduced into the master cylinder.**
5. Repeat this procedure until air ceases to escape at the fitting and a firm pedal is obtained.

PRESSURE BLEEDING—DUAL BRAKE SYSTEM HYDRAULIC MASTER CYLINDER

Bleed the longest lines first. The bleeder tank should contain enough of the specified brake fluid (C6AZ-19542-A extra heavy duty) to complete the bleeding operation. The tank should be charged with approximately 10 to 30 pounds of air pressure. Never exceed 50 pounds pressure. **Never use brake fluid that has been drained from the hydraulic system.**

1. Remove the brake warning light switch from the pressure differential valve on 500-900 Series trucks (Fig. 7).
2. Clean all dirt from the master cylinder reservoir cover.
3. Remove the master cylinder reservoir cover and rubber gasket, and fill the master cylinder reservoir with the specified brake fluid. Install the pressure bleeder adapter tool to the master cylinder, and attach the bleeder tank hose to the fitting on the adapter.

Master cylinder pressure bleeder adapter tools can be obtained from the various manufacturers of pressure bleeding equipment. Follow the instructions of the manufacturer when installing the adapter.

4. Position a 3/8 inch box wrench on the bleeder fitting on the right rear brake wheel cylinder. Attach a bleeder tube to the bleeder fitting. **The end of the tube should fit snugly around the bleeder fitting.**
5. Open the valve on the bleeder tank to admit pressurized brake fluid to the master cylinder reservoir.
6. Submerge the free end of the tube in a container partially filled with clean brake fluid, and loosen the bleeder fitting.
7. When air bubbles cease to appear in the fluid at the submerged end of the bleeder tube, close the bleeder fitting and remove the tube.

9. When the bleeding operation is completed, close the bleeder tank valve and remove the tank hose from the adapter fitting.
10. **Remove the Pressure Bleeder Adapter Tool. Fill the master cylinder reservoirs to within 1/4 inch from the top. Install the master cylinder cover and gasket.**
11. **Centralize the pressure differential valve.**
12. Install the brake warning light switch on the pressure differential valve on 500-900 Series trucks.

CENTRALIZING THE PRESSURE DIFFERENTIAL VALVE

F-100-350, E-100-300, P-350-400 AND BRONCO

After any repair or bleeding of the primary (front brake) or secondary (rear brake) system, the dual-brake warning light will usually continue to be illuminated due to the pressure differential valve remaining in the off center position.

To centralize the pressure differential valve and turn off the warning light after a repair operation:

1. Turn the ignition switch to the ACC or ON position.
2. Check the fluid level in the master cylinder reservoirs and fill them to within 1/4 inch of the top with the specified brake fluid, if necessary.
3. Depress the brake pedal and the piston will center itself causing the brake warning light to go out.
4. Turn the ignition switch to the OFF position.
5. Before driving the vehicle, check operation of the brakes and be sure that a firm pedal is obtained.

500-900 SERIES TRUCKS WITH SPLIT HYDRAULIC BRAKES

The pressure differential valve used with the split hydraulic brake system has a self centering spring. Use the following procedure to reset the valve:

1. Remove the switch connector wire.
2. Remove the threaded hex-shaped electrical switch body from the center of the valve. This allows the valve centering springs to re-position the valve.
3. Install the electrical switch and connect the wire.
4. Apply the brakes a few times and check the operation of the warning light. The light should go on with the ignition switch in the START position only.

HYDRAULIC LINE REPAIR

Steel tubing is used in the hydraulic lines between the master cylinder and the front brake tube connector (Fig. 10), and between the rear brake tube connector (Fig. 11) and the rear brake cylinders. Flexible hoses connect the brake tube to the front brake cylinders and to the rear brake tube connector.

When replacing hydraulic brake tubing, hoses, or connectors, tighten all connections securely. After replacement, bleed the brake system at the wheel cylinders and at the booster, if so equipped.

BRAKE TUBE

If a section of the brake tube becomes damaged, the entire section should be replaced with tubing of the same type, size, shape, and length. **Copper tubing should not be used in the hydraulic system.** When bending brake tubing to fit the frame or rear-axle contours, be careful not to kink or crack the tube.

All brake tubing should be double flared to provide good leak-proof connections. Always clean the inside of a new brake tube with clean isopropyl alcohol.

Flaring a Line (Split-Die Type)

Refer to Figs. 12 and 13

1. Cut off and straighten the required length of line (A line cutting tool will simplify obtaining a clean and square cut).
2. Square off the ends of the line with a file and chamfer the end of the line to be flared.
3. Select the split die for the line being used and insert the die into the tapered hole in the body.
4. Push the tube through the die until the line is flush with the face of the die. Lock the line inn this position by tightening the wing nut securely.
5. The punches are marked Op. 1 and Op. 2. Slide the first operation punch into the hole in the center of the body and tighten the screw well home to form the single flare.
6. Release the screw and replace the first operation punch with the second operation punch and tighten the screw to form the double flare.
7. Release the screw, wing nut, punch and dies.
8. Remove the line and inspect the flare for cracks or poor flare form. If any doubt exists about the flare it should be cut off and the process repeated.

The finished flare must be square with the line, free from any cracks and have a smooth mating surface to ensure a leakproof connection.

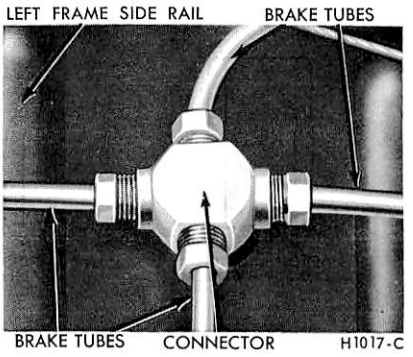

FIG. 10 Front Brake Tube Connector—Typical

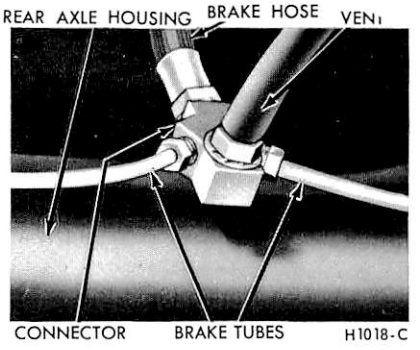

FIG. 11 Rear Brake Tube Connector

Flaring a Line (Flaring-Bar Type)

Refer to Figs. 12 and 14.

1. Cut off and straighten the required length of line. (A line cutting tool will simplify obtaining a clean and square cut.)
2. Square off the ends of the line with a file and chamfer the end of the line to be flared.
3. Insert the line through its appropriate ribbed hole in the bar assembly until the end of the line protrudes approximately the thickness of the respective adaptor above the bar, or flush with the bar, depending on the tool used.
4. Fit the adaptor on to the line and slide the bar into the yoke. Lock the bar in position with the line beneath the yoke screw.
5. Form the single flare by screwing the yoke screw well home.
6. Release the screw and remove the adaptor.
7. Form the double flare by screwing down the yoke screw again, with second adaptor fitted, depending on the tool used.
8. Release the screw, bar and flared

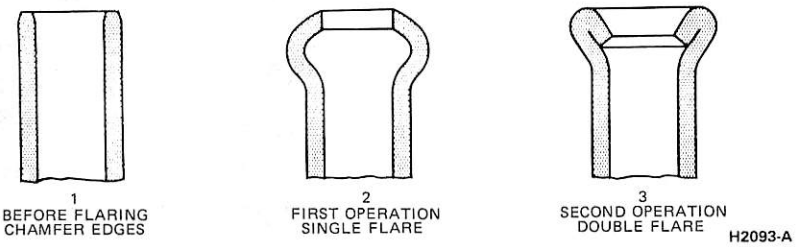

FIG. 12 Line Flaring Sequence

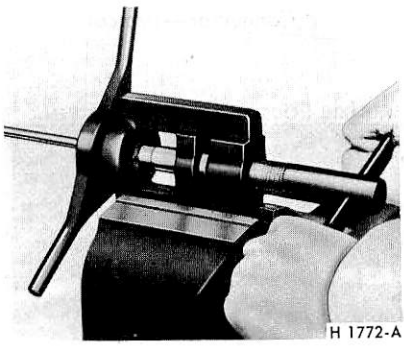

FIG. 13 Line Flaring (Split Die Type)

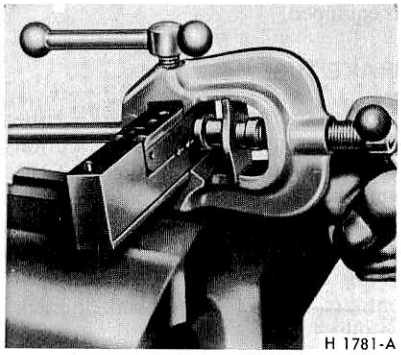

FIG. 14 Line Flaring (Flaring Bar Type)

line. Inspect the flare for cracks or poor flare form and if any doubt exists about the flare, it should be cut off and the process repeated.

8. Repeat steps 3 through 6 at the opposite wheel cylinder of the system being bled.

BRAKE HOSE

A flexible brake hose should be replaced if it shows signs of softening, cracking, or other damage.

When installing a new brake hose, position the hose to avoid contact with other truck parts.

REMOVAL AND INSTALLATION

BRAKE DRUM REMOVAL AND INSTALLATION THROUGH 1000 SERIES

The service procedures covered here apply to both hydraulic and air brakes. Since the F-100 through 350, E-100 through 300, Bronco or the P-350, 400 (front and rear) and the 4-wheel drive front brake drum procedures apply to hydraulic brakes only, they are covered in the Removal and Installation Section of Part 12-02.

FRONT BRAKE DRUM

1. Raise the truck until the wheel and tire clear the floor and remove the wheel and tire from the hub. Back off the brake shoe adjusting screw so that the shoes do not contact the brake drum. Remove the grease cap and the gasket (if so equipped) from the hub.
2. With 4,000 through 7,000 lb. and 18,000 lb. front axles, remove the cotter pin, adjusting nut and flat washer from the spindle.

On trucks with a 9,000, 11,000 or 15,000 lb. axle, remove the lock nut, the dimpled washer, the locking ring and the adjusting nut and pin assembly.

3. Remove the outer bearing cone and roller. Pull the hub and drum assembly off the wheel spindle.
4. Remove the front wheel to hub retaining nuts or rim and tire attaching nuts. Remove the wheel or rim and tire from the hub and drum.
5. Remove the brake drum retainers and attaching bolts, screws, or bolts and nuts.
6. Remove the brake drum from the hub.
7. Check the drum for damage or wear, and repair or replace as necessary. If a new drum is to be installed, be sure to remove the protective coating with a suitable degreaser.

New grease retainer seals should be installed whenever a wheel and hub is removed.

8. Place the brake drum to the hub and install the retainers and retaining bolts, screws, or bolts and nuts.
9. Install the hub and drum on the wheel spindle. **Keep the hub centered on the spindle to prevent damage to the grease retainer or the spindle threads.**
10. With 4,000 through 7,000 lb. and 18,000 lb. front axles, install the outer bearing cone and roller and the flat washer on the spindle, then install the adjusting nut. With front axles of 9,000 lbs., 11,000 or 15,000 lbs. capacity, install the outer bearing cone and roller and the bearing adjusting nut and pin assembly.
11. Install the wheel and tire on the hub, then install the clamps (if applicable) and the wheel stud nuts.
12. Torque the adjusting nut to specifications while rotating the wheel. Refer to Group 11 for the wheel bearing adjustment procedure.

Install the dimpled washer with the dimple indexed in one of the holes in the adjusting nut. Install the lock nut and torque to specifications. Bend the dimpled washer over a flat of the lock nut.

13. Install the gasket (if so equipped) and the grease cap, and torque the wheel stud nuts to specifications. Install the hub cap if so equipped, and adjust the brakes.

REAR BRAKE DRUM

1. Raise the truck and install safety stands.
2. Remove the wheel and tire as an assembly. Then back off the rear brake shoe adjustment.
3. Remove the rear axle shaft retaining nuts, adapters, axle shaft, and grease seal.
4. Remove the wheel bearing locknut, lock washer, and adjusting nut.
5. Remove the hub and drum from the axle.
6. Remove the brake drum to hub retaining screws, bolts, or bolts and nuts. Then remove the brake drum from the hub.
7. Check the drum for damage or wear, and repair or replace as necessary. Brake drums must not be machined to a braking surface diameter greater than the maximum diameter shown on the drum. If a new drum is to be installed, be sure to remove the protective coating with a suitable degreaser.

New grease retainer seals should be installed whenever a wheel and hub is removed.

8. Position the brake drum to the hub and install the attaching screws, bolts, or bolts and nuts.
9. Position the hub and drum as an assembly on the axle and start the adjusting nut.
10. Adjust the wheel bearing nut and then install the wheel bearing lock washer and lock nut.
11. Install a new rear axle oil seal, axle shaft and gasket, stud adapters, and attaching nuts.
12. Install the wheel and tire as an assembly.
13. Adjust the brake shoes and then remove the safety stands and lower the truck.

OVERHAUL

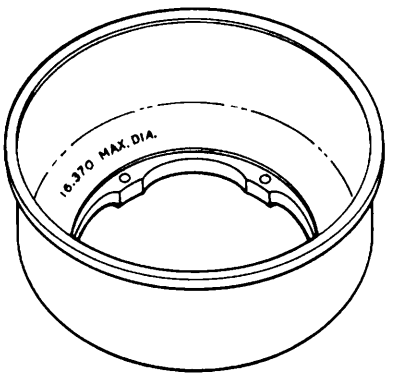
BRAKE DRUM REFINISHING

Minor scores on a brake drum can be removed with fine emery cloth, provided the emery is thoroughly cleaned off the drum after the operation.

A badly scored, rough, or out-of-round drum should be ground or turned on a drum lathe. Do not remove any more material from the drum than is necessary to provide a smooth surface for the brake shoe contact. **Brake drum maximum braking surface diameter is shown on each brake drum (Fig. 14). Brake drums which exceed the maximum braking surface diameter shown on the brake drum, either through wear or refinishing, must be replaced. The maximum braking surface diameter specification, which is shown on each brake drum, allows for a 0.060 inch machining cut over the original nominal drum diameter plus 0.030 inch additional wear before reaching the drum-discard diameter.**

BRAKE SHOE AND BAND RELINING

1. Remove the rivets and remove the old lining.
2. Clean the shoe or band thoroughly with cleaning fluid, especially the rim surface. Wipe the shoe or band dry and remove all burrs or rough spots from the shoe.
3. On service brake, check the inside diameter of the brake drum.
4. Position the new lining on the shoe or band and install new rivets, beginning with the rivet holes near the center of the shoe. On some vehicles, the primary lining is shorter than the secondary lining. If this condition exists, position the shorter (primary) lining to line up with the heel end of the shoe. **Do not let brake fluid, oil or grease touch the brake lining. If a brake lining kit is used to replace the worn linings, install all the parts supplied in the kit.**
5. Check the clearance between the lining and shoe rim. The lining must seat snugly against the rim with not more than 0.005 inch separation midway between any two rivets. If only the linings are replaced on duo-servo single anchor brakes with fixed anchor pins, the brake linings must be cam ground 0.010 inch at the ends after the linings are riveted to the brake shoe.



H1834-A

FIG. 15 Brake Drum Maximum Braking Surface Diameter Marking Location—Typical Medium—Heavy Truck Shown

FRONT DISC BRAKES

1. Remove the shoe and linings as outlined in Part 12-24.
2. Make three thickness measurements with a micrometer across the middle section of the shoe and lining. Take one reading at each side and one in the center. If the assembly has worn to a thickness of 0.210 inch (Shoe and lining together) at any one of the three measuring locations, or if the lining shows evidence of brake fluid or oil contamination that is causing a brake pull, replace all (4) shoe and lining assemblies.
3. Check caliper to spindle attaching bolt torque (F-250-350, above 6200 G.V.W.). Torque them to specification if required.
4. To check rotor runout, first eliminate the wheel bearing end play by tightening the adjusting nut. After tightening the nut, check to see that the rotor can still be rotated.
5. Clamp a dial indicator to the spindle so that the stylus contacts the rotor at a point approximately 1 inch from the outer edge. Rotate the rotor and take an indicator reading. If the reading exceeds 0.010 inch total lateral runout within a six inch radius on the indicator, replace or resurface the disc brake rotor. **The following requirements must be met when resurfacing disc brake rotors (Fig. 15).**

Rotunda Disc Brake Refinishing Lathe, Tool FRE-1466-B should be used to refinish the disc brake rotors. The step-by-step resurfacing procedure provided with the tool must be adhered to.

A maximum of 0.020 inch material may be machined equally off each surface (A and B) (Fig. 16). If rotor thickness falls below the minimum shown on each rotor, it must be replaced.

The finished braking surfaces of the rotor must be flat and parallel within 0.001 inch; lateral runout must not exceed 0.003 inch total indicator reading within a six inch radius, and the surface finish of the braking surfaces are to be 15-80 micro inches.

When the runout check is finished, be sure to adjust the bearings as outlined in Part 11-10, in order to prevent bearing failure.

6. Check the rotor for scoring. Minor scores can be removed with a fine emery cloth. If the rotor is excessively scored, refinish it as outlined in Step 5 or replace the rotor if required.
7. Visually check the caliper. If it is cracked or if any leakage is evident, it should be replaced. Any leakage around the dust boot indicates the need for removal and disassembly.
8. Check brake hoses for signs of cracking, leaks, or abrasion. Replace if necessary.

BRAKE CYLINDER

1. Clean all brake cylinder parts in clean isopropyl aocohol. Inspect all parts for wear or damage. Check the cylinder bore for rust, scores, or other damage. Be sure that the bleeder screw passage is clean and open. Replace all parts that are worn or damaged.
2. **If dirt is found in any part of the hydraulic system, flush the entire system with clean isopropyl alcohol.**

MASTER CYLINDER

1. Clean all master cylinder parts in clean isopropyl alcohol, and inspect the parts for wear or damage, replacing them as required. **When a master cylinder repair kit is used, install all of the parts supplied in the kit.**
2. Check the ports and vents in the master cylinder to make sure that all are open and free of foreign matter.
3. On a single brake system master cylinder, check to see if the spring valve (riveted to the front end of the piston) is loose or has moved so that the piston ports are open, replace the piston.
4. Inspect the cylinder walls for scores or rust, and recondition them if necessary. Hone the cylinder walls no more than necessary (0.003 inch maximum), either to remove scores and rust, or to obtain a smooth wall surface. Remove any burrs or loose metal that may have resulted from the honing operation, and clean the cylinder with clean isopropyl alcohol.

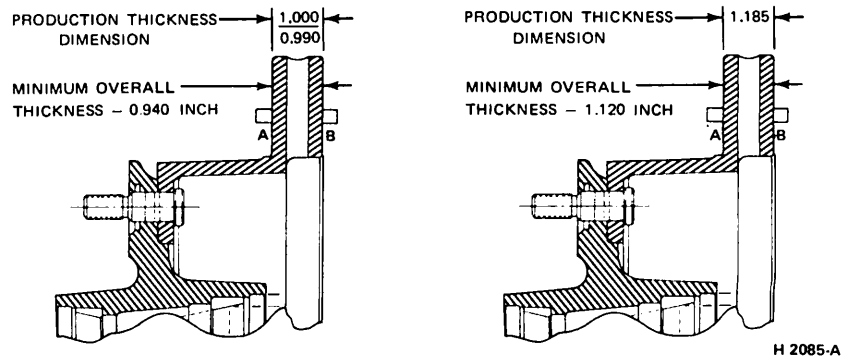


FIG. 16 Disc Brake Rotor Service Limits

BRAKE DRUMS AND LININGS

1. After removing one front wheel and drum and one rear wheel and drum from the vehicle, inspect the drums and brake shoe linings for wear or damage that would affect brake operation. **Do not let brake fluid, oil or grease touch the drum or linings.**
2. A brake shoe should be relined when the lining face is worn to within 1/32 inch of any rivet head, or when the lining has been soaked with brake fluid, oil or grease. If a worn lining is not replaced, the brake drum may become severely damaged. **Always replace the primary and secondary brake shoe lining assemblies on both front or both rear brake assemblies at the same time.**
3. Before relining a brake shoe, inspect the shoe for distortion, cracks, or looseness between the rim and web. If one of these conditions exists, replace the shoe. **Do not attempt to repair a damaged brake shoe.**
4. If the drum and linings are in good condition, install the wheel and drum. **The condition of the drums and linings of the opposite wheel will usually be about the same as that found at the wheel that was removed.**
5. Add enough of the specified brake fluid to the master cylinder reservoir to bring the level to within 1/4 inch of the top of the filler neck.
6. Check to be sure that the parking brake is fully released before making any brake adjustment.
7. Check the front brake anchor pin nut with a wrench (on brake assemblies with an adjustable anchor pin). If the bolt is loose, torque it to 80-100 ft-lbs.

ADJUSTMENTS

SELF ADJUSTING BRAKES—F-100-350, E-100-300, P-350-400 AND BRONCO

The brake shoes are automatically adjusted when the vehicle is driven in reverse and the brakes applied. A manual adjustment is required only after the brake shoes have been relined or replaced. **The manual adjustment is performed while the drums are removed, using the tool and the procedure detailed below.**

When adjusting the rear brake shoes, check the parking brake cables for proper adjustment. Make sure that the equalizer operates freely.

To adjust the brake shoes:

1. Use Rotunda Tool HRE8650, (Fig. 1) and adjust to the inside diameter of the drum braking surface.
2. **Reverse the tool as shown in Fig. 2 and adjust the brake shoes to touch the gauge. The gauge contact points on the shoes (Fig. 2) must be parallel to the vehicle with the center line through the center of the axle. Hold the automatic adjusting lever out of engagement while rotating the adjusting screw, to prevent burring the screw slots. Make sure the adjusting screw rotates freely. If necessary, lubricate the adjusting screw threads with a thin, uniform coating of C1AZ-19590-B grease.**
3. Apply a small quantity of C1AZ-19590-B high temperature grease to the points where the shoes contact the carrier plate, being careful not to get the lubricant on the linings.
4. Install the drums. Install the retaining nuts and tighten securely.
5. Install the wheels on the drums and tighten the mounting nuts to specifications.
6. Complete the adjustment by applying the brakes several *times* while backing the vehicle.
7. After the brake shoes have been properly adjusted, check the operation of the brakes by making several stops while operating in a forward direction.

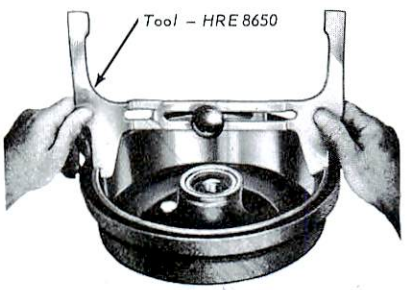

FIG. 1 Measuring Drum

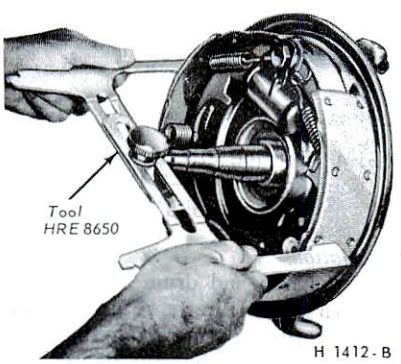

FIG. 2 Measuring Shoes

FRONT BRAKE—P-500

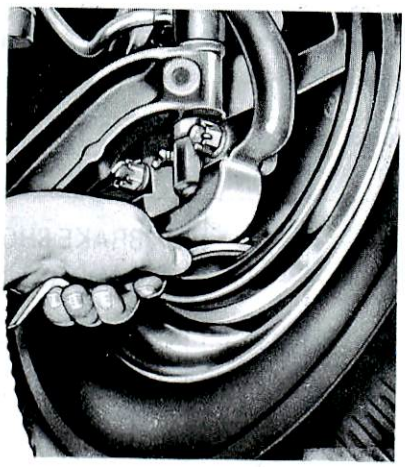
Manual Adjustment

The single anchor brake is adjusted by turning an adjusting screw located between the lower ends of the shoes (Figs. 3, 4 and 5).

1. Raise the vehicle until the wheels clear the floor.
2. Remove the cover from the adjusting hole at the bottom of the brake carrier plate, and turn the adjusting screw inside the hole to expand the brakes shoes until they drag against the brake drum and lock up the drum. Back off the adjusting screw until a slight drag is noted (Fig. 3).
3. When the shoes are against the drum, back off the adjusting screw 10 to 12 notches so that the drum rotates freely without drag. If the drum does not rotate freely, remove the wheel and drum, and then blow out the dust and dirt from the linings. With sand paper, remove all

rust from the points where the shoes contact the carrier plate and apply a light coating of high temperature grease (C1AZ-19590-B). Be careful not to get the lubricant on the linings.

4. Install the wheel and drum, and adjust the shoes. Install the adjusting hole cover on the brake backing plate.
5. Check and adjust the other three brake assemblies.
6. Apply the brakes. If the pedal travels more than halfway down between the released position and the floor, too much clearance exists between the brake shoes and the drums. Repeat steps 2 and 3 above.
7. When all brake shoes have been properly adjusted, lower the vehicle. Road test the vehicle and check the operation of the brakes. Perform the road test only when the brakes will apply and the vehicle can be safely stopped.



H1006-B

FIG. 3 Single Anchor Brake Shoe Adjustment

REMOVAL AND INSTALLATION

BRAKE DRUMS

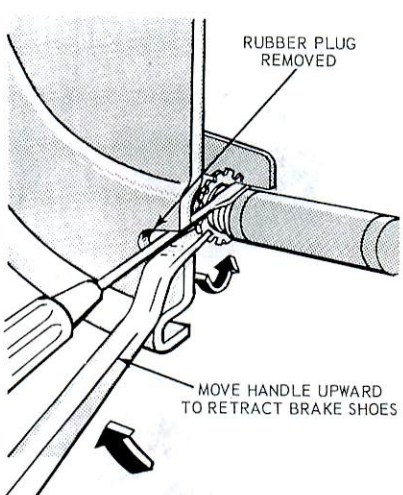
FRONT BRAKE DRUM—E-100-300, AND P-350-400 SERIES

Removal

1. Raise the vehicle so that the wheel is clear of the floor.
2. Remove the wheel cover or hub cap and wheel, bearing dust cap. Remove the cotter pin, nut lock, nut, and washer.
3. Pull the brake drum approximately two inches forward and push back into position. Remove the wheel bearing and withdraw the brake drum.

If the brake drum will not come off, insert a narrow screwdriver through the brake adjusting hole in the carrier plate, and disengage the adjusting lever from the adjusting screw. While thus holding the adjusting lever away from the adjusting screw, back off the adjusting screw with the brake adjusting tool (Fig. 4). **Back off the adjustment only if the drum cannot be removed. Be very careful not to burr, chip, or damage the notches in the adjusting screw; otherwise, the self adjusting mechanism will not function properly.**

If the adjusting screw was backed off, check to make sure that the adjusting lever is still properly seated in the shoe web.



H1590-A

FIG. 4 Backing Off Brake Adjustment—F-100-250, E-100-200, and Bronco

Installation

1. If the hub and drum assembly is being replaced, remove the protective coating from the new drum with carburetor degreaser. Install new bearings and grease retainer. Pack the wheel bearing, install the inner bearing cone and roller assembly in the inner cup, and install the new grease retainer. **Refer to Part 11-10,** If the original drum is being installed, make sure that the grease in the hub is clean and adequate.
2. **Install the drum assembly, outer wheel bearing, washer and *adjusting* nut. Refer to Part 11-10.**
3. Adjust the wheel bearing, install the nut lock and cotter pin, then install the grease cap.
4. Install the wheel and hub cap. If the adjustment was backed off, adjust the brake as outlined under Brake Shoe Adjustment.

REAR BRAKE DRUM—F-100-F-250 (EXCEPT HEAVY DUTY), E-100-200 AND BRONCO

Removal

1. Raise the vehicle so that the wheel is clear of the floor.
2. Remove the hub cap and wheel and tire assembly. Remove the three retaining nuts and remove the brake drum.

If the brake drum will not come off, insert a narrow screwdriver through the brake adjusting hole in the backing plate, and disengage the adjusting lever from the adjusting screw. While thus holding the adjusting lever away from the adjusting screw, back off the adjusting screw with the brake adjusting tool (Fig. 4). **Back off the adjusting screw if the drum cannot be removed. Be very careful not to burr, chip, or damage**

the notches in the adjusting screw; otherwise the self adjusting mechanism will not function properly.

If the adjusting screw was backed off, check to make sure that the adjusting lever is still properly seated in the shoe web.

Installation

1. Remove the protective coating from a new drum with carburetor degreaser.
2. Adjust the brakes as outlined under Brake Shoe Adjustments.
3. Install the drum.
4. Install the three retaining nuts and tighten securely. Install the wheel on the axle shaft flange studs against the drum, and tighten the retaining nuts to specifications.

REAR BRAKE DRUM—F-250 (HEAVY DUTY) 350, E-300, P-350, P-400

Removal

1. Raise the truck and install stands.
2. Remove the wheel and tire as an assembly. Then back off the rear brake shoe adjustment.
3. Remove the rear axle retaining nuts, adapters, axle shaft, and grease seal.
4. Remove the wheel bearing locknut, lock washer, and adjusting nut.
5. Remove the hub and drum from the axle.
6. Remove the brake drum to hub retaining screws, bolts, or bolts and nuts. Then remove the brake drum from the hub.

Installation

1. Check the drum for damage or wear, and repair or replace as necessary. If a new drum is to be installed, be sure to remove the protective coating with a suitable degreaser.

New grease retainer seals should be installed whenever a wheel and hub is removed. Refer to Part 11-11.

2. Position the brake drum to the hub and install the attaching screws, bolts, or bolts and nuts.
3. Position the hub and drum as an assembly on the axle and start the adjusting nut.
4. Adjust the wheel bearing nut and then install the wheel bearing lock washer and locknut. Refer to Part 11-11.
5. Install a new rear axle oil seal, axle shaft and gasket, stud adapters, and attaching nuts.
6. Install the wheel and tire as an assembly.
7. Adjust the brake shoes and then remove the stand and lower the truck.

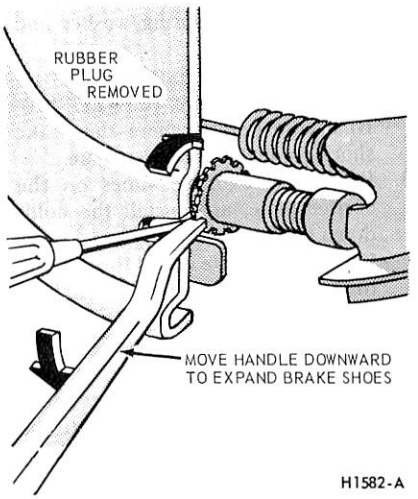


FIG. 5 Expanding Brake Shoes—F-250-350, E-300, and P-350-400

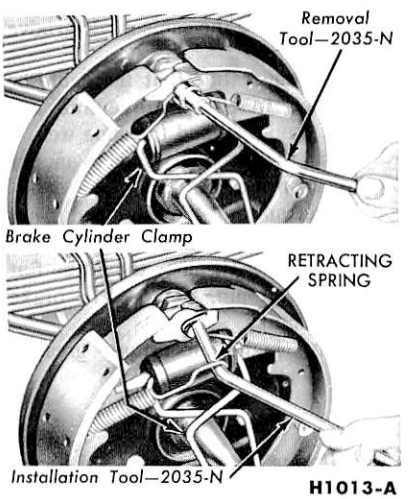

FIG. 6 Spring Replacement—Typical

FRONT BRAKE DRUM—F-100-250 (4 X 4) AND BRONCO

Removal

1. Raise the vehicle and install stands.
2. Back off the brake shoe adjustment. Remove the hub dust cap.

Remove the hub retaining snap ring, and slide the splined driving hub from between the axle shaft and the wheel hub. Remove the driving hub spacer and spring.

3. With Tool T59T-1197-B, remove the lock nut, the nut lock, and the wheel bearing adjusting nut from the steering spindle. Remove the wheel, hub and drum as an assembly. The wheel outer bearing will be forced off the spindle at the same time. Remove the wheel inner bearing cone.

If the vehicle is equipped with a locking type hub refer to Part 11-12.

4. Remove the front wheel to hub retaining nuts. Remove the wheel and tire from the hub and drum.
5. Remove the brake drum retaining bolts and nuts.
6. Remove the brake drum from the hub.

Installation

1. Place the brake drum to the hub and install the retaining bolts and nuts.
2. Install the wheel and tire to the hub and start the retaining nuts.
3. Install the wheel hub and drum assembly on the spindle. Install the driving hub spacer and then the wheel outer bearing cone and the adjusting nut with the dowel outboard.
4. **Rotate the wheel in either direction and, at the same time, tighten the inner locknut to 50 ft-lbs with Tool T59T-1197-A.**
5. Follow the Procedure under Front Wheel Bearing Adjustment in Part 11-12.
6. Slide the driving hub on the axle shaft and install the snap ring.

If the vehicle is equipped with a locking type hub, refer to Part 11-12.

7. Adjust the brake, and then torque the wheel nuts.
8. Install the dust cap.
9. Remove the stands and lower the truck.

BRAKE DRUMS 500 THROUGH 1000 SERIES

Since the brake drum service procedures for these models apply to both hydraulic and air brakes, they are covered under Removal and Installation in Part 12-01.

BRAKE SHOE AND ADJUSTING SCREW

F-100-250, E-100-200 AND BRONCO EXCEPT HEAVY DUTY

Removal

1. With the wheel and drum removed, install a clamp over the ends of the brake cylinder as shown in Fig. 6.
2. Contract the shoes as follows:
   a. Disengage the adjusting lever from the adjusting screw by pulling backward on the adjusting lever (Fig. 7).
   b. Move the outboard side of the adjusting screw upward and back

off the pivot nut as far as it will go.

3. Pull the adjusting lever, cable and automatic adjuster spring down and toward the rear to unhook the pivot hook from the large hole in the secondary shoe web. **Do not attempt to pry the pivot hook out of the hole.**
4. Remove the automatic adjuster spring and adjusting lever.
5. Remove the secondary shoe to anchor spring with the tool shown in Fig. 6. With the same tool, remove the primary shoe to anchor spring and unhook the cable anchor. Remove the anchor pin plate, when so equipped.
6. Remove the cable guide from the secondary shoe (Fig. 7).
7. Remove the shoe hold-down springs, shoes, adjusting screw, pivot nut, and socket. Note the color of each hold-down spring for assembly.
8. On rear brakes, remove the parking brake link and spring. Disconnect the parking brake cable from the parking brake lever.
9. After removing the rear brake secondary shoe, disassemble the parking brake lever from the shoe by removing the retaining clip and spring washer (Fig. 7).

Installation

1. Before installing the rear brake shoes, assemble the parking brake lever to the secondary shoe and secure with the spring washer and retaining clip.
2. Apply a light coating of high temperature grease (C1AZ-19590-B) at the points where the brake shoes contact the carrier plate.
3. Position the brake shoes on the carrier plate, and install the hold-down spring pins, springs, and cups. On the rear brake install the parking brake link, spring and washer. Connect the parking brake cable to the parking brake lever (Fig. 7).
4. Install the anchor pin plate, when so equipped, and place the cable anchor over the anchor pin with the crimped side toward the backing plate.
5. Install the primary shoe to anchor spring with the tool shown in Fig. 6.
6. **Install the cable guide on the secondary shoe web with the flanged holes fitted into the hole in the secondary shoe web. Thread the cable around the cable guide groove (Fig. 7).**

It is imperative that the cable be positioned in this groove and not between the guide and the shoe web.

7. Install the secondary shoe to anchor (long) spring (Fig. 6).

Be certain that the cable end is not cocked or binding on the anchor pin when installed. All parts should be flat on the anchor pin. Remove the brake cylinder clamp.

8. Apply high-temperature grease (C1AZ-19590-B) to the threads and the socket end of the adjusting screw. Turn the adjusting screw into the adjusting pivot nut to the limit of the threads and then back off 1/2 turn.

Interchanging the brake shoe adjusting screw assemblies from one side of the truck to the other would cause the brake shoes to retract rather than expand each time the automatic adjusting mechanism operated. To prevent installation on the wrong side of the vehicle, the socket end of the adjusting screw is stamped with an **R** or **L** (Fig. 8). The adjusting pivot nuts can be distinguished by the number of lines machined around the body of the nut. Two lines indicate right hand nut; one line indicates a left hand nut.

9. Place the adjusting socket on the screw and install this assembly between the shoe ends with the adjusting screw nearest the secondary shoe.
10. Hook the cable hook into the hole in the adjusting lever from the backing plate side. The adjusting levers are stamped with an **R** or **L** to indicate their installation on the right or left hand brake assembly (Fig. 8).
11. Position the hooked end of the adjuster spring in the large hole in the primary shoe web, and connect the loop end of the spring to the adjuster lever hole.
12. Pull the adjuster lever, cable and

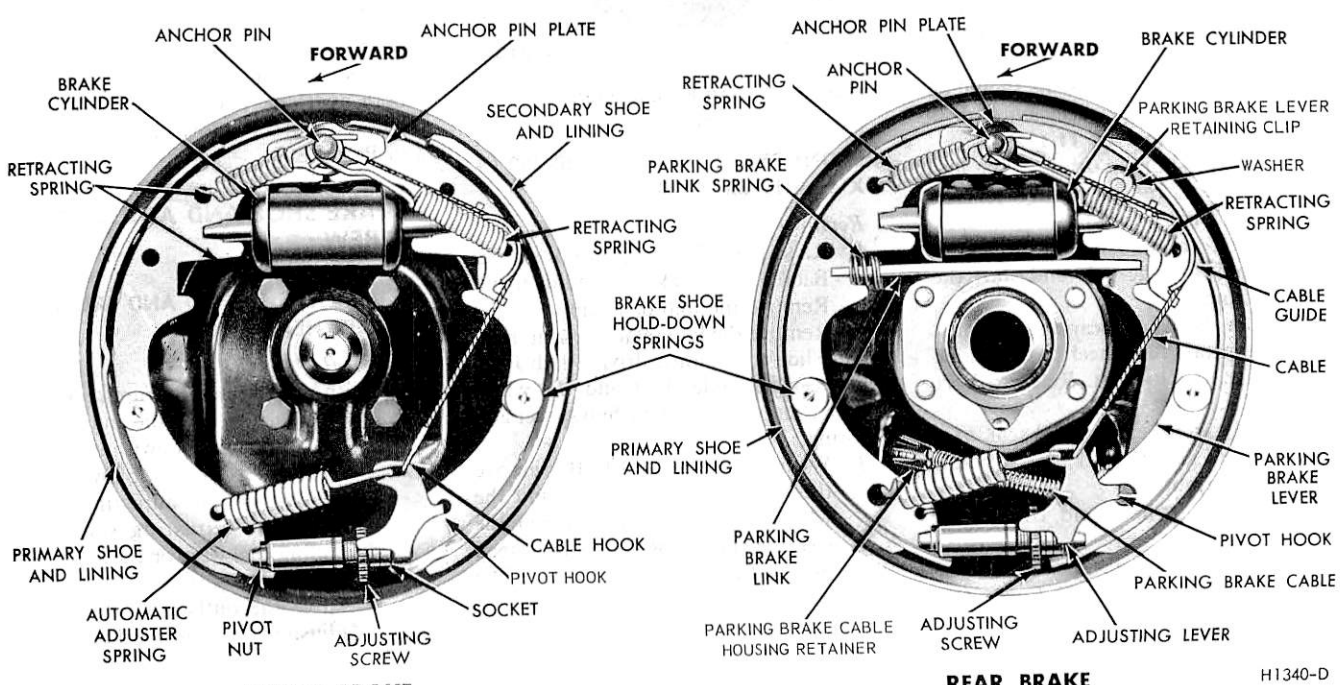

FIG. 7 Self Adjusting Brake Assemblies—F-100-250 4 x 4, E-100-200, and Bronco

automatic adjuster spring down toward the rear to engage the pivot hook in the large hole in the secondary shoe web (Fig. 7).

13. After installation, check the action of the adjuster by pulling the section of the cable between the cable guide and the adjusting lever toward the secondary shoe web far enough to lift the lever past a tooth on the adjusting screw wheel. The lever should snap into position behind the next tooth, and release of the cable should cause the adjuster spring to return the lever to its original position. This return action of the lever will turn the adjusting screw one tooth.

If pulling the cable does not produce the action described, or if the lever action is sluggish instead of positive and sharp, check the position of the lever on the adjusting screw toothed wheel. With the brake in a vertical position (anchor at the top), the lever should contact the adjusting wheel one tooth above the center line of the adjusting screw. If the contact point is below this center line, the lever will not lock on the teeth in the adjusting screw wheel, and the screw will not be turned as the lever is actuated by the cable.

To determine the cause of this condition:

a. Check the cable end fittings. The cable should completely fill or extend slightly beyond the crimped section of the fittings. If it does not meet this specification, possible damage is indicated and the cable assembly should be replaced.

b. Check the cable guide for damage. The cable groove should be parallel to the shoe web, and the body of the guide should lie flat against the web. Replace the guide if it shows damage.

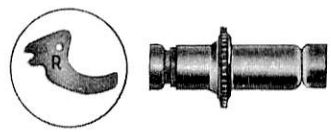
c. Check the pivot hook on the lever. The hook surfaces should be square with the body on the lever for proper pivoting. Repair the hook or replace the lever if the hook shows damage.

d. See that the adjusting screw socket is properly seated in the notch in the shoe web.

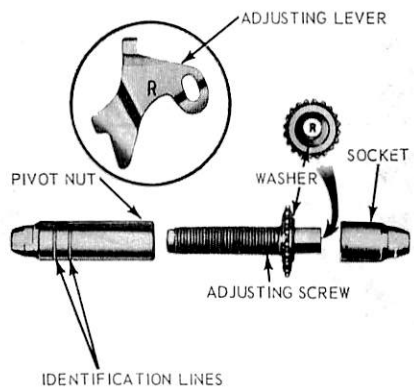
F-250 (HEAVY DUTY) AND F-350 (REAR) E-300, P-350-400 SERIES—WEB LEDGE

Removal

1. Remove the wheel and drum. If the drum does not clear the brake shoes, retract the brake shoes as shown in Fig. 4



F-250 (H.D.)-F-350, E-300, P-350-P-400



F-100-F-250, E-100, E-200 AND BRONCO
H1621-C

FIG. 8 Adjusting Screw and Lever Identification—F-100-250 (rear), E-100-200 and Bronco

2. On a front wheel, remove the spring-clip retainer fastening the adjusting cable anchor fitting to the brake anchor pin (Fig. 9).

On a rear wheel, remove the parking brake lever assembly retaining nut from behind the backing plate and remove the parking brake lever assembly (Fig. 10).

From this point on the disassembly of the front and rear brake assemblies are the same.

3. Remove the adjusting cable assembly from the anchor pin, cable guide and adjusting lever.
4. Remove the brake shoe retracting springs.
5. Remove the brake shoe hold-down spring from each shoe.
6. Remove the brake shoes and adjusting screw assembly.
7. Disassemble the adjusting screw assembly.

Installation

1. Clean and ledge pads (6) on the carrier plate. Sand lightly to bare metal.
2. **Apply a light coat of (C1AZ-19590-B) high temperature grease on the ledge pads of the backing plate. Also apply C1AZ-19590-B high temperature grease to the retracting and hold-down spring contacts on the brake shoes and carrier plate.**
3. Apply C1AZ-19590-B high temperature grease on the threads and socket end of the adjusting screw.
4. Install the upper retracting spring on the primary and secondary shoes as shown in Fig. 9 and position the shoe assembly on the backing plate with the wheel cylinder push rods positioned in the shoe slots.
5. Install the brake shoe hold-down springs (Fig. 10).
6. Install the brake shoe adjustment screw assembly (the slot in the head of the adjusting screw toward the primary shoe), lower retracting spring, adjusting lever spring, adjusting lever assembly and connect the adjusting cable to the adjusting lever. Position the cable in the cable guide and install the cable anchor fitting on the anchor pin.

Interchanging the brake shoe adjusting screw assemblies from one side of the truck to the other would cause the brake shoes to retract rather than expand each time the automatic adjusting mechanism operated. To prevent installation on the wrong side of the vehicle, the socket end of the adjusing screw is stamped with an **R** or **L** (Fig. 8). The adjusting pivot nuts can be distinguished by the number of lines machined around the body of the nut. Two lines indicate right hand nut; one line indicates a left hand nut.

7. On a rear wheel, install the parking brake assembly in the anchor pin and secure with the retaining nut behind the carrier plate.
8. Adjust the brakes before installing the drums, using Rotunda Tool HRE-8650, as outlined in this Part.

BRAKE WHEEL CYLINDER

Removal

1. Remove the wheel, drum, and brake shoes. Remove the cylinder-to-shoe connecting links.
2. Disconnect the brake line from the brake cylinder.
3. Remove the brake cylinder retaining bolts and lockwashers, and then remove the cylinder from the backing plate.

Installation

1. Position the brake cylinder on the backing plate and install the retaining bolts and lockwashers.
2. Install a new gasket on the brake line fitting and connect the line to the brake cylinder.
3. Install the brake shoes and the connecting links between the shoes and cylinder. Install the drum and the wheel.
4. Adjust the brakes and bleed the

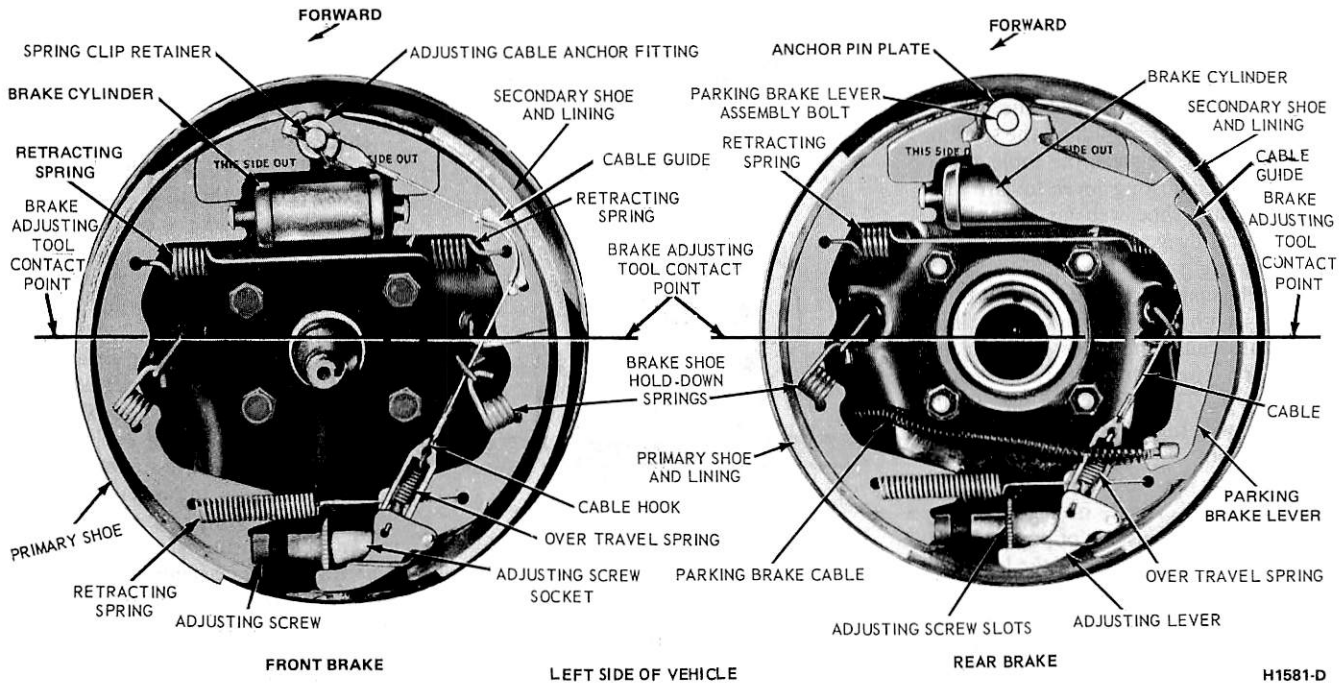


FIG. 9 Self Adjusting Brake Assemblies—F-250 (Heavy Duty)—and F-350 (rear) E-300 and P-350-400 (Front and Rear)

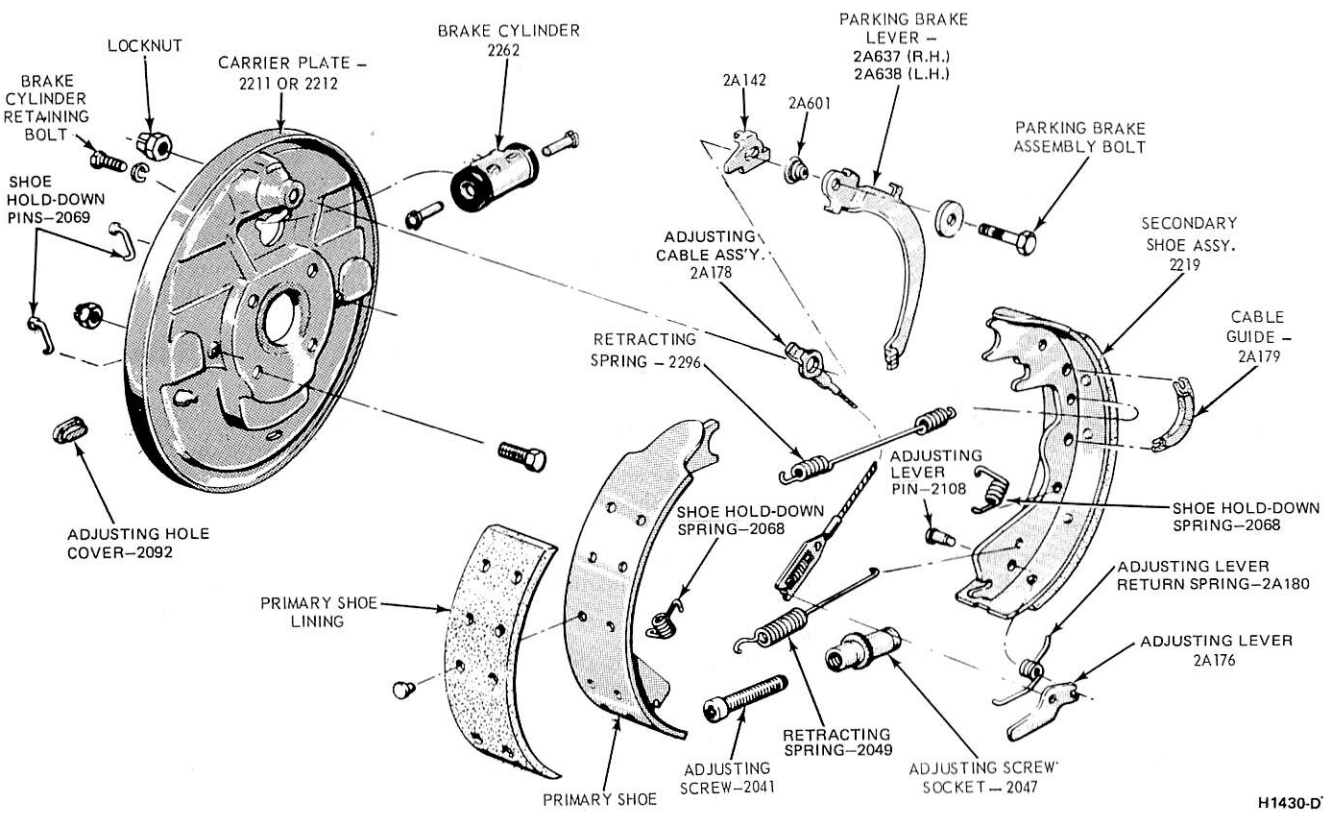

FIG. 10 Rear Web Ledge Single Anchor Brake—Disassembled

system. Check the pedal operation before moving the vehicle.

BRAKE CARRIER PLATE

F-100-250, E-100-200 AND BRONCO (EXCEPT 4 X 4 FRONT)

Removal

1. Remove the wheel and brake drum. Disconnect the brake line from the brake cylinder and submerge the end of the brake line in a can containing a small amount of brake fluid. This will minimize hydraulic line bleeding. Remove the brake shoes and the brake cylinder. On the rear wheels, disconnect the parking brake lever from the cable.
2. **If the rear backing plate is being removed, rotate the axle shaft so that the hole in the axle shaft flange aligns with the backing plate retaining nuts, then remove the nuts. Pull the axle shaft assembly out of the housing with Tool 4235-C, and a slide hammer Tool T50T-100-C, (Fig. 11). Lift off the carrier plate.**

If the front carrier plate is being replaced, remove the bolts and nuts that secure the plate to the front wheel spindle and lift off the plate.

Installation

1. Position the rear carrier plate on the retaining bolts in the axle housing flange. Insert the axle shaft assembly into the housing so that the splines engage the differential side gear, with the bearing retainer sliding onto the retaining bolts and against the carrier plate. Install the retaining nuts through the access hole in the axle shaft flange.

Position the front carrier plate on the wheel spindle and install the retaining bolts and nuts.

2. Install the brake cylinder and brake shoes. On a rear brake, connect the parking brake cable to the lever.
3. Connect the brake line to the brake cylinder, then install the wheel and brake drum. Adjust the brake shoes and bleed the hydraulic system.

F-100 4 X 2 SERIES WITH SPICER 60—3 AXLE—REAR

Brake carrier plate Removal and Installation procedure is similar to that used on the F-100 Ford axle. However, certain precautions are necessary if a new carrier plate is installed, since the side-to-side end play of the rear axle shafts can be affected. When replacing a brake carrier plate with a new or different plate, refer to Group 15—Rear Axle, for assembly procedure including end-play adjustments, etc.

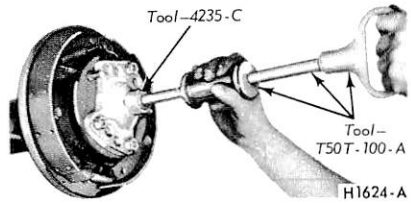

FIG. 11 Axle Shaft Removal

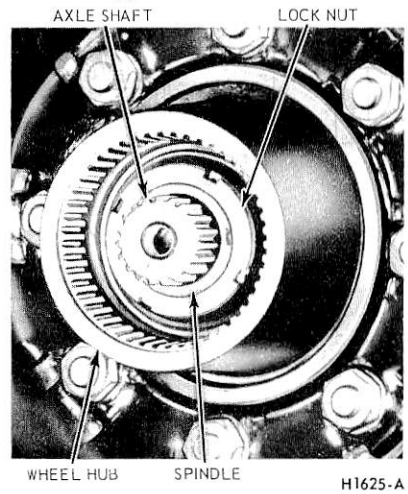

FIG. 12 Front Wheel Hub—Four-Wheel Drive

F-100-250 4 X 4 AND BRONCO SERIES—FRONT

Removal

1. Raise the vehicle on a hoist.
2. Remove the hub grease cap. Remove the hub retaining snap ring, and slide the splined driving hub from between the axle shaft and the wheel hub. Remove the driving hub spacer.

If the vehicle is equipped with a locking type hub, refer to Part 11-12.

3. Remove the lock nut, washer, and wheel bearing adjusting nut from the steering spindle. Remove the wheel, hub and drum as an assembly (Fig. 12). The wheel outer bearing will be forced off the spindle at the same time. Remove the wheel inner bearing cone.
4. Remove the cap screws which retain the brake backing plate and spindle to the spindle arm. Remove the brake backing plate and spindle.

Installation

1. Position the spindle and the brake carrier plate on the steering arm, and then install the retaining cap screws.
2. Install the wheel inner bearing cone on the spindle. Install the wheel hub and drum. Install the driving hub spacer and then the wheel outer bearing cone and adjusting nut.
3. Follow the Procedure under Front Wheel Bearing Adjustment in Part 11-12.
4. Install the driving hub and snap ring. Install the grease cap.

300 THROUGH 900 SERIES

Removal

1. From front wheel spindles, remove the hub and drum attaching parts (axles under 9,000 lbs capacity grease cap and gasket if so equipped, cotter pin, bearing adjusting nut and flat washer). (Axles 9,000 lbs capacity or over-grease cap and gasket, lock nut, dimpled washer, locking ring, and bearing adjusting nut and pin assembly). Then, remove the outer wheel bearing and the hub and drum assembly from the spindle.
2. On rear wheels, remove the rear axle shaft flange retaining nuts and axle shaft. Remove the rear wheel bearing lock nut, lock washer, and adjusting nut, then remove the hub and drum assembly from the axle housing. Discard the grease seal.
3. Remove the brake shoes and adjusting screw from the carrier plate as outlined in this Section. Disconnect the brake line from the brake cylinder and submerge the end of the brake line in a can containing a smal amount of clean brake fluid, This will minimize hydraulic line bleeding.
4. Remove the carrier plate retaining bolts and nuts, then remove the carrier plate from the front wheel spindle or rear axle housing.
5. Remove the attaching bolts and lock washers, and the brake cylinder from the carrier plate.

Installation

1. Assemble the brake cylinder to the backing plate with the attaching bolts and lock washers.
2. Mount the carrier plate to the front wheel spindle or to the rear axle housing flange, and secure with the attaching bolts and nuts.
3. Install the brake shoes and adjusting screw to the carrier plate as outlined in this section. Connect the brake line to the brake cylinder.
4. Install a front wheel hub and drum assembly and the outer wheel bearing to the spindle. Install the hub and drum attaching parts (axle under 9,000 lbs capacity-flat washer, bearing adjusting nut, cotter pin, grease cap, and gasket if so equipped, axles 9,000 lbs capacity or outer bearing adjusting nut and pin assembly, locking ring, dimpled washer, lock nut, and grease cap and gasket). Adjust the front wheel

bearings as outlined in Group 11.

Install a rear wheel hub and drum assembly on the rear axle housing. **The rear hub oil seal must be replaced whenever a hub is removed or installed.** Install the outer bearing and the adjusting nut, then adjust the wheel bearings as outlined in Group 11. Install the lock washer and lock nut, then torque to specifications. Install the rear axle shaft, gasket and attaching nuts, then torque to specifications.

5. Install the wheel and tire.
6. Bleed the hydraulic system and adjust the brake shoes.

BRAKE MASTER CYLINDER

F-100-600, P-350-400 AND L-500-600 SERIES— POWER BRAKE—DASH MOUNTED BOOSTER

Removal

1. With the engine stopped, depress the brake pedal to expell vacuum from the brake booster system.
2. Disconnect the hydraulic lines from the brake master cylinder.
3. Remove the brake booster to master cylinder retaining nuts and lockwashers. Remove the master cylinder from the brake booster.

Installation

1. Before installing the master cylinder, check the distance from the outer end of the booster assembly push rod to front face of the brake booster assemby. Turn the push rod adjusting screw in or out as required to obtain the specified length (Fig. 13).
2. Position the master cylinder assembly over the booster push rod and onto the two studs on the booster assembly. Install the attaching nuts and lockwashers and torque them to specifications.
3. Connect the hydraulic brake system lines loosely to the master cylinder.
4. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this Section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with the specified C6AZ-19542-A brake fluid. Install the gasket (diaphragm) and reservoir cover.

F-100-350 AND P-350-400 SERIES—NON-POWER BRAKE

Removal

Refer to Figure 14.

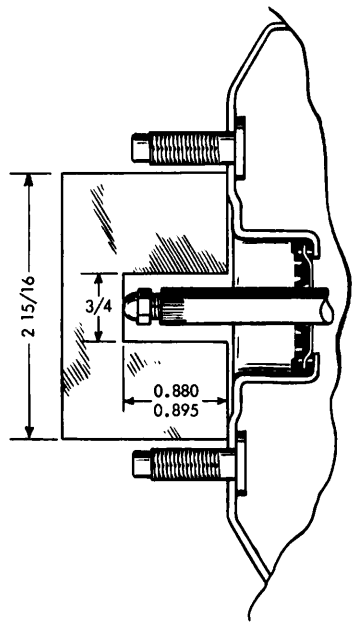

FIG. 13 Bendix Booster Push Rod Gauge Dimensions and Adjustment

1. Working from inside the vehicle below the instrument panel, disconnect the wires from the stop light switch.
2. Disconnect the dust boot from the rear of the master cylinder at the dash panel.
3. Remove the retaining nut, shoulder bolt, spacers and bushing securing the master cylinder push rod and the stop light switch to the brake pedal assembly. Remove the switch.
4. Remove the boot from the master cylinder push rod.
5. Disconnect the brake hydraulic system lines from the master cylinder.
6. Remove the master cylinder to dash panel retaining screws, and remove the master cylinder.

Installation

1. Position the master cylinder assembly on the dash panel within the engine compartment and install the retaining screws and washers. Tighten the screws to specification.
2. Connect the hydraulic brake system lines loosely to the master cylinder.
3. Working from inside the vehicle

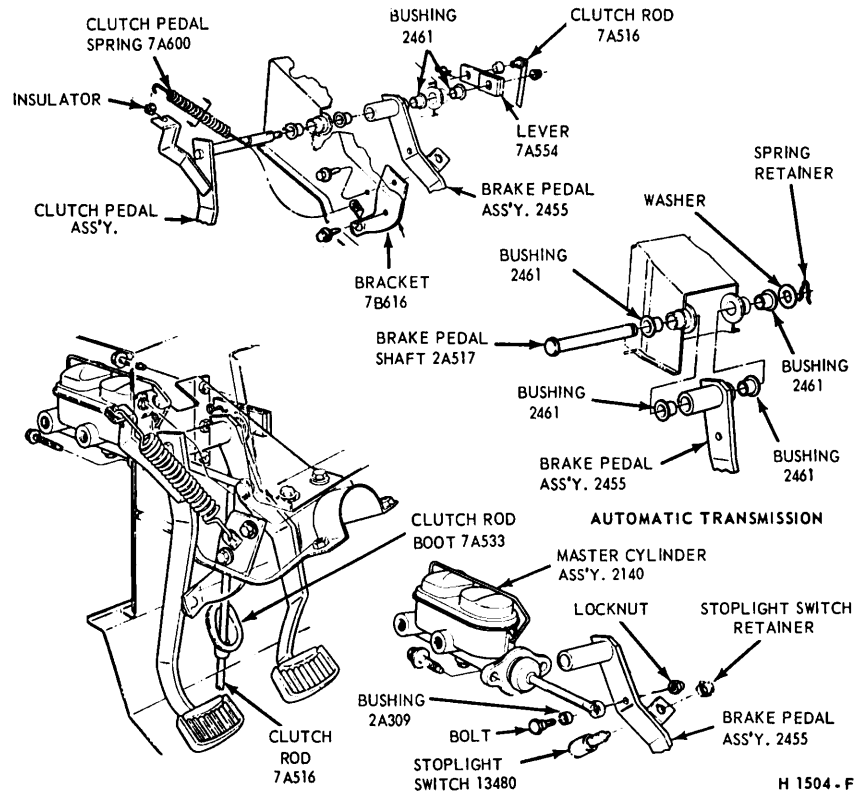

FIG. 14 Dual Master Cylinder and Brake Pedal Installation—Non-Power Brakes—F-100-350

below the instrument panel, position the boot over the push rod and secure the boot to the master cylinder.

4. Lubricate the push rod bushing with lubricant (Lubriplate). Position the bushing in the push rod.
5. Position the stop light switch on the push rod. Install the shoulder bolt and spacers. **Make sure the bushings and spacers are installed properly. Secure the push rod and stop light switch to the brake pedal assembly with the self-locking nut.**
6. Connect the wires to the stop light switch.
7. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this Section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with the specified brake fluid. Install the gasket (diaphragm) and reservoir cover.

ECONOLINE AND BRONCO

Removal

1. Disconnect the wires from the stoplight switch (Fig. 15 and 16).
2. Disconnect the brake hydraulic system lines at the master cylinder.
3. On Bronco models, remove the hair pin retainer and slide the stoplight switch off the brake pedal pin just far enough for the switch outer hole to clear the pin. Remove the stop light switch from the pin.

Econoline models, remove the shoulder bolt and nut retaining the push rod to the brake pedal. Remove the push rod bushing.

4. Slide the master cylinder push rod off the brake pedal pin. Remove the bushings and washers.
5. Remove the master cylinder retaining bolts and remove the master cylinder.

Installation

1. Position the master cylinder assembly on the dash panel and install the retaining bolts. Torque the bolts to specification.
2. Connect the hydraulic brake system lines to the master cylinder.
3. On Bronco models, lubricate the push rod bushing with lubricant (SAE 10W-20W-30). Insert the bushing in the push rod. Coat the washers with the lubricant, and position the push rod and bushing, washers and stop light switch on the brake pedal pin. Install the hair pin type retainer.
4. On Econoline models, lubricate the push rod bushing. Insert the bushing in the push rod and install the shoulder bolt securing the push rod to the brake pedal.
5. Connect the stop light switch wires to the switch.
6. Bleed the hydraulic brake system.

F-500-900, L-500-750 AND LT-800-850 SERIES— SINGLE BRAKE SYSTEM

Removal

If the vehicle is equipped with a vacuum booster, the engine must be stopped and all vacuum must be expelled from the booster system before the hydraulic lines are disconnected.

1. Disconnect the brake line from the brake fitting.
2. Force as much brake fluid as possible from the master cylinder into a suitable container by pushing down the brake pedal all the way several times.
3. On a vehicle with conventional brakes, disconnect the rubber boot from the rear end of the master cylinder in the cab. Remove the bolts that hold the master cylinder against the dash panel, and lift the cylinder away from the push rod and out of the engine compartment.

On vehicles equipped with a dash mounted booster, remove the nuts and washers that secure the master cylinder to the power booster unit, and remove the master cylinder.

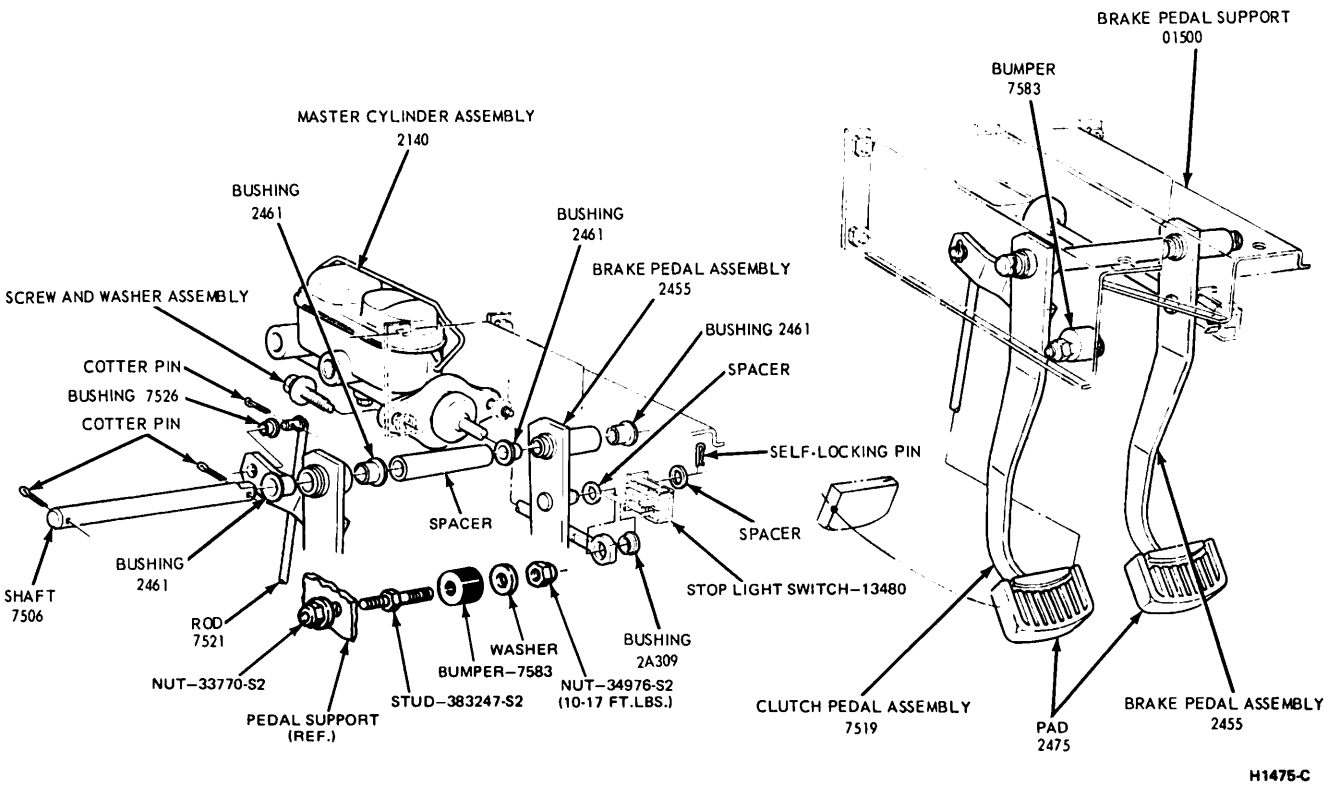

FIG. 15 Brake Master Cylinder and Brake Pedal Installation—Bronco

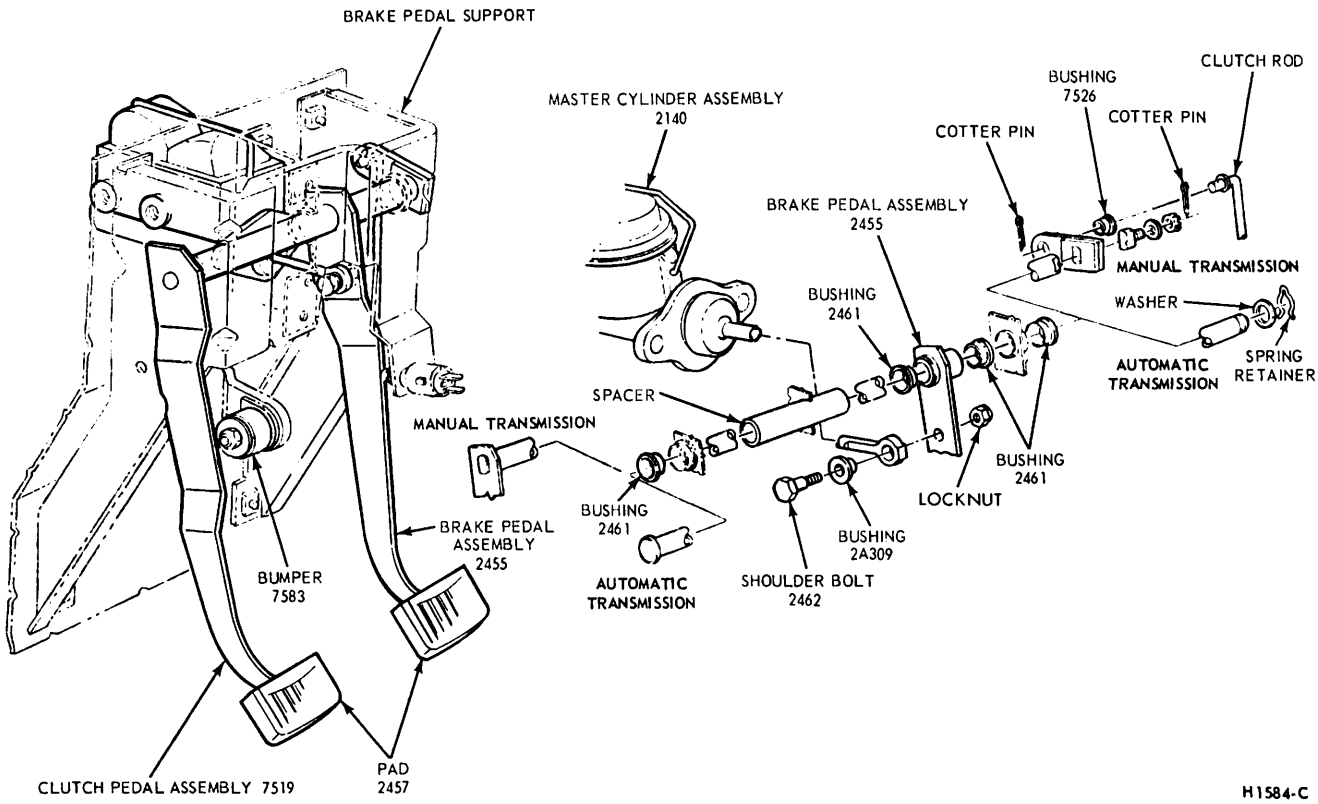

FIG. 16 Brake Master Cylinder and Brake Pedal Installation—Econoline

Installation

1. On a vehicle with conventional brakes, position the rubber boot on the piston push rod, guide the master cylinder over the end of the push rod and position the cylinder against the mounting surface. Install the mounting bolts and torque them to specifications.

On vehicles equipped with a dash-mounted booster, install the master cylinder over the push rod onto the two studs in the power booster body. Install the lock washers and retaining nuts. Torque the nuts to specifications.

2. Connect the brake line to the master cylinder fitting, but leave the brake line fitting loose.
3. Fill the master cylinder reservoir with C6AZ-19542-A extra heavy duty brake fluid to within 1/4 inch of the top of the filler neck.
4. Push the brake pedal down slowly by hand several times to let air escape at the brake line fitting. Hold the pedal down and tighten the brake line fitting. Release the brake pedal. **Do not release the brake pedal until the fitting is tightened as additional air will be introduced into the master cylinder.**

On vehicles equipped with dash-mounted booster, the cylinder can be bled at the bleed screw on the cylinder.

On a vehicle with a frame-mounted brake booster assembly, the master cylinder can be bled at the booster screw(s).

5. After seeing that the master cylinder reservoir is filled with the specified fluid to within 1/4 inch to the top of the filler neck, install the filler cap. Wipe off any fluid from the outside of the cylinder and brake line.
6. Connect the rubber boot to the end of the cylinder.
7. Check and, if necessary, adjust the brake pedal free-travel.

L-, LN-, AND B-SERIES SPLIT BRAKE SYSTEM AND FRAME MOUNTED BOOSTER

Removal

Refer to Figures 17 and 20.

1. Working from inside the vehicle below the instrument panel, disconnect the wires from the stop light switch.
2. On L-and LN-Series, remove the retaining nut, shoulder bolt, spacers and bushing securing the master cylinder push rod and the stop light switch to the brake pedal assembly. Remove the switch.

On B-Series, remove the hair pin clip from the brake pedal pin. Remove the push rod, spacers, stop light switch, and bushing from the brake pedal pin.

3. Remove the boot from the master cylinder push rod.
4. Disconnect the brake hydraulic system lines from the master cylinder.
5. Remove the master cylinder to dash panel retaining screws and remove the master cylinder.

Installation

1. Position the master cylinder assembly on the dash panel within the engine compartment and install the retaining screws and washers. Tighten the screws to specification.
2. Connect the hydraulic brake system lines loosely to the master cylinder.
3. Lubricate the push rod bushing with lubricant (Lubriplate). Position the bushing in the push rod.
4. On L-and LN-Series, position the stop light switch on the push rod, install the shoulder bolt and spacers. **Make sure the bushings and spacers are installed properly. Secure the push rod and stop light switch to the brake pedal assembly with the self-locking nut.**

On B-Series, install the spacers, push rod, bushing and stop light switch on the brake pedal pin. Install the hair pin retainer.

5. Connect the wires to the stop light switch.
6. Bleed the hydraulic brake system as

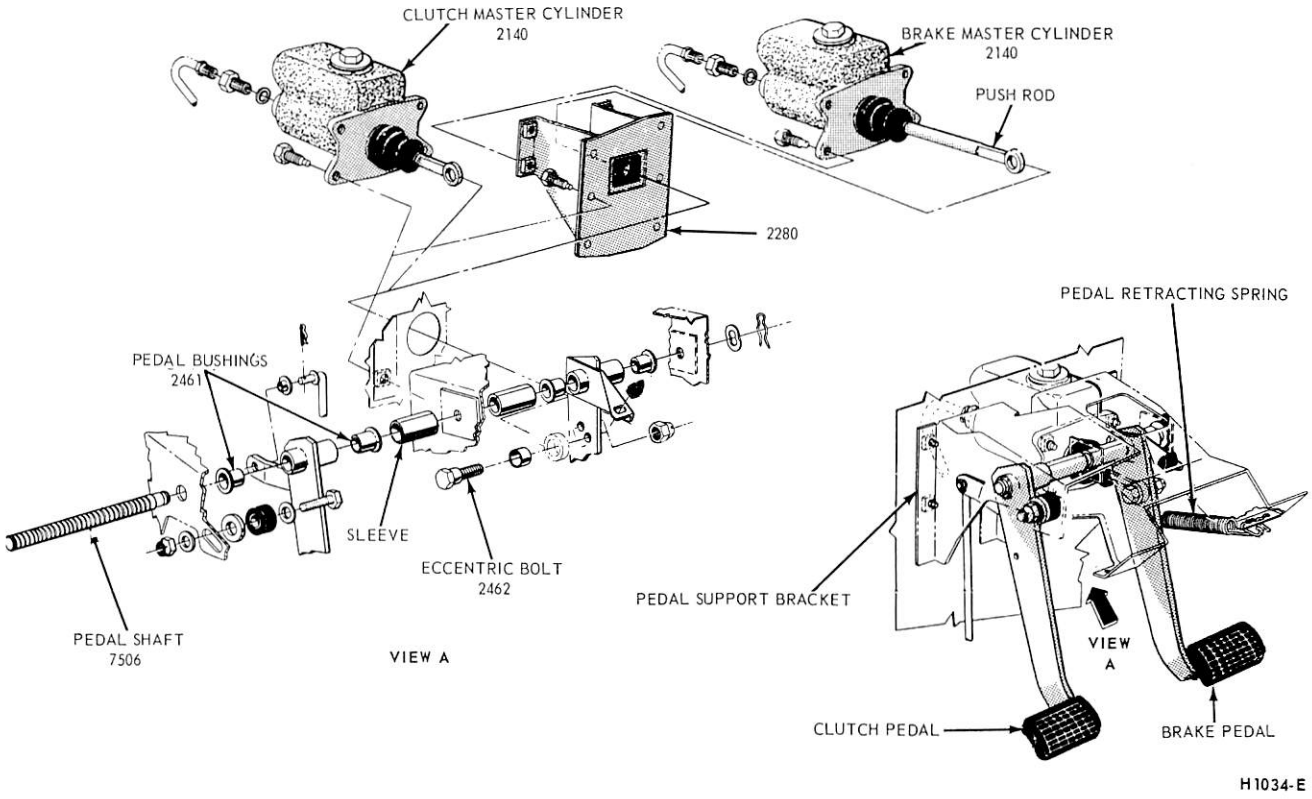

FIG. 17 L-, LN-, or LT-Series Brake Pedal and Related Parts

outlined in this section of the manual. Centralize the differential valve as outlined in this section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with C6AZ-19542-A extra heavy duty brake fluid. Install the gasket (diaphragm) and filler cap.

C-SERIES SINGLE BRAKE SYSTEM

Removal

If the vehicle is equipped with a vacuum or air booster, the engine must be stopped and all vacuum or air pressure must be expelled from the booster system before the hydraulic lines are disconnected.

1. Roll back the floor mat, remove the floor plate, and then disconnect the hydraulic line from the master cylinder.
2. Force as much brake fluid as possible from the master cylinder into a suitable container by pushing down the brake pedal all the way several times.
3. Disconnect the rubber boot from the rear end of the master cylinder in the cab.
4. Remove the two mounting bolts and lower the master cylinder away from the push rod and out of the cab.

Installation

1. With the rubber boot on the piston push rod, guide the master cylinder over the end of the push rod, and position the cylinder against the mounting surface. Install the mounting bolts, and torque them to specifications.
2. Connect the brake line to the master cylinder fitting, but leave the brake line fitting loose.
3. Fill the master cylinder reservoir with the specified brake fluid to within 1/4 inch of the top of the filler neck.
4. Push the brake pedal down slowly by hand. Hold the pedal down and tighten the brake line fitting. Release the brake pedal. **Do not release the brake pedal until the fitting is tightened as additional air will be introduced into the master cylinder. Repeat this procedure until air ceases to escape at the fitting and a firm pedal is obtained.**

On a vehicle with a brake booster assembly, the master cylinder can be bled at the booster bleed screw(s).

5. After seeing that the master cylinder reservoir is filled with the specified C6AZ-19542-A extra heavy duty brake fluid to within 1/4 inch of the top of the filler neck, install the filler cap. Wipe off any fluid from the outside of the cylinder and brake line.
6. Connect the rubber boot to the end of the cylinder. Install the floor plate and secure with the seven retaining screws, and place the floor mat in its proper position.
7. Check and, if necessary, adjust the brake pedal free-travel.

C-SERIES—SPLIT BRAKE SYSTEM

Refer to Figure 18.

All vacuum must be relieved from the booster before hydraulic lines are disconnected.

1. Disconnect the hydraulic lines from the master cylinder. Trap the fluid drip with a shop towel or plug the ports.
2. Remove the bolt and nut connecting the push rod to the brake pedal bell crank and remove the stop light switch, bushing and spacers.
3. Remove the master cylinder mounting bolts and remove the master cylinder from the vehicle.

Installation

Refer to Figure 18.

1. If the master cylinder is being replaced, transfer the outlet ports to the new master cylinder.
2. Position the master cylinder to the

dash panel and install the mounting bolts.
3. Assemble the stop light switch, bushing and spacers on the push rod and install the bolt connecting the push rod to the bell crank.
4. Connect the primary and secondary outlet tubes and tighten to specifications.
5. Bleed the brake system.

DUAL BRAKE MASTER CYLINDER PRESSURE DIFFERENTIAL VALVE ASSEMBLY

Removal

1. Raise the vehicle on a hoist. Disconnect the brake warning light wire from the pressure differential valve assembly switch. **To prevent damage to the brake warning switch wire connector, expand the plastic lugs to allow removal of the shell-wire connector from the switch body.**
2. Disconnect the brake hydraulic lines from the differential valve assembly.
3. Remove the screw retaining the pressure differential valve assembly to the frame side rail and remove the valve assembly.
4. **If the differential valve is to be replaced, remove the brake warning lamp switch and install the switch in the new differential valve. The pressure differential valve assembly and the brake warning lamp switch are separate units and each is serviced as a separate assembly only.**

Installation

1. Mount the pressure differential valve assembly on the frame side rail and tighten the attaching screw.
2. Connect the brake hydraulic system lines to the differential valve assembly and tighten the tube nuts securely.
3. Connect the shell-wire connector to the brake warning lamp switch. **Make sure plastic lugs on the connector hold the connector securely to the switch.**
4. Bleed the brakes and centralize the pressure differential valve as outlined in this Section of the manual.

BRAKE PEDAL ASSEMBLY

F-100-350-SERIES

Removal

Refer to Figure 14.

1. Working inside the vehicle, below the instrument panel, disconnect the wires from the stop light switch.

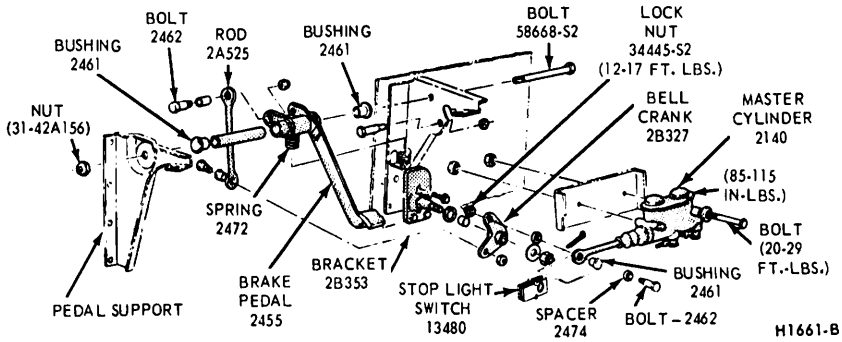

FIG. 18 Dual Master Cylinder and Brake Pedal Installation—C-Series

2. Disconnect the clutch pedal retracting spring and remove the insulators. Remove the retaining nut, shoulder bolt, and bushing securing the push rod to the brake pedal assembly.
3. On an automatic transmission equipped vehicle, remove the retainer, washer, bushings and shaft securing the brake pedal to the support. Remove the brake pedal assembly.
4. On a standard transmission equipped vehicle, remove the cotter pin, nut, washer, bushings and lever securing the brake pedal assembly to the support. Remove the brake pedal assembly.
5. Remove the stop light switch from the bracket on the brake pedal.
6. If required, remove the pedal pad.

Installation

1. If required, install the pedal pad on the brake pedal assembly.
2. Install the stop light switch retainer and the stop light switch in the retainer on the brake pedal.
3. On a standard transmission equipped vehicle, lubricate the bushings with lubricant (Lubriplate).

Insert the bushings in the brake pedal assembly, and install the brake pedal on the shaft. Install the bushings, lever, washer, nut and cotter pin on the shafts.

Install the bushing in the lever. Connect the rod to the lever and install the cotter pin.

4. On an automatic transmission equipped vehicle, lubricate the bushings with lubricant (Lubriplate).

Insert the bushings in the brake pedal assembly. Position the bushing on the shaft. Insert the shaft through the support and the pedal assembly.

Insert the outer bushing on the shaft and install the washer and retainer.

5. Lubricate the push rod bushing with lubricant (Lubriplate). Position the bushing on the push rod.
6. Install the shoulder bolt. Secure the push rod to the brake pedal assembly with the self-locking nut.
7. Connect the wire to the stop light switch.
8. Install the clutch pedal retracting spring insulators and the spring.

BRONCO

Removal

Refer to Figure 15.

1. Disconnect the wires from the stop light switch.
2. Remove the hair pin retainer (Fig. 15) and slide the stop light switch off the brake pedal pin just far enough for the switch outer hole to clear the pin. Remove the stop light switch from the pin.
3. Slide the master cylinder push rod off the brake pedal pin. Remove the bushing and washers.
4. Remove the cotter pin from the right side of the brake and clutch pedal shaft.
5. Slide the shaft toward the left, just enough to allow removal of the brake pedal and two brake pedal bushings.

Installation

1. **Coat the brake pedal bushings and the shaft with lubricant (Oil SEA 10W-20W-30).**
2. Position the bushings, pedal and shaft on the brake pedal support and install the retaining cotter pin (Fig. 15). Spread the cotter pin ends.
3. Lubricate the master cylinder push rod bushing with the lubricant. Insert the bushing in the push rod. Coat the washers with the lubricant, and position the push rod and bushing, washers and stop light switch on the brake pedal pin. Install the hair pin type retainer.
4. Connect the wires to the stop light switch.

ECONOLINE

Removal

Refer to Figure 16.

1. Remove the shoulder bolt and nut

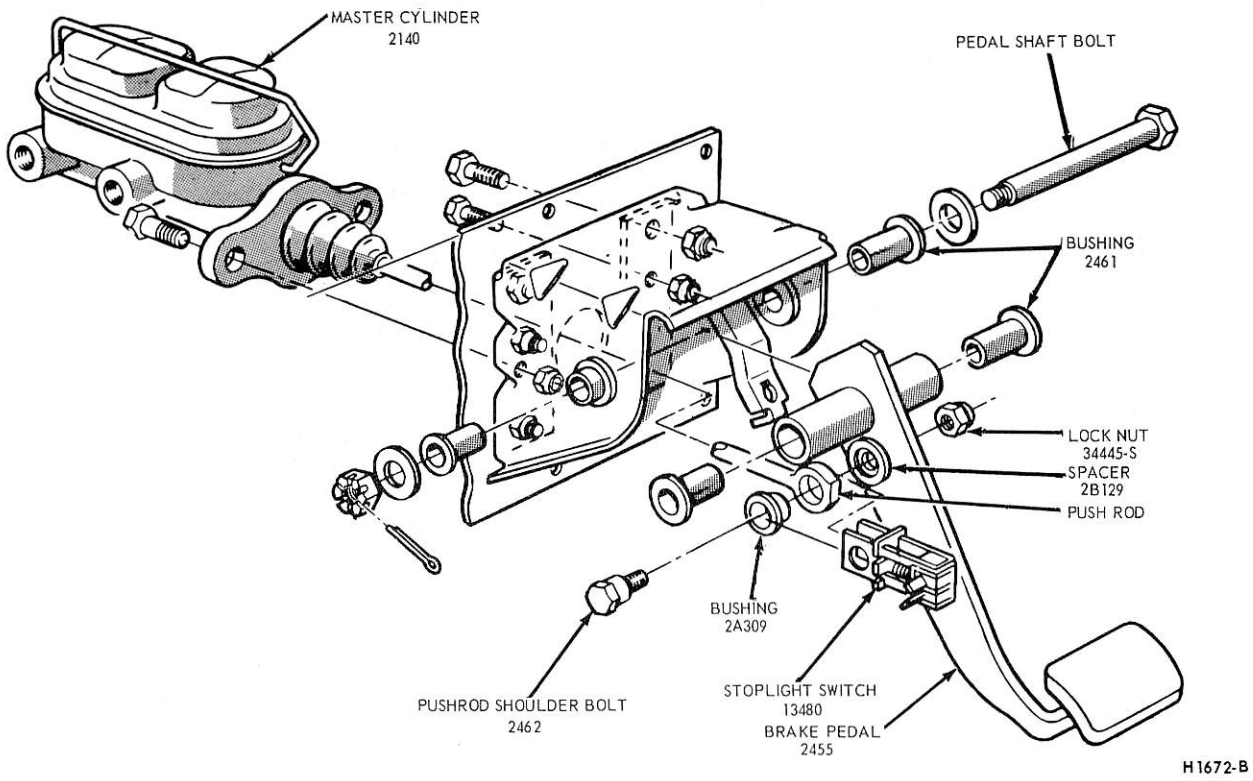

FIG. 19 Brake Pedal and Master Cylinder Installation—P-350-400

retaining the master cylinder push rod to the brake pedal.

2. On models with a manual transmission, remove the clutch lever from the clutch pedal shaft.

On models with an automatic transmission, remove the spring retainer and washer from the right end of the clutch pedal shaft.

3. Slide the shaft toward the left, just enough to allow removal of the brake pedal and two brake pedal bushings.

Installation

1. Coat the brake pedal bushings and the shaft with lubricant (Oil SAE 10W-20W-30).
2. Position the bushings, pedal and shaft on the brake pedal support.

On Models with a manual transmission, install the clutch lever on the clutch pedal shaft.

On Models with an automatic transmission, install the washer and spring retainer on the clutch shaft.

3. Lubricate the master cylinder push rod bushing with the lubricant. Insert the bushing in the push rod. Install the shoulder bolt and nut securing the master cylinder push rod to the brake pedal.

L-500-900, LN-, AND LT-SERIES

Removal

1. Remove the brake pedal retracting spring (Fig. 17).
2. Remove the brake master cylinder push rod eccentric bolt nut, and remove the bolt and two nylon bushings.
3. Remove the nut from the pedal shaft. Then slide the shaft to the left and remove the brake pedal and sleeve.
4. Remove the two bushings from the pedal, and remove the bumper from the pedal extension bracket if so equipped.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Install the bumper on the pedal extension bracket (if so equipped), and position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly and sleeve in the pedal support bracket. Slide the pedal shaft through the sleeve and pedal and secure with the nut. Torque the nut to specifications.
4. Position the nylon bushings in the bore of the push rod. Connect the push rod to the brake pedal with the eccentric bolt and nut. Install the pedal retracting spring.

P-350-400-SERIES

Removal

Refer to Figure 19.

1. **Remove the brake master cylinder push rod shoulder bolt nut, and remove the bolt and nylon bushing.**
2. Remove the cotter pin and nut from the pedal shaft. Then slide the shaft to the right and remove the brake pedal sleeve.
3. Remove the two bushings from the pedal and the two bushings from the pedal support.

Installation

1. Coat all bushings and pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Position the nylon bushings in the brake shaft bore and the support bracket.
3. Position the brake pedal assembly in the pedal support bracket. Slide the pedal shaft through the pedal and secure with the nut. Torque the nut

to specifications. Install the cotter pin.

4. **Position the nylon bushings in the bore of the push rod. Connect the push rod to the brake pedal with the sholder bolt and nut.**

B-SERIES

Removal

1. Remove the brake pedal retracting spring (Fig. 20).
2. Remove the clevis pin retaining clip and remove the pin, spacers, master cylinder push rod bushing and switch assembly.
3. Remove the clip from the pedal shaft. Then slide the shaft to the left and remove the brake pedal.
4. Remove the two bushings from the pedal.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly in the pedal support bracket. Slide the pedal shaft through the pedal and secure with the retaining clip.
4. Position the nylon bushing in the bore of the push rod. Connect the push rod, switch assembly and spacers to the brake pedal with the clevis pin and secure with the retaining clip.
5. Install the pedal retracting spring.

C-SERIES

Removal

1. Remove the brake pedal retracting spring (Figs. 18 and 21).
2. Remove the brake master cylinder push rod retaining bolt nut, bolt and nylon bushings.
3. Remove the brake pedal bumper-to-bracket retaining nut. Then remove the bolt and bumper.
4. On models with a single hydraulic brake system, remove the master cylinder push rod by pulling up on the tab on the push rod boot, and remove the push rod and boot from the cylinder.
5. Remove the nut from the bolt, slide the bolt to the right and remove the

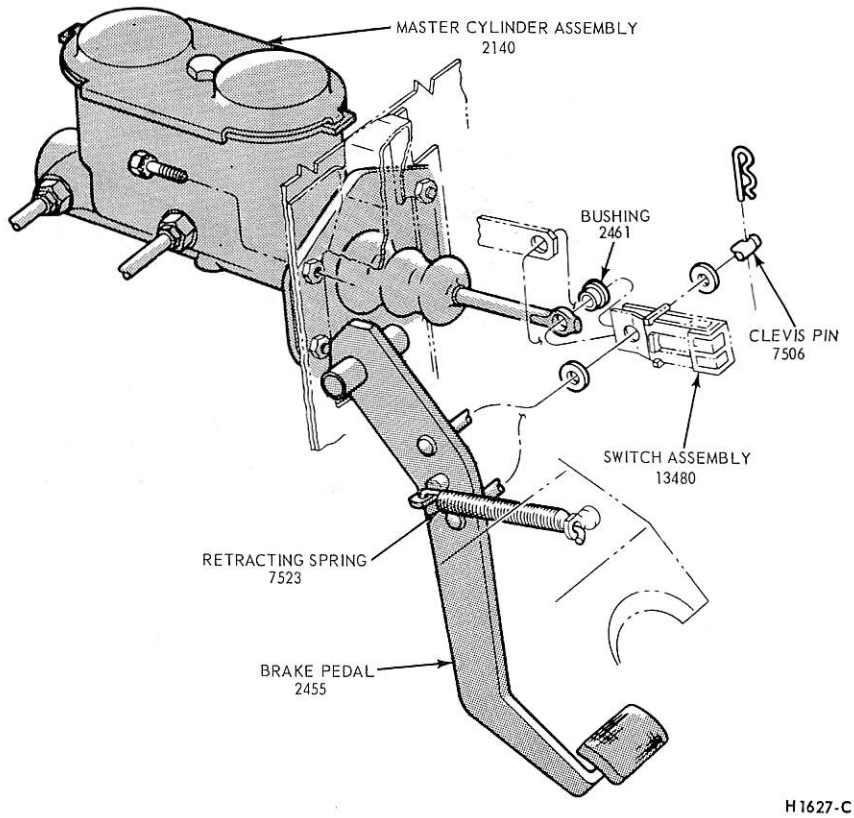

FIG. 20 F-B-Series Brake Pedal and Related Parts

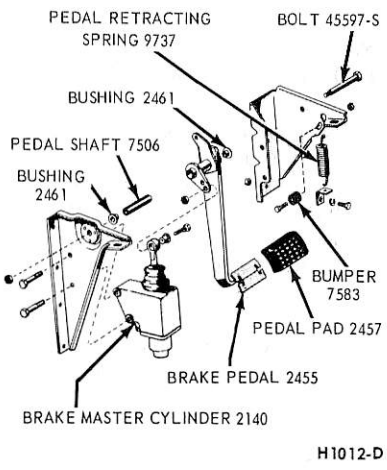

FIG. 21 Single Master Cylinder and Brake Pedal Installation—C-Series

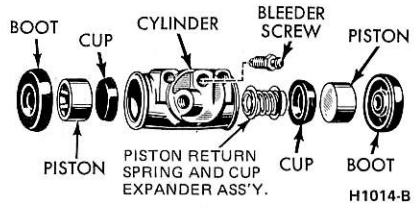

FIG. 22 Double Servo Brake Cylinder

brake pedal assembly, sleeve and bushing.

6. Remove the bushings from the pedal assembly.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant. Position the nylon bushings in the brake pedal shaft bore.
2. Position the brake pedal assembly

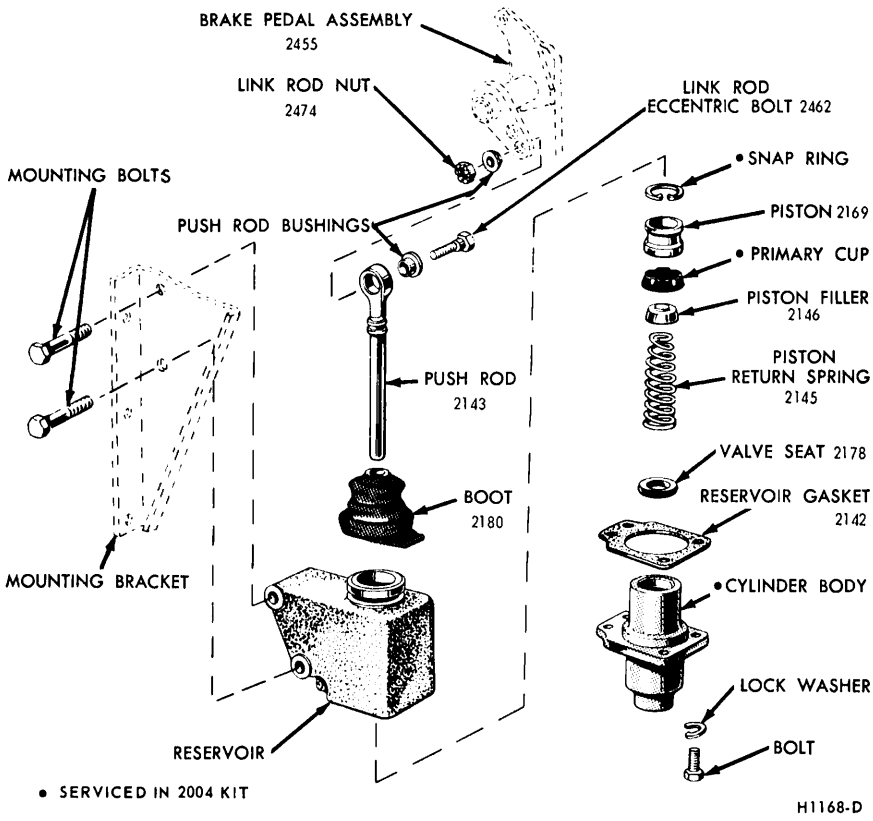

FIG. 23 C-Series Single Brake Master Cylinder

sleeve and bushing in the pedal support bracket, slide the bolt to the left and install the nut. Torque the nut to specifications.
3. On models with a single hydraulic brake system, install the push rod and boot in the master cylinder.
4. On models with a single hydraulic brake system, install the pedal bumper bolt, bumper and nut. Tighten the nut securely.
5. Install the two nylon bushings in the push rod bore, and install the push rod retaining bolt and nut.
6. Install the pedal retracting spring.

OVERHAUL

BRAKE WHEEL CYLINDER

Disassembly

1. With the wheel cylinder removed, remove the rubber boots from the ends of the brake cylinder. Remove the pistons, cups, and piston return spring and piston expander assembly from the cylinder (Fig. 22).
2. Remove the bleeder screw from the cylinder.

Assembly

1. Coat all brake cylinder parts with clean extra heavy duty brake fluid C6AZ-19542-A.
2. Install the bleeder screw (Fig. 22) in the brake cylinder.
3. Place the piston return spring and piston expander assembly, cups, and pistons in the cylinder bore, and install a boot and link over each end of the cylinder, clamp the brake cylinder pistons against the ends of the cylinder. **When a brake cylinder repair kit is used, install all of the parts supplied in the kit.**

MASTER CYLINDER

SINGLE BRAKE SYSTEM

Disassembly

1. With the master cylinder removed, clean the outside of the master cylinder, and remove the filler cap and gasket. Pour out any brake fluid that may remain in the cylinder and reservoir.

On a C-Series truck master cylinder (Fig. 23), remove the 4 bolts that hold the cylinder body on the reservoir, and remove the gasket. Press down on the piston to compress the return spring, and remove the snap ring. Remove the piston, primary cup, piston filler, return spring, check valve, and check valve seat.

On vehicles equipped with a frame mounted vacuum brake booster, the check valve is installed in the booster instead of in the master cylinder.

2. On a L-, LN-, P-, or LT-Series truck master cylinder with a box-shaped reservoir, remove the fitting and gaskets from the forward end of the cylinder. Discard the gaskets. Remove the snap ring from the bore at the rear end of the cylinder, and remove the stop plate, piston cup, spring, check valve, and seat from the cylinder bore. If necessary, blow through the forward bolt hole to remove the parts.

Remove the bolt type fitting from the forward end of the cylinder. Remove the snap ring from the bore at the rear end of the cylinder, and remove the piston, cup, spring, and valve seat. Remove the rubber bumper from the pistons (systems without booster only).

Assembly

1. Dip all parts except the master cylinder body in clean hydraulic brake fluid. **Use only C6AZ-19542-A heavy-duty brake fluid.**
2. On a L-, LN-, P-, LT-Series truck with a box-shaped master cylinder reservoir, install the brake fitting, bolt, and new gaskets on the forward

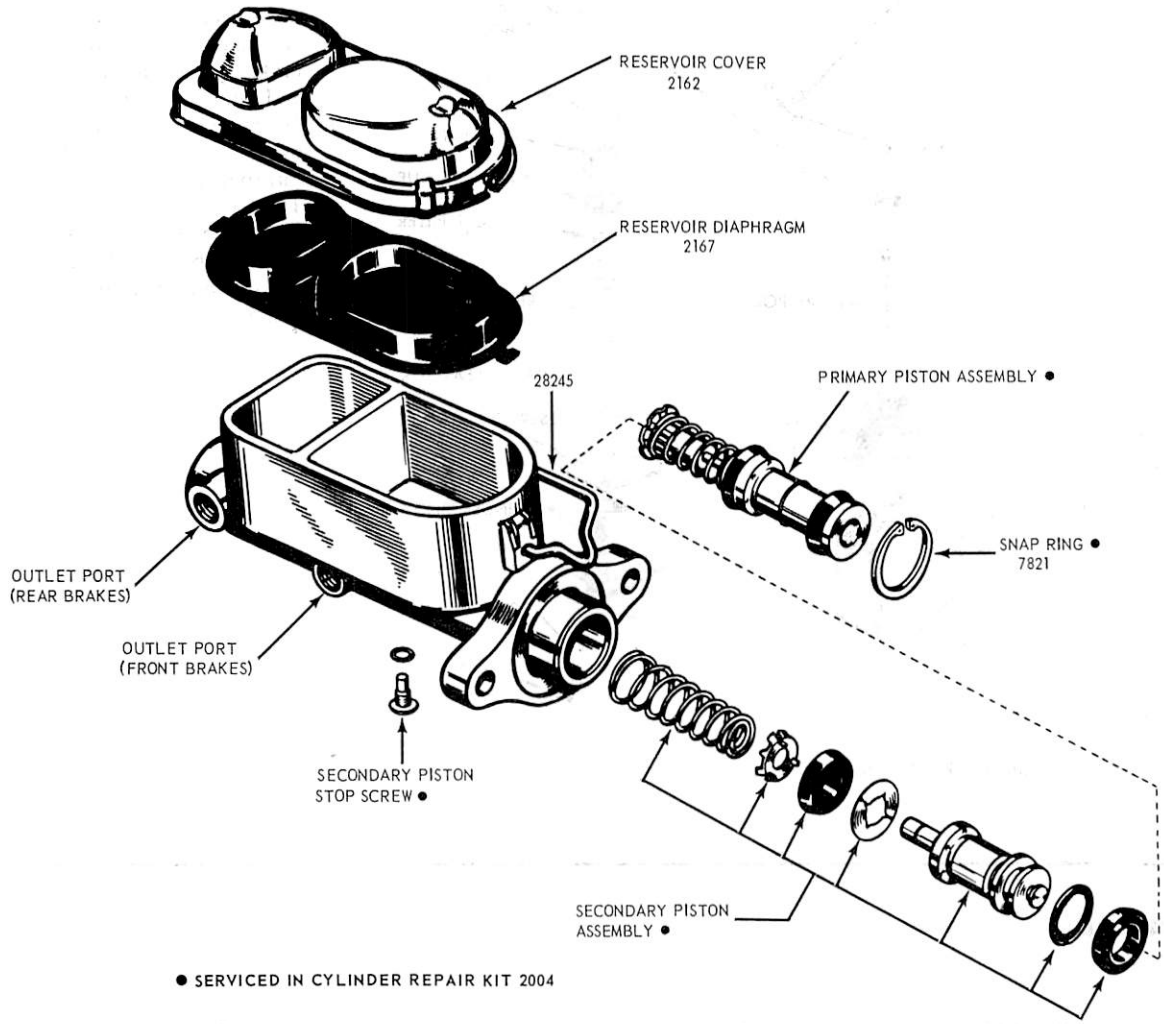

FIG. 24 Dual Master Cylinder Disassembled—F-100-F-350 4 x 2

end of the cylinder. Install the valve seat, valve, spring, cup, piston, and stop plate in the cylinder bore. Install the snap ring in the rear end of the bore.

3. On a C-Series truck master cylinder, install the valve seat, valve, spring, piston filler, cup and piston in the cylinder bore, push down on the piston to compress the spring and install the snap ring in the bore. Position a new gasket over the cylinder body and mount the body to the reservoir. Secure with 4 bolts. Tighten bolts securely.

F-100-350, E-100-300, P-35 AND BRONCO

Refer to Figures 24 and 25.

The master cylinder must be removed from the vehicle to be overhauled.

When a repair is necessary on the master cylinder, it is required practice during the warranty period to replace the cylinder as a unit instead of overhauling the cylinder with a service repair kit.

Disassembly

1. Clean the outside of the master cylinder and remove the filler cap and gasket (diaphragm). Pour out any fluid that remains in the cylinder.
2. Unscrew the piston stop from the bottom of the cylinder body. Remove the O-ring seal from the piston stop. Discard the seal.
3. Remove the push rod boot, if so equipped, from the groove at the rear of the master cylinder and slide the boot away from the rear of the master cylinder.
4. Remove the snap ring (Fig. 26) retaining the primary and secondary piston assemblies within the cylinder body.
5. Remove the push rod (if so equipped) and primary piston assembly from the master cylinder. Discard the piston assembly, including the boot (if so equipped).
6. Apply an air hose to the rear brake outlet port of the cylinder body and carefully blow the secondary piston out of the cylinder body.
7. Remove the return spring, spring retainer, cup protector, and cups from the secondary piston. Discard the cup protector and cups.
8. P-350-400: Place the master cylinder in a vise with the outlet ports up. **Be careful to avoid damage to the master cylinder housing.**
9. P-350-400: Install a spare brake line tube nut in the rear brake outlet port

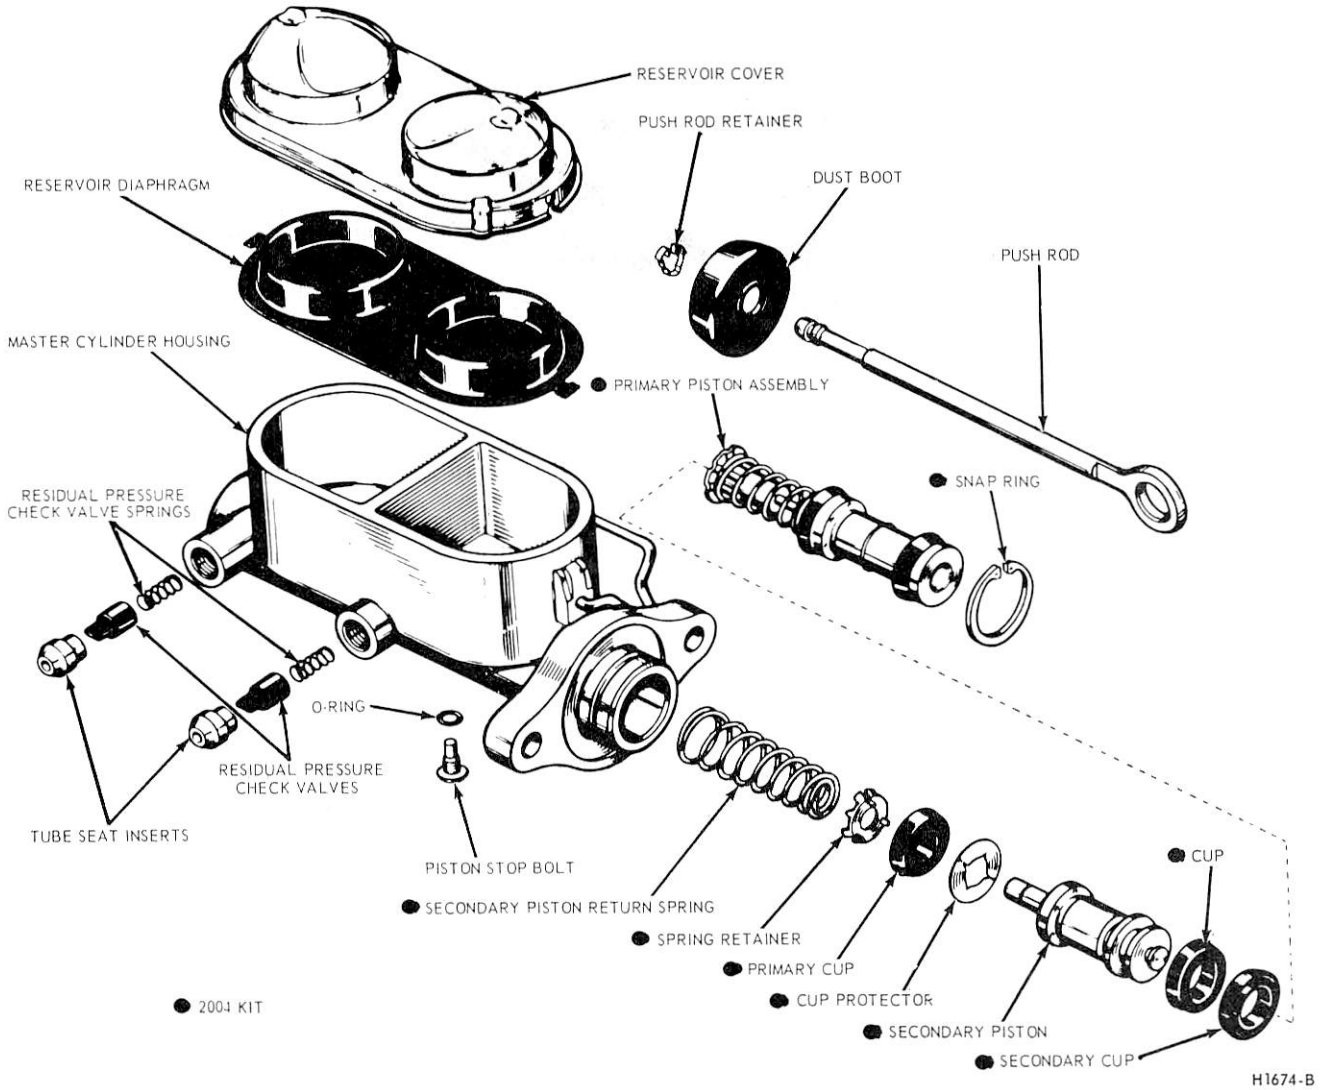

FIG. 25 Dual Master Cylinder Disassembled View—P-350-P-400 Series

(Fig. 27). Place a flat washer on a 1 inch No. 8 x 32 self-tapping screw and thread the screw into the tube seat insert in the port. Hold the screw from turning, and back the tube nut out of the port. This will remove the tube seat insert from the port.

Repeat the same procedure to remove the tube seat insert from the front brake outlet port.

10. P-350-400 ONLY: Remove the master cylinder from the vise, and then remove the residual pressure check valves and check valve springs from the outlet ports (Fig. 25).

Inspection and Repair

1. Clean all parts in clean isopropyl alcohol, and inspect the parts for chipping, excessive wear or damage. Replace them as required. **When**

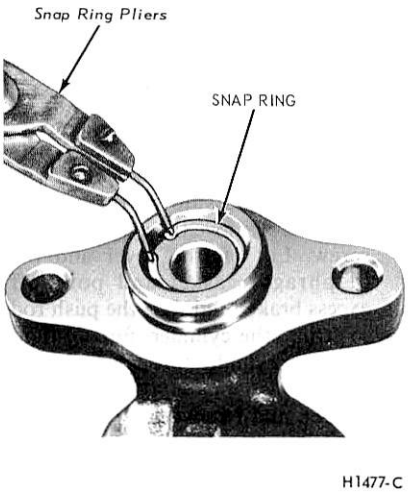

FIG. 26 Removing Snap Ring—Typical

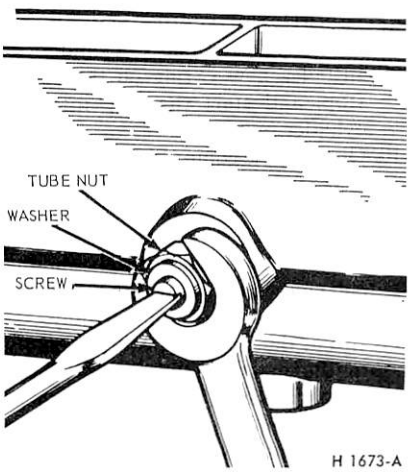

FIG. 27 Removing Residual Check Valve and Tube Seat

using a master cylinder repair kit, install all the parts supplied.

2. Check all recesses, openings and internal passages to be sure they are open and free from foreign matter. Use the air hose to blow out dirt and cleaning solvent. Place all parts on a clean pan or paper.
3. Inspect the hydraulic master cylinder bore for signs of etching, pitting or rust. Replacement of the master cylinder will be required if any of these conditions exist.

Assembly

1. P-350-400: Place the master cylinder in a vise with the outlet ports up. **Be careful to avoid damage to the master cylinder housing.**
2. **P-350-400: Insert a check valve spring in a new residual pressure check valve (P-350-400) and replace the assembly in the rear brake outlet port. Be sure the spring is properly seated in the bottom of the port.**
3. P-350-400: Place a new brass tube seat insert in the port. Be sure the insert is not cocked. Thread a spare brake line tube nut in the port, and turn down the nut until the tube seat insert is bottomed in the port (Fig. 28). Remove the tube nut.
4. Repeat the above procedures at the front brake outlet port.
5. Remove the master cylinder from the vise. Check the outlet ports for brass burrs, and remove the burrs, if present.
6. Dip all the parts except the cylinder body in clean C6AZ-19542-A extra heavy duty brake fluid.
7. Assemble the two secondary cups, back-to-back, in the grooves near the end of the secondary piston. Assemble the cup protector, primary cup, spring retainer and secondary piston return spring on the other end of the secondary piston.
8. Install the secondary piston assembly in the master cylinder.
9. Install a new O-ring on the piston stop, and start the stop into the cylinder body.
10. On a vehicle equipped with standard brakes, position the boot, snap ring and push rod retainer on the push rod. **Make sure the push rod retainer is seated securely on the ball end of the rod.** Seat the push rod in the primary piston assembly.
11. Install the primary piston assembly in the master cylinder. Push the primary piston inward and tighten the secondary piston stop to retain the secondary piston in the bore.
12. On a vehicle equipped with power brakes, position the stop plate and snap ring on the primary piston. Depress the primary piston and install the snap ring in the cylinder body.
13. On a vehicle equipped with standard brakes, press the push rod and pistons inward and install the snap ring in the cylinder body.
14. Bleed the master cylinder.

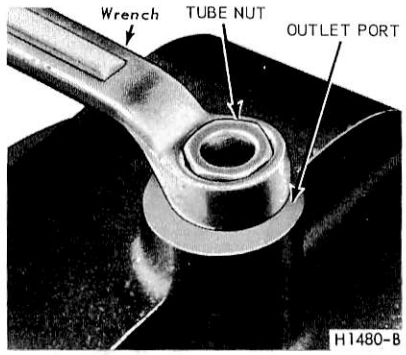

FIG. 28 Installing Residual Check Valve and Tube Seat

Bleeding the Master Cylinder

Before the master cylinder is installed on the vehicle, the unit should be bled.

1. Support the master cylinder body in a vise, and fill both fluid reservoirs with C6AZ-19542-A extra heavy duty brake fluid.
2. Loosely install plugs in the front and rear brake outlet bores. Depress the primary piston several times until air bubbles cease to appear in the brake fluid.
3. Tighten the plugs and attempt to depress the piston. **The piston travel should be restricted after all air is expelled.**
4. Remove the plugs. Install the cover and gasket (diaphragm) assembly, and make sure the cover retainer is tightened securely.

500-950 SERIES—SPLIT HYDRAULIC BRAKES AND FRAME MOUNTED BOOSTER

Disassembly

Refer to Figure 29.

1. Clean the outside of the master cylinder. Remove the cylinder cover screw. Lift off the cover and the diaphragm gasket and pour off excess brake fluid. Use the push rod to stroke the cylinder, forcing fluid from the cylinder through the outlet ports.
2. Loosen and remove the piston stop screw and gasket from the right hand side of the cylinder.
3. Pull back the push rod boot and remove the snap ring from the groove in the end of the cylinder bore as shown in Fig. 26.
4. Remove the push rod and stop plate from the master cylinder.
5. Remove the internal parts from the master cylinder. If the parts will not slide out loosely assemble the cover plate and seal the primary outlet part, then apply air pressure at the secondary outlet port.

Inspection and Repair

1. Clean all parts in isopropyl alcohol. Inspect the parts for chipping, excessive wear or damage. Replace them as required. **When using a master cylinder repair kit, install all the parts supplied.**
2. Check all recesses, openings and internal passages to be sure they are open and free of foreign matter. Passages may be probed with soft copper wire, 0.020 inch OD, or smaller.
3. Minor scratches or blemishes in the cylinder bore can be removed with crocus cloth or a clean up hone. Do not oversize the bore more than 0.007 inch.

Assembly

Refer to Figure 29.

1. Dip all parts except the master cylinder in clean extra heavy duty C6AZ-19542-A hydraulic brake fluid.
2. Install the rear rubber cup on the secondary piston with the cup lip facing the rear. All other cups face the front or closed end of the cylinder.
3. Assemble and install the secondary piston spring, front cup, and the secondary piston.
4. Install the piston stop screw and gasket, making sure the screw enters the cylinder behind the rear of the secondary piston.
5. Assemble and install the primary piston and push rod parts.
6. Locate the stop plate in the seat in the bore and engage the snap ring into the groove at the rear of the cylinder.
7. Install the push rod boot onto the push rod and groove of the cylinder housing.
8. Bleed the master cylinder.

Bleeding the Master Cylinder

Before the master cylinder is installed on the vehicle, the unit should be bled.

1. Support the master cylinder body in a vise, and fill both fluid reservoirs with C6AZ-19542-A extra heavy duty brake fluid.
2. Loosely install plugs in the front and

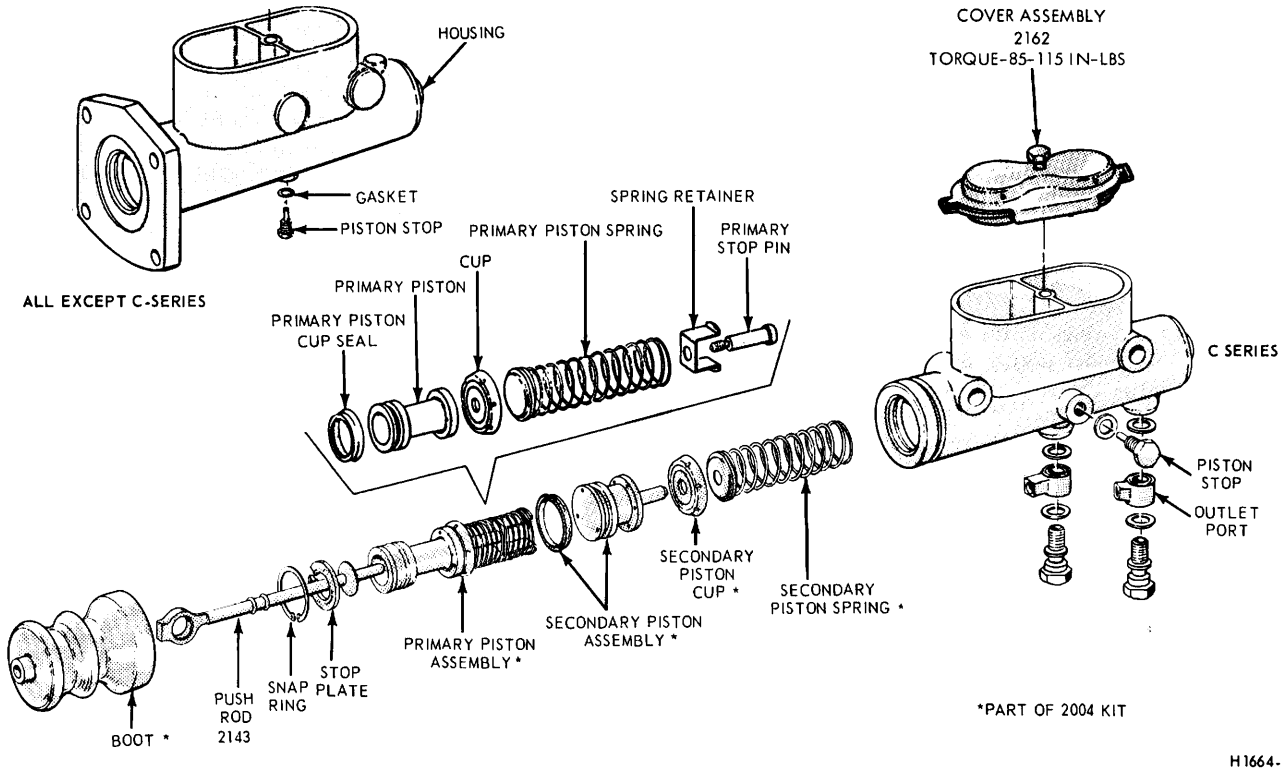

FIG. 29 Dual Master Cylinder—Disassembled View—500-850-Series Truck with Split Hydraulic Brakes and Frame Mounted Booster

rear brake outlet bores. Depress the primary piston several times until air bubbles cease to appear in the brake fluid.

3. Tighten the plugs and attempt to depress the piston. **The piston travel should be restricted after all air is expelled.**
4. Remove the plugs. Install the cover and diaphragm gasket assembly, and make sure the cover screw is tightened securely.

L-AND LN-500-600 SERIES—SPLIT BRAKE SYSTEM AND DASH MOUNTED BOOSTER

Disassembly

Refer to Figure 30.

1. Clean the outside of the cylinder and remove the filler cap and gasket (diaphragm). Pour out any brake fluid that may remain in the reservoir. Stroke the push rod three times to remove fluid from the cylinder bore.
2. Remove the reservoir retainers, washers, and reservoir from the master cylinder body.
3. Remove the two rubber washers from the reservoir and the two O-rings from the reservoir retainers.
4. Remove the snap ring, spring retainer and push rod spring.
5. Unscrew the retainer bushing counterclockwise and remove the push rod, retainer bushing, seal retainer and primary piston from the master cylinder.
6. Remove the primary piston from the push rod and discard it.
7. Remove the seal retainer, and retainer bushing from the push rod. Remove the two lip seals and the two O-rings from the retainer bushing.
8. Unscrew the end cap counterclockwise and remove the end cap and secondary piston assembly from the master cylinder.
9. Remove the snap ring from the secondary piston and remove the piston and return spring from the end cap and stop rod assembly.
10. Remove the two lip seals from the piston.
11. Remove the snap ring from the end cap and remove the secondary piston stop rod, relief port seal spring, the two snap rings and the two split washers from the end cap.
12. Remove the relief port seal from the secondary piston stop rod.
13. Remove the O-rings from the end cap.
14. Remove the primary and secondary port caps and discard.
15. Remove the check valves and springs from the ports.

Assembly

Refer to Figure 30.

1. Wash all metal parts in alcohol before assembly. Dip all parts except the master cylinder body in clean C6AZ-19542-A **extra heavy duty hydraulic brake fluid. When using a master cylinder repair kit, install all of the parts supplied.**
2. Install a new primary piston into the front end of the master cylinder bore. Push the piston through the bore until it is flush with the retainer bushing recess. Use a non-metallic object which will not scratch the bore.
3. Assemble the O-rings and the two lip seals on the retainer bushing. Be sure the lip seals fit into the undercuts in the center of the bushing with their large diameters toward the piston end.
4. Install the retainer bushing onto the closed end of the push rod and push it onto the push rod approximately half way. Be sure the lip seal at the piston end of the retainer bushing remains in the undercut portion of the retainer bushing.
5. Install the seal retainer onto the closed end of the push rod with the

raised lip toward the retainer bushing.
6. Insert the push rod into the master cylinder bore and hook the push rod onto the primary piston.
7. Slide the seal retainer into the recess in the master cylinder bore.
8. Screw the retainer bushing into the master cylinder body and tighten to 15-20 ft-lbs torque.
9. Install the push rod spring with the large end toward the master cylinder and install the spring retainer and snap ring.
10. Install the O-rings on the end cap.
11. Install the relief port seal on the secondary piston stop rod.
12. Place the port seal spring, split washer (largest of two), and snap ring (largest of two) on the piston stop rod.
13. Slide the assembly into the end cap and engage the snap ring into its groove.
14. Install the lip seals on the secondary piston with the large diameters facing outward.
15. Place the secondary piston return spring on the end cap assembly.
16. Compress the spring and place the remaining snap ring and split washer on the piston stop rod.
17. Slide the piston stop rod into the secondary piston and engage the snap ring in its groove.
18. Slide the end cap and piston assembly into the master cylinder bore and screw the end cap into the master cylinder body. Tighten the cap to 15-20 ft-lbs torque.
19. Install washers on the reservoir retainers and place the retainers in the mounting holes of the reservoir.
20. Place the rubber washers and O-rings on the retainers.
21. Place the reservoir and retainer assembly on the master cylinder body and tighten the retainers to 15-20 ft-lbs torque.
22. Replace the springs and check valves in the output ports of the cylinder.
23. Replace the primary and secondary port caps. Tighten to 15-20 ft-lbs torque.
24. Install the mounting seal on the flange of the master cylinder. Install the filler cap and gasket (diaphragm).

Brake Assembly to Rear Axle (500–900 Series)	9/16 x 12, 110–150	1/2 x 13, 75–105	1/2 x 20, 75–105
Brake Drum to Hub Nuts or Bolts (500–900 Series)	1/2 x 13, 68–85	5/8 x 18, 136–170	
Master Cylinder or Booster Push Rod to Brake Pedal (500–900 Series)	3/8 x 16, 12–17		
Master Cylinder to Dash Panel (500–900 Series)	5/16 x 18, 12–17	3/8 x 16, 31–42	
Master Cylinder to Booster (Dash Mounted Booster) (500–700 Series)	14–18		
Booster to Dash Panel (Dash Mounted Booster) (500–700 Series)	3/8 x 16, 12–17	3/8 x 24, 13–20	5/16 x 18, 12–15
Master Cylinder to Pedal Bracket	5/16 x 24, 12–15	3/8 x 24, 12–17	
Eccentric Adjuster Bolt Torque	80–120 inch lbs.		

TORQUE LIMITS – HYDRAULIC TUBE NUTS (FT-LBS)

Thread Size	Ft-Lbs. ①	Thread Size	Ft-Lbs. ①
3/8–24	8–15	1/2–20	12–17
7/16–24	12–17	9/16–18	15–25

① All hydraulic line connections (nuts) must be torqued to the specified value and free of fluid leakage.

BRAKE DRUM REPAIR LIMITS (BRAKE LATHE)

Brake drums are marked with the maximum allowable braking surface diameter. If this diameter is exceeded by wear or refinishing, the drum must be replaced.

CH 1878-A

PART 12-05 Drum Brakes — Single Cylinder, Single Piston

Applies to P-500 And B-, LN-Series Trucks with 6000-7000 Lb. Axles

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BRAKE DRUMS		Removal and Installation	05-01

BRAKE BACKING PLATE		Disassembly and Assembly	05-03
Removal and Installation	05-02	Removal and Installation	05-02
BRAKE SHOES			
Adjustment	05-01		

ADJUSTMENTS

BRAKE SHOE ADJUSTMENT

The brake drums should be at normal room temperature, when the brake shoes are adjusted. If the shoes are adjusted when the shoes are hot and expanded, the shoes may drag as the drums cool and contract.

A brake adjustment re-establishes the brake lining-to-drum clearance and compensates for normal lining wear.

FRONT BRAKE

Manual Adjustment

The single anchor brake is adjusted by turning an adjusting screw located between the lower ends of the shoes.

1. Raise the vehicle until the wheels clear the floor.
2. Remove the cover from the adjusting hole at the bottom of the brake carrier plate, and turn the adjusting screw inside the hole to expand the brake shoes until they drag against the brake drum and lock up the drum. Back off the adjusting screw until a slight drag is noted (Fig. 1).

H1006-B

FIG. 1 Single Anchor Brake Shoe Adjustment

3. When the shoes are against the drum, back off the adjusting screw 10 to 12 notches so that the drum rotates freely without drag. If the drum does not rotate freely, remove the wheel and drum, and then blow out the dust and dirt from the linings. With sandpaper, remove all rust from the points where the shoes contact the carrier plate and apply a light coating of high temperature grease (C1AZ-19590-B). Be careful not to get the lubricant on the linings.
4. Install the wheel and drum, and adjust the shoes. Install the adjusting hole cover on the brake backing plate.
5. Check and adjust the other three brake assemblies.
6. Apply the brakes. If the pedal travels more than halfway down between the released position and the floor, too much clearance exists between the brake shoes and the drums. Repeat steps 2 and 3 above.
7. When all brake shoes have been properly adjusted, lower the vehicle. Road test the vehicle and check the operation of the brakes. Perform the road test only when the brakes will apply and the vehicle can be safely stopped.

REMOVAL AND INSTALLATION

BRAKE DRUMS

Since the brake drum service procedures for these models apply to both hydraulic and air brakes, they are covered under Adjustments in Part 12-01.

BRAKE SHOE AND ADJUSTING SCREW

Removal

Refer to Figure 2.

1. Raise the truck until the wheels clear the floor. Then remove the wheel and drum. **Do not push down the brake pedal after the brake drum has been removed.**
2. Clamp the brake cylinder boot against the end of the cylinder, and remove the brake shoe retracting springs from both shoes.

3. Remove the anchor pin plate (Fig. 2).
4. Remove the hold-down spring cups and springs from the shoes, and remove the shoes and the adjusting screw parts from the carrier plate. **Do not let oil or grease touch the brake linings.**
5. Remove the hold-down spring pins from the carrier plate.
6. Remove the adjusting screw parts from the brake shoes.

Installation

1. Coat all points of contact between the brake shoes and the other brake assembly parts with Lubriplate or similar lubricant. Lubricate the adjusting screw threads.
2. Place the adjusting screw, socket, and nut on the brake shoes so that the star wheel on the screw is opposite the adjusting hole in the carrier plate. Then install the adjusting screw spring.
3. Position the brake shoes and the adjusting screw parts on the carrier plate, and install the hold-down spring pins, springs, and cups.
4. Install the anchor pin plate on the pin.
5. Install the brake shoe retracting springs on both shoes, being careful not to bend the hooks or to stretch the springs beyond the attaching points. **The primary shoe spring must be installed first.**
6. Remove the clamp from the brake cylinder boot.
7. Install the wheel and drum.
8. Adjust the brakes, check the brake pedal operation, and lower the truck.

BRAKE WHEEL CYLINDER

Removal

1. Remove the wheel, drum, and brake shoes. Remove the cylinder-to-shoe connecting links.
2. Disconnect the brake line from the brake cylinder.
3. Remove the brake cylinder retaining bolts and lockwashers, and then remove the cylinder from the backing plate.

Installation

1. Position the brake cylinder on the backing plate and install the retaining bolts and lockwashers.
2. Install a new gasket on the brake line fitting and connect the line to the brake cylinder.
3. Install the brake shoes and the connecting links between the shoes and cylinder. Install the drum and the wheel.

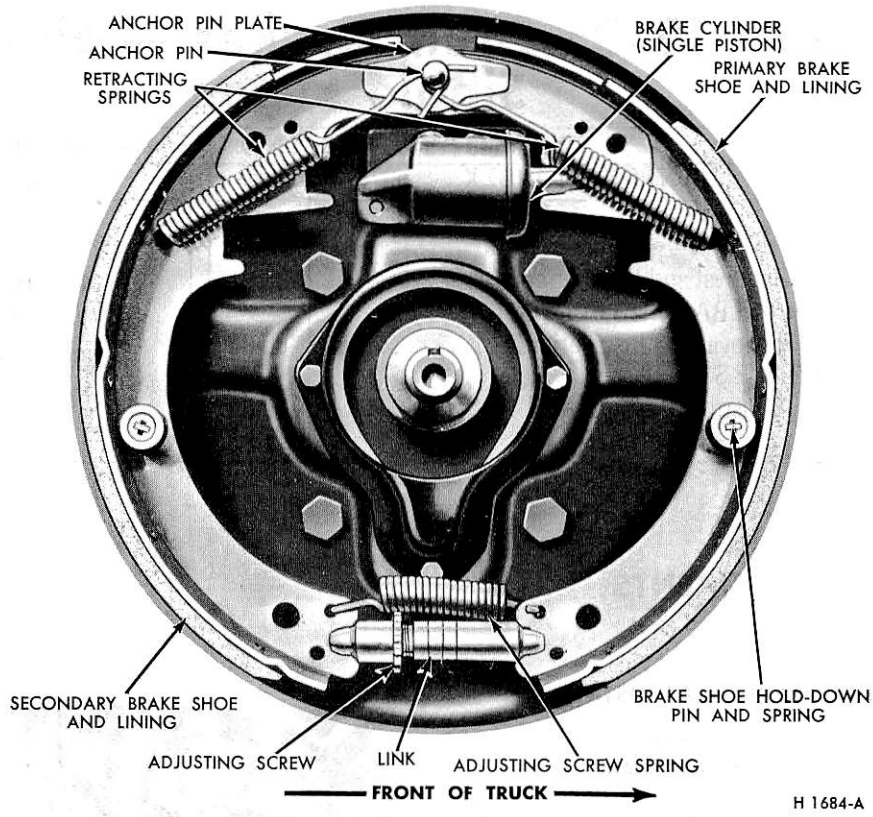

FIG. 2 Single Anchor Brake Shoe—Front—P-500

4. Adjust the brakes and bleed the system. Check the pedal operation before moving the vehicle.

BRAKE BACKING PLATE

Removal

1. From front wheel spindles, remove the hub and drum attaching parts (grease cap and gasket if so equipped, cotter pin, bearing adjusting nut and flat washer). Then, remove the outer wheel bearing and the hub and drum assembly from the spindle.
2. Remove the brake shoes and adjusting screw from the backing plate as outlined in this Section. Disconnect the brake line from the brake cylinder and submerge the end of the brake line in a can containing a small amount of brake fluid. This will minimize hydraulic line bleeding.
3. Remove the backing plate retaining bolts and nuts, then remove the backing plate from the front wheel spindle.
4. Remove the attaching bolts and lockwashers, and the brake cylinder from the backing plate.

Installation

1. Assemble the brake cylinder to the backing plate with the attaching bolts and lockwashers.
2. Mount the backing plate to the front wheel spindle and secure with the attaching bolts and nuts.
3. Install the brake shoes and adjusting screw to the backing plate as outlined in this Section. Connect the brake line to the brake cylinder.
4. Install a front wheel hub and drum assembly and the outer wheel bearing to the spindle. Install the hub and drum attaching parts (flat washer, bearing adjusting nut, cotter pin, grease cap, and gasket if so equipped). Adjust the front wheel bearings as outlined in Group 11.
5. Install the wheel and tire.
6. Bleed the hydraulic system and adjust the brake shoes.

MAJOR REPAIR OPERATIONS

BRAKE WHEEL CYLINDER

Disassembly

1. With the wheel cylinder removed, remove the rubber boot from the end of the brake cylinder. Remove the piston, cup, and piston return spring from the cylinder (Fig. 3).
2. Remove the bleeder screw from the cylinder.

Assembly

1. Coat all brake cylinder parts with clean extra heavy duty brake fluid C6AZ-19542-A.

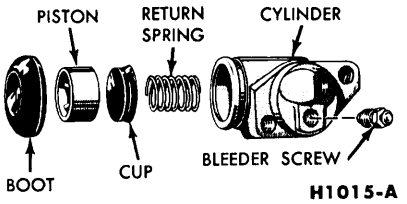

FIG. 3 Single Servo Brake Cylinder—Disassembled

2. Install the bleeder screw (Fig. 3) in the brake cylinder.
3. Place the piston return spring, cup, and piston in the cylinder bore, and install a boot and link over each end of the cylinder, clamp the brake cylinder piston against the end of the cylinder. **When a brake cylinder repair kit is used, install all of the parts supplied in the kit.**

PART 12-08 Drum Brakes — Dual Cylinders, Dual Pistons

Applies to 500 thru 900 Series Trucks

ADJUSTMENTS

BRAKE SHOE ADJUSTMENT

The brake drums should be at normal room temperature, when the brake shoes are adjusted. If the shoes are adjusted when the shoes are hot and expanded, the shoes may drag as the drums cool and contract.

A brake adjustment re-establishes the brake lining-to-drum clearance and compensates for normal lining wear.

Adjustment procedures for each type of brake assembly are given under the applicable heading.

REAR BRAKE — P-500 SERIES

The two-cylinder brake assembly brake shoes are adjusted by turning adjusting wheels reached through slots in the backing plate.

The brake adjustment is made with the vehicle raised. Check the brake drag by rotating the drum in the direction of forward rotation as the adjustment is made.

1. Remove the adjusting slot covers from the backing plate (Fig. 1).
2. Turn the rear (secondary shoe) adjusting screw inside the hole to expand the brake shoe until it drags against the brake drum.
3. Back off the adjusting screw so that the drum rotates freely without drag. Depress the brake pedal to center the brake shoes, and back off the adjusting screw an additional notch to provide operating clearance.
4. Repeat the above procedure on the front (primary) brake shoe.
5. Replace the adjusting hole covers.

SELF ADJUSTING BRAKES — REAR — 500-900 SERIES (EXCEPT P-500)

The brake shoes are automatically adjusted when the vehicle is driven in reverse and the brakes applied. A manual adjustment is required only after the brake shoes have been relined or replaced.

The two-cylinder brake assembly (Figs. 2 and 3) brake shoes are adjusted by turning adjusting wheels reached through slots in the backing plate.

Two types of two-cylinder brake assemblies are used on truck rear wheels. The assemblies differ primarily in the retracting spring hookup, and in the design of the adjusting screws and locks. However, the service procedures are the same for both assemblies.

The brake adjustment is made with the vehicle raised. Check the brake drag by rotating the drum in the direction of forward rotation as the adjustment is made.

1. Remove the adjusting slot covers from the backing plate (Fig. 1).
2. Turn the rear (secondary shoe) adjusting screw inside the hole to expand the brake shoe until a slight drag is felt against the brake drum.
3. Repeat the above procedure on the front (primary) brake shoe.
4. Replace the adjusting hole covers.
5. Complete the adjustment by applying the brakes several times while backing the vehicle.
6. After the brake shoes have been properly adjusted, check the operation of the brakes by making several stops while operating in a forward direction.

If a brake drum will not come off, remove the adjusting slot covers and back off the adjuster screws to free the drum from the shoes.

HYDRAULIC SYSTEM BLEEDING

Refer to Part 12-01 (General Hydraulic Brake Service) for hydraulic system bleeding procedures.

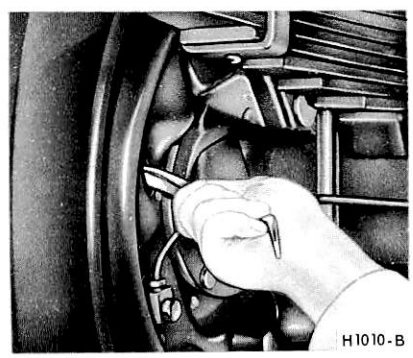

FIG. 1 Two-Cylinder Brake (Rear) Shoe Adjustment

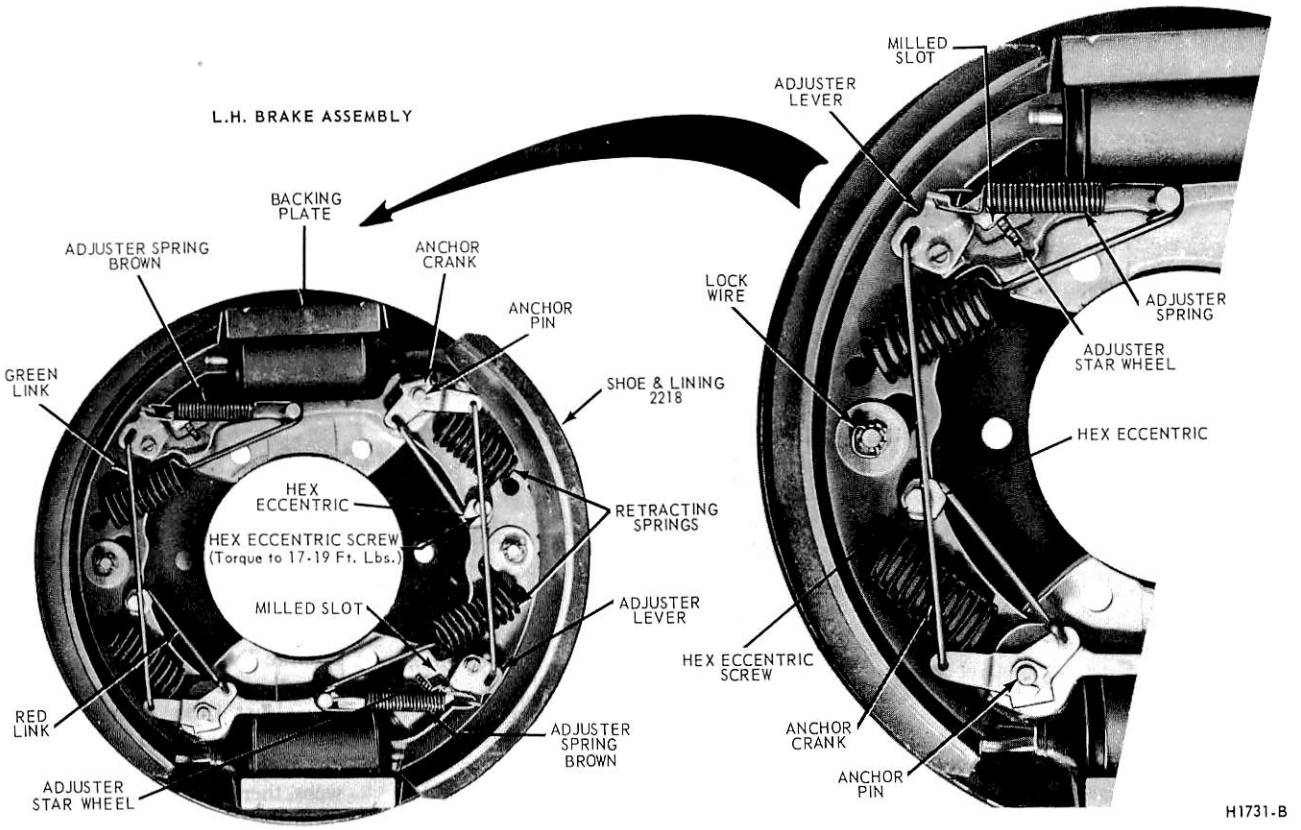

FIG. 2 Two-Cylinder Brake Shoe (Wagner) — Rear

REMOVAL AND INSTALLATION

BRAKE SHOES AND ADJUSTING SCREW

P-500 SERIES — REAR

Removal

Refer to Figure 4.

1. Raise the truck until the wheels clear the floor. Remove the wheel, and then remove the drum or the hub and drum assembly. **Mark the hub and drum to aid assembly in the same position.**
2. Clamp the brake cylinder boots against the ends of the cylinder and remove the four brake shoe retracting springs.
3. Remove the brake shoe guide bolt cotter pin, nut, washer, and bolt from both shoes and remove the shoes from the backing plate.
4. Remove the clamp-type adjusting wheel lock from the anchor pin support, and unthread the adjusting screw and wheel assembly from the anchor pin support.

Installation

1. Coat all points of contact between the brake shoes and other brake assembly parts with high temperature grease (C1AZ-19590-B).
2. Thread the adjusting screw and wheel assembly into the anchor pin support and install the clamp-type adjusting wheel lock. Thread the adjusting wheel into the support so that the brake shoe will rest against the adjusting wheel end.
3. Place the brake shoe against the backing plate, insert the ends in the brake cylinder links, and install the shoe guide bolt, washer and nut (Fig. 4). Finger tighten the nut, then back off one full turn, and install the cotter pin.
4. Install the four retracting springs with the tool shown in Fig. 5.
5. Remove the cylinder clamps, install the drum or the hub and drum assembly, then install the wheel assembly. **Align the marks on the hub and drum during installation.**
6. Adjust the brakes, and lower the truck.

600-900 SERIES—REAR—WAGNER

Removal

1. Raise the truck until the wheels clear the floor. Remove the wheel, and then remove the drum or the hub and drum assembly. It may be necessary to back off the adjusting wheels slightly to free grooved drums. Take care not to back off adjustment so much that adjusting wheel is jammed against the friction ring on the adjuster screw as this may damage the ring.

Mark the hub and drum to aid assembly in the same position. Be sure the engine is stopped and there is no vacuum in the system before disconnecting the hydraulic lines.

2. Unhook the two automatic adjuster springs (Fig. 2). Remove each long adjuster link by pivoting back the adjusting wheel cranks until their

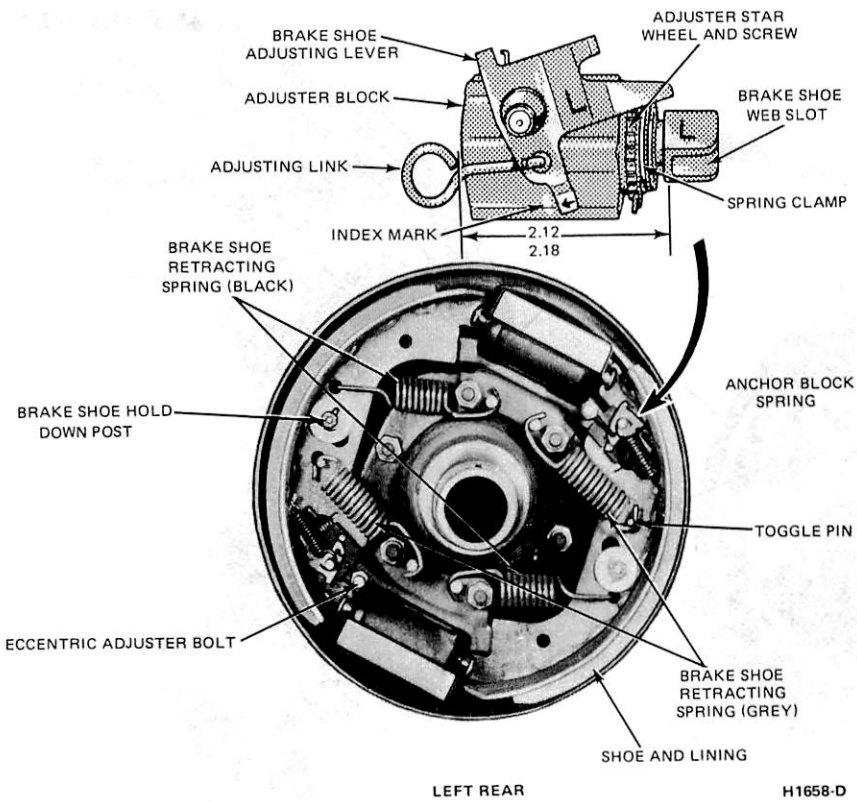

FIG. 3 Hydraulic Brake Assembly (Kelsey-Hayes)

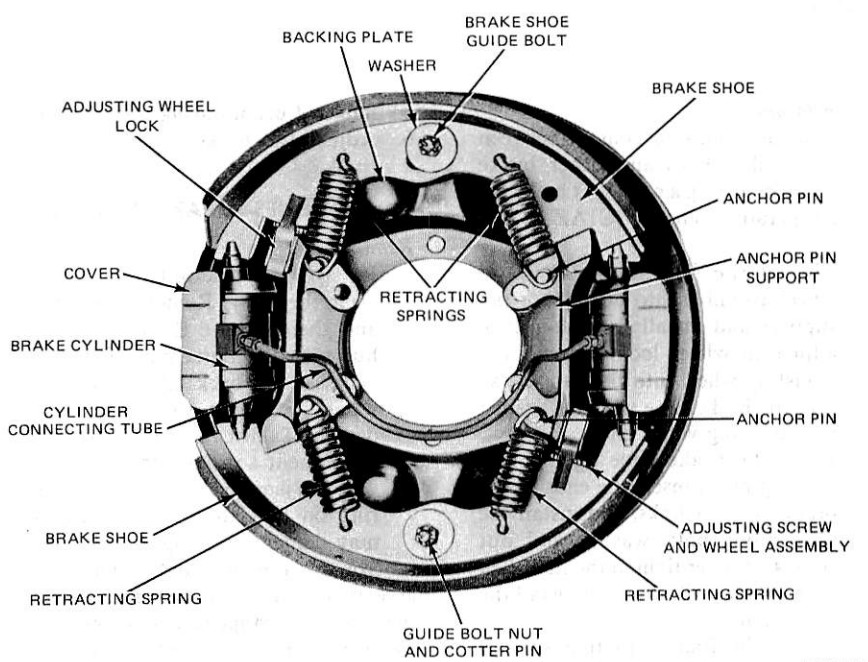

FIG. 4 Two Cylinder Brake—Rear—P-500

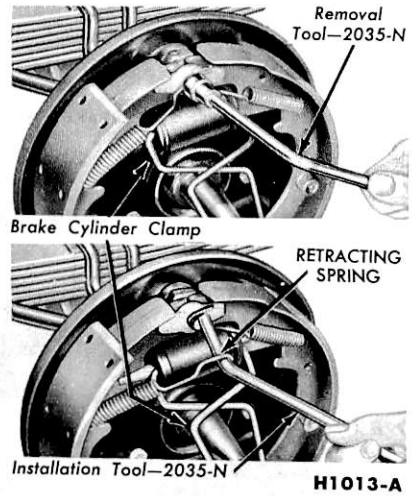

FIG. 5 Retracting Spring Replacement — Typical

slots align with the link hooks. Lift out the links, then slide the hooks from the anchor pin cranks. Remove the short links by rotating the anchor cranks until the link hooks clear the eccentrics on the shoe webs, then remove the smaller hooks from the cranks.

3. Spread the anchor crank C-washers and remove the cranks (it is usually unnecessary to remove the adjusting wheel cranks). If shoes are to be relined, remove adjuster eccentrics from the shoe webs by unscrewing their self-tapping screws.
4. Remove the shoe retraction springs by sliding the looped ends off the pins. Remove the shoe hold-down lock wires, castellated nuts and plain washers and lift the shoes off the backing plate.
5. Unthread the adjusting screw and adjusting wheel from each of the anchor supports.

Installation

1. Insert the adjusting wheels in the anchor support slots and thread in the adjuster screws from the shoe side, friction ring end toward the shoe. For new linings, back off adjusters, taking care not to jam the adjusting wheels. Do not lubricate adjuster screws.
2. Position the shoes (Fig. 2) to the backing plate. Locate shoe with its toe (cutaway portion of web) positioned in the adjuster slot, heel in the anchor pin slot. Install hold-down bolt, plain washer and castellated nut finger tight, then back off nut one turn and install the lockwire.

3. Install the retracting springs in the shoe web, longest end at the adjuster, and hook the springs over the pins.
4. On each shoe web, install the adjuster hex eccentric, tightening the self-tapping screw finger-tight to permit final adjustment of the eccentrics.
5. Position the anchor cranks on the anchor pins with the long end toward the shoes. Install and crimp the C-washers.
6. At each crank, install the short link with the small hook end into the short arm of the crank. Install the other link end around the eccentric on the shoe web.
7. Install the long link S-hook end to the long arm of the crank. Rotate the adjusting wheel crank so that slot lines up with link U-hook end and insert the hook. Rotate the adjusting wheel crank back to the approximate adjusting position.
8. Install the adjuster spring with the short end on the adjusting wheel crank finger and the long end on the upper groove of the spring retainer pin. Center the brake shoe assemblies to the backing plate.
9. Lift the adjuster lever up and away from the star wheel. Then loosen the hex eccentric screw and rotate each hex eccentric until the adjuster lever aligns the adjusting wheel crank pawl with the center line of the adjusting screws. **A milled slot located on the anchor support is the aligning mark.** With the eccentrics adjusted, tighten the self-tapping screws.
10. Install the drum or the hub and drum assembly, then install the wheel assembly. Align the marks on the hub and drum during installation.
11. Bleed the brake system and adjust the brakes. Lower the vehicle.

500-800 SERIES (EXCEPT P-500) — REAR — KELSEY HAYES

Removal

Refer to Figure 3.

1. Raise the truck until the wheel clears the floor.
2. Remove the wheel, hub and drum assembly. Refer to Part 12-01.
3. Clamp the brake cylinder boots against the ends of the cylinder with brake piston clamps.
4. **Note the two different types of brake shoe retracting springs and remove the springs.**
5. Remove the brake shoe hold down post cotter key, nut, and shoe hold down washer.
6. Loosen and remove the eccentric adjuster bolt, lock washer, eccentric and adjusting link.
7. Remove the shoe and lining assembly from the backing plate.
8. Remove the anchor block spring and slide the adjuster assembly from the shoe web.
9. Remove the adjuster star wheel and screw from the adjuster block. Unthread the star wheel from the adjuster screw.

Installation

Refer to Figure 3.

1. Wipe all brake dust from the brake assembly parts with a **clean dry rag. Coat all points of contact between brake shoes and other parts with high temperature grease (C1AZ-19590-B or E).**
2. Coat the adjuster screw and the inside of the adjuster block with high temperature grease (C1AZ-19590-B or E).
3. Thread the adjuster screw onto the star wheel and insert the adjuster screw assembly into the adjuster block. Maintain a 2.12-2.18 inch dimension from the end of the adjuster block to the adjuster screw web slot.
4. Install the adjuster assembly onto the shoe web and attach the anchor block spring.
5. Place the brake shoe over the retracting spring toggle pin and insert the ends of the shoe in the wheel cylinder links.
6. Install the shoe hold down washer and nut. Do not install the cotter pin.
7. Install the four brake shoe retracting springs. Make sure the retracting springs are installed as shown in Fig. 3. On 15 x 5 inch brakes the inner hook ends face the wheel cylinders. On 15 x 4 inch brakes the inner hook ends face the center of the axle.
8. Install the adjusting link, eccentric, lockwasher and adjuster bolt. Do not tighten.
9. Remove the brake piston clamps.
10. Tighten the shoe hold down nut until there is 0.015-0.025 inch clearance between the shoe and hold down washer with the shoe held against the backing plate. Install the cotter pin.
11. Center the shoes on the backing plate. Using a 1/2 inch wrench, rotate the adjuster eccentric until the adjusting lever is at the index mark (Fig. 3). Tighten the eccentric adjuster bolt to specification.
12. Install the wheel, hub and drum assembly.
13. Adjust the brake to obtain a slight drag. Subsequent adjustments will be automatic.

BRAKE WHEEL CYLINDER

Removal

1. Remove the wheel, drum, and brake shoes. Remove the cylinder-to-shoe connecting links.
2. Disconnect the brake lines from the brake cylinders.
3. Remove the brake cylinder retaining bolts and lockwashers, and then remove the cylinder from the backing plate. On the two-cylinder brake assemblies, remove the cover with the brake cylinder.

Installation

1. Position the brake cylinder on the backing plate and install the retaining bolts and lockwashers. Torque the retaining bolts to 150-200 in-lbs. On the two-cylinder brake assemblies, install the cover with the brake cylinder.
2. Install a new gasket on the brake line fitting and connect the line to the brake cylinder.
3. Install the brake shoes and the connecting links between the shoes and cylinder. Install the drum and the wheel.
4. Adjust the brakes and bleed the system. Check the pedal operation before moving the vehicle.

BRAKE BACKING PLATE

300 THROUGH 900 SERIES

Removal

1. From front wheel spindles, remove the hub and drum attaching parts (axles under 9,000 lbs capacity-grease cap and gasket if so equipped, cotter pin, bearing adjusting nut and flat washer) (Axles 9,000 lbs capacity or over-grease cap and gasket, lock nut, dimpled washer, locking ring, and bearing adjusting nut and pin assembly.) Then, remove the outer wheel bearing and the hub and drum assembly from the spindle.
2. On rear wheels, remove the rear axle shaft flange retaining nuts and axle shaft. Remove the rear wheel bearing lock nut, lock washer, and adjusting nut, then remove the hub and drum assembly from the axle housing. Discard the grease seal.
3. Remove the brake shoes and adjusting screw from the backing plate as outlined in this section. Disconnect the brake line from the brake cylinder and submerge the end of the brake line in a can containing

a small amount of brake fluid. This will minimize hydraulic line bleeding.
4. Remove the backing plate retaining bolts and nuts, then remove the backing plate from the front wheel spindle or rear axle housing.
5. Remove the attaching bolts and lock washers, and the brake cylinder from the backing plate.

Installation

1. Assemble the brake cylinder to the backing plate with the attaching bolts and lockwashers.
2. Mount the backing plate to the front wheel spindle or to the rear axle housing flange, and secure with the attaching bolts and nuts.
3. Install the brake shoes and adjusting screw to the backing plate as outlined in this section. Connect the brake line to the brake cylinder.
4. Install a front wheel hub and drum assembly and the outer wheel bearing to the spindle. Install the hub and drum attaching parts (axles under 9,000 lbs capacity-flat washer, bearing adjusting nut, cotter pin, grease cap, and gasket if so equipped, axles 9,000 lbs. capacity or over-bearing adjusting nut and pin assembly, locking ring, dimpled washer, lock nut, and grease cap and gasket). Adjust the front wheel bearings as outlined in Group 11.

Install a rear wheel hub and drum assembly on the rear axle housing. **The rear hub oil seal must be replaced whenever a hub is removed or installed.** Install the outer bearing and the adjusting nut, then adjust the wheel bearings. Install the lock washer and lock nut, then torque to specifications. Install the rear axle shaft, gasket and attaching nuts, then torque to specifications.

5. Install the wheel and tire.
6. Bleed the hydraulic system and adjust the brake shoes.

BRAKE MASTER CYLINDER

500-600 SERIES—POWER BRAKE—DASH MOUNTED BOOSTER

Removal

1. With the engine stopped, depress the brake pedal to expell vacuum from the brake booster system.
2. Disconnect the hydraulic lines from the brake master cylinder.
3. Remove the brake booster to master cylinder retaining nuts and lockwashers. Remove the master cylinder from the brake booster.

Installation

1. Before installing the master cylinder, check the distance from the outer end of the booster assembly push rod to front face of the brake booster assembly. Turn the push rod adjusting screw in or out as required to obtain the specified length (Fig. 6).
2. Position the master cylinder assembly over the booster push rod and onto the two studs on the booster assembly. Install the attaching nuts and lockwashers and torque them to specifications.
3. Connect the hydraulic brake system lines loosely to the master cylinder.
4. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this Section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with the specified C6AZ-19542-A brake fluid. Install the gasket (diaphragm) and filler cap.

F-500-750, C-600-900 SERIES—SINGLE-BRAKE SYSTEM

Removal

The engine must be stopped and all vacuum must be expelled from the booster system before the hydraulic lines are disconnected.

1. Disconnect the stoplight switch wires from the switch, and disconnect the brake line from the brake fitting.
2. Force as much brake fluid as possible from the master cylinder into a suitable container by pushing down the brake pedal all the way several times.
3. On a vehicle with a frame-mounted booster disconnect the rubber boot from the rear end of the master cylinder in the cab. Remove the bolts that hold the master cylinder against the dash panel, and lift the cylinder away from the push rod and out of the engine compartment.

On vehicles equipped with a dash-mounted booster, remove the nuts and washers that secure the master cylinder to the power booster unit, and remove the master cylinder.

Installation

1. On a vehicle with a frame-mounted booster, position the rubber boot on the piston push rod, guide the master cylinder over the end of the push rod and position the cylinder against the mounting surface. Install the mounting bolts and torque them to specifications.

On vehicles equipped with a dash-mounted booster, install the master cylinder over the push rod onto the two studs in the power booster body. Install the lockwashers and retaining nuts. Torque the nuts to specifications.

2. Connect the brake line to the master cylinder fitting, but leave the brake line fitting loose.
3. Fill the master cylinder reservoir with C6AZ-19542-A extra heavy duty brake fluid to within 1/4 inch of the top of the filler neck.
4. Push the brake pedal down slowly by hand several times to let air escape at the brake line fitting. Hold the pedal down and tighten the brake line fitting. Release the brake pedal. **Do not release the brake pedal until the fitting is tightened as additional air will be introduced into the master cylinder.**

On vehicles equipped with dash-mounted booster, the cylinder can be bled at the bleed screw on the cylinder.

On a vehicle with a frame-mounted brake booster assembly, the master cylinder can be bled at the booster bleed screw(s).

5. After seeing that the master cylinder reservoir is filled with the specified brake fluid to within 1/4 inch of the top of the filler neck, install the filler cap. Wipe off any fluid from the outside of the cylinder and brake line.
6. Connect the stoplight switch wires to the switch.
7. Connect the rubber boot to the end of the cylinder.
8. Check and, if necessary, adjust the brake pedal free-travel.

L-, LN-, AND B-SERIES SPLIT BRAKE SYSTEM AND FRAME MOUNTED BOOSTER

Removal

Refer to Figures 7 and 8.

1. Working from inside the vehicle below the instrument panel, disconnect the wires from the stop light switch.
2. On L-and LN-Series, remove the retaining nut, shoulder bolt, spacers and bushing securing the master cylinder push rod and the stop light switch to the brake pedal assembly. Remove the switch.

On B-Series, remove the hair pin clip from the brake pedal pin. Remove the push rod, spacers, stop light switch, and bushing from the brake pedal pin.

3. Remove the boot from the master cylinder push rod.
4. Disconnect the brake hydraulic system lines from the master cylinder.
5. Remove the master cylinder to dash panel retaining screws and remove the master cylinder.

Installation

1. Position the master cylinder assembly on the dash panel within

the engine compartment and install the retaining screws and washers. Tighten the screws to specification.
2. Connect the hydraulic brake system lines loosely to the master cylinder.
3. Lubricate the push rod bushing with lubricant (Lubriplate). Position the bushing in the push rod.
4. On L-and LN-Series, position the stop light switch on the push rod, install the shoulder bolt and spacers. **Make sure the bushings and spacers are installed properly.** Secure the push rod and stop light switch to the brake pedal assembly with the selflocking nut.

On B-Series, install the spacers, push rod, bushing and stop light switch on the brake pedal pin. Install the hair pin retainer.

5. Connect the wires to the stop light switch.
6. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this Section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with C6AZ-19542-A extra heavy duty brake fluid. Install the gasket (diaphragm) and filler cap.

P-500 SERIES

Removal

1. The engine must be stopped and all vacuum must be expelled from the booster system before the hydraulic lines are disconnected.
2. Turn the front wheels all the way to the left, and remove the fender apron attaching screws so that the apron can be moved to provide access to the master cylinder.
3. Disconnect the stoplight switch wires from the switch.
4. Disconnect the brake line from the brake tube fitting.
5. Force as much brake fluid as possible from the master cylinder into a suitable container by pushing down the brake pedal all the way several times.
6. Disconnect the rubber boot from the end of the master cylinder.
7. Remove the brake pedal return spring, remove the cotter pin from the clevis pin, and remove the master cylinder push rod and boot. Remove the three mounting bolts and remove the master cylinder from the mounting bracket and away from the vehicle.

Installation

1. Assemble the master cylinder to the mounting bracket and secure with the three mounting bolts. Install the push rod and boot to the front of the master cylinder. Connect the front end of the push rod to the upper holes of the brake pedal extension with the clevis pin, and secure with a cotter pin. Install the brake pedal retracting spring.
2. Connect the brake line to the master cylinder fitting, but leave the brake line fitting loose.
3. Fill the master cylinder with extra heavy-duty brake fluid C6AZ-19542-A to the specified level (1/4 inch from the top).
4. Push the brake pedal down slowly by hand several times to let air escape at the brake line fitting. Hold the pedal down and tighten the brake line fitting. Do not release the brake pedal until the fitting is tightened, as additional air will be introduced into the master cylinder. Repeat this procedure until air ceases to escape at the fitting and a firm pedal is obtained.
5. After seeing that the master cylinder reservoir is filled with the specified C6AZ-19542-A extra heavy duty brake fluid to within 1/4 inch of the top of the reservoir, install the filler cap. Wipe off the fluid from the outside of the cylinder and brake line.
6. Connect the stoplight switch wires to the switch.
7. Connect the rubber boot to the end of the cylinder. Reposition the fender apron and secure with the five retaining bolts.
8. Check and, if necessary, adjust the brake pedal free travel.

C-SERIES SINGLE BRAKE SYSTEM

Removal

The engine must be stopped and all vacuum must be expelled from the booster system before the hydraulic lines are disconnected.

1. Roll back the floor mat, remove the floor plate, and then disconnect the hydraulic line from the master cylinder.
2. Force as much brake fluid as possible from the master cylinder into a suitable container by pushing down the brake pedal all the way several times.
3. Disconnect the rubber boot from the rear end of the master cylinder in the cab.
4. Remove the two mounting bolts and lower the master cylinder away from the push rod and out of the cab.

Installation

1. With the rubber boot on the piston push rod, guide the master cylinder over the end of the push rod, and position the cylinder against the mounting surface. Install the mounting bolts, and torque them to specifications.
2. Connect the brake line to the master cylinder fitting and tighten the fitting.
3. Fill the master cylinder reservoir with the specified brake fluid to within 1/4 inch of the top of the filler neck.
4. Bleed the brake system.
5. After seeing that the master cylinder reservoir is filled with the specified C6AZ-19542-A extra heavy duty brake fluid to within 1/4 inch of the top of the filler neck, install the filler cap. Wipe off any fluid from the outside of the cylinder and brake line.
6. Connect the rubber boot to the end of the cylinder. Install the floor plate and secure with the seven retaining screws, and place the floor mat in its proper position.
7. Check and, if necessary, adjust the brake pedal free-travel.

C-SERIES — SPLIT BRAKE SYSTEM

Removal

Refer to Figure 9.

All vacuum must be relieved from the booster before hydraulic lines are disconnected.

1. Disconnect the hydraulic lines from the master cylinder. Trap the fluid drip with a shop towel or plug the ports.
2. Remove the bolt and nut connecting the push rod to the brake pedal bell crank and remove the stop light switch, bushing and spacers.
3. Remove the master cylinder mounting bolts and remove the master cylinder from the vehicle.

Installation

Refer to Figure 9.

1. If the master cylinder is being replaced, transfer the outlet ports to the new master cylinder.
2. Position the master cylinder to the dash panel and install the mounting bolts.
3. Assemble the stop light switch, bushing and spacers on the push rod and install the bolt connecting the push rod to the bell crank.
4. Connect the primary and secondary outlet tubes and tighten to specifications.
5. Bleed the brake system.

DUAL BRAKE MASTER CYLINDER PRESSURE DIFFERENTIAL VALVE ASSEMBLY

Removal

1. Raise the vehicle on a hoist. Disconnect the brake warning light wire from the pressure differential

valve assembly switch. **To prevent damage to the brake warning switch wire connector, expand the plastic lugs to allow removal of the shell-wire connector from the switch body.**
2. Disconnect the brake hydraulic lines from the differential valve assembly.
3. Remove the screw retaining the pressure differential valve assembly to the frame side rail and remove the valve assembly.
4. **If the differential valve is to be replaced, remove the brake warning lamp switch and install the switch in the new differential valve. The pressure differential valve assembly and the brake warning lamp switch are separate units and each is serviced as a separate assembly only.**

Installation

1. Mount the pressure differential valve assembly on the frame side rail and tighten the attaching screw.
2. Connect the brake hydraulic system lines to the differential valve assembly and tighten the tube nuts securely.
3. Connect the shell-wire connector to the brake warning lamp switch. **Make sure the plastic lugs on the connector hold the connector securely to the switch.**
4. Bleed the brakes and centralize the pressure differential valve as outlined in this Section of the manual.

BRAKE PEDAL ASSEMBLY

L-, LN-, AND LT-SERIES

Removal

1. Remove the brake pedal retracting spring (Fig. 7).
2. Remove the brake master cylinder push rod eccentric bolt nut, and remove the bolt and two nylon bushings.
3. Remove the nut from the pedal shaft. Then slide the shaft to the left and remove the brake pedal and sleeve.
4. Remove the two bushings from the pedal, and remove the bumper from the pedal extension bracket if so equipped.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Install the bumper on the pedal extension bracket (if so equipped), and position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly and sleeve in the pedal support bracket. Slide the pedal shaft through the sleeve and pedal and secure with the nut. Torque the nut to specifications.
4. Position the nylon bushings in the bore of the push rod. Connect the push rod to the brake pedal with the eccentric bolt and nut. Install the pedal retracting spring.
5. Adjust the brake pedal free travel to 3/16-3/8-inch (Fig. 11, Part 12-01). Torque the eccentric bolt nut to specifications.

P-500 SERIES

Removal

1. Open the front cover and disconnect the transmission gearshift rods from the shaft levers. Set the rods so that the maximum working space is obtained at the pedal support bracket.
2. Remove the pedal pads from the clutch and brake pedal (Fig. 10).
3. Remove the eight screws that retain the two floor covers at the steering column, and remove the covers. Unlatch the engine cover assembly and open.
4. Remove the eight floor plate retaining screws. Pull the accelerator pedal from the accelerator linkage and remove the floor plate.
5. Disconnect the clutch and brake pedal retracting springs.
6. Loosen the pedal support bracket clamp bolt. Remove the cotter pins and clevis pins from the clutch and brake pedals.
7. Turn the front wheels full left. Through the left front fender apron, remove the locking pin from the clutch pedal and remove the pedal. Push the pedal shaft toward the centerline of the vehicle. From inside the cab, slide the pedal shaft and clutch pedal lever to the right and out of the support bracket. Remove the brake pedal from the support bracket, then remove the bushings from the pedal and the pedal support bracket.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant. Install new bushings in the pedal support bracket and the brake pedal.
2. Position the brake pedal in the support bracket, and slide the pedal shaft and clutch pedal lever through the bracket and pedal.
3. Through the left front fender apron, install the clutch pedal on the shaft and secure it with a new locking pin.
4. Position the clutch rod on the clutch pedal lever, install the clevis pin and secure it with a new cotter pin.
5. Position the brake master cylinder push rod in the brake pedal, install the clevis pin and secure it with a new cotter pin.
6. Install the clutch and brake pedal retracting springs.
7. Adjust the brake pedal by removing the clevis pin from the master cylinder push rod and turning the hex head of the push rod until the specified free travel is obtained.

B-SERIES

Removal

1. Remove the brake pedal retracting spring (Fig. 8).
2. Remove the clevis pin retaining clip and remove the pin, spacers, master cylinder push rod bushing and switch assembly.
3. Remove the clip from the pedal shaft. Then slide the shaft to the left and remove the brake pedal.
4. Remove the two bushings from the pedal.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly in the pedal support bracket. Slide the pedal shaft through the pedal and secure with the retaining clip.
4. Position the nylon bushing in the bore of the push rod. Connect the push rod, switch assembly and spacers to the brake pedal with the clevis pin and secure with the retaining clip.
5. Install the pedal retracting spring.

C-SERIES

Removal

1. Remove the brake pedal retracting spring (Figs. 9 and 11).
2. Remove the brake master cylinder push rod eccentric bolt nut, bolt and nylon bushings.
3. Remove the brake pedal bumper-to-bracket retaining nut. Then remove the bolt and bumper.
4. On models with a single hydraulic brake system, remove the master cylinder push rod by pulling up on the tab on the push rod boot, and remove the push rod and boot from the cylinder.
5. Remove the nut from the bolt, slide the bolt to the right and remove the brake pedal assembly, sleeve and bushing.
6. Remove the bushings from the pedal assembly.

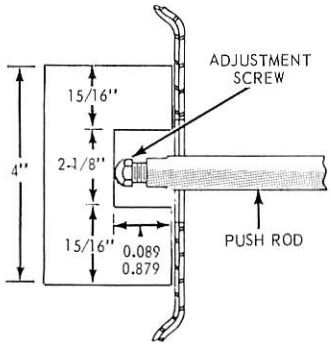

FIG. 6 Midland-Ross Booster Push Rod Gauge Dimensions and Adjustment

Installation

1. Coat all bushings and the pedal shaft, with a small quantity of Lubriplate or an equivalent lubricant. Position the nylon bushings in the brake pedal shaft bore.
2. Position the brake pedal assembly sleeve and bushing in the pedal support bracket, slide the bolt to the left and install the nut. Torque the nut to specifications.
3. On models with a single hydraulic brake system, install the push rod and boot in the master cylinder.
4. On models with a single hydraulic brake system, install the pedal bumper bolt, bumper and nut. Tighten the nut securely.
5. Install the two nylon bushings in the push rod bore, and install the push rod eccentric bolt and nut.
6. Install the pedal retracting spring.
7. On models with a single hydraulic brake system, adjust the brake pedal free-travel to 3/16-3/8 inch. Torque the eccentric bolt nut to specifications.

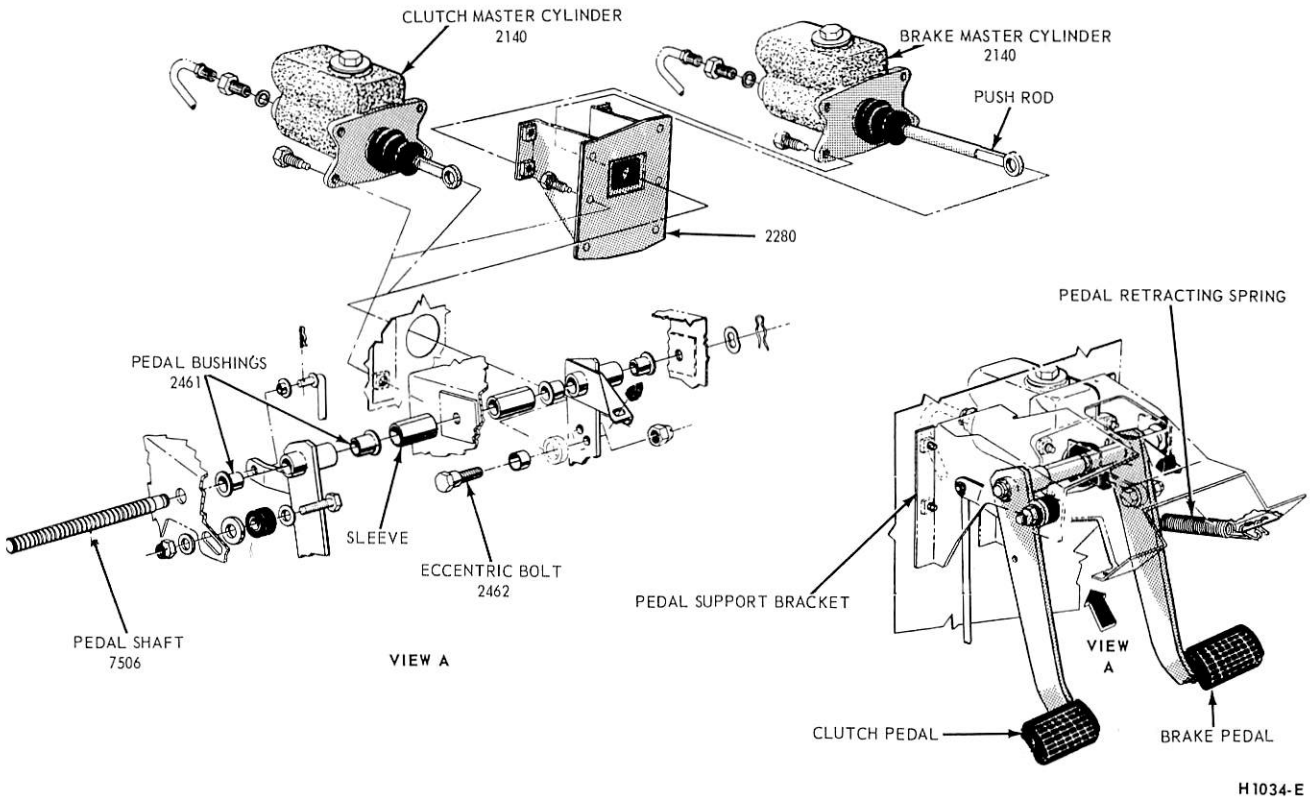

FIG. 7 L-, LN-, or LT-Series Brake Pedal and Related Parts

OVERHAUL

BRAKE WHEEL CYLINDER

Disassembly

1. With the wheel cylinder removed, remove the rubber boots from the ends of the brake cylinder. Remove the pistons, cups, and piston return spring from the cylinder (Fig. 12).
2. Remove the bleeder screw from the cylinder.

Assembly

1. Coat all brake cylinder parts with clean extra heavy duty brake fluid C6AZ-19542-A.
2. Install the bleeder screw (Fig. 12) in the brake cylinder.
3. Place the piston return spring, cups, and pistons in the cylinder bore, and install a boot and link over each end of the cylinder, clamp the brake cylinder pistons against the ends of the cylinder. **When a brake cylinder repair kit is used, install all of the parts supplied in the kit.**

MASTER CYLINDER

SINGLE BRAKE SYSTEM

Disassembly

1. With the master cylinder removed, clean the outside of the master cylinder, and remove the filler cap and gasket. Pour out any brake fluid that may remain in the cylinder and reservoir.

On a C-Series Truck master cylinder (Fig. 13), remove the 4 bolts that hold the cylinder body on the reservoir, and remove the gasket. Press down on the piston to compress the return spring, and remove the snap ring. Remove the piston, primary cup, piston filler, return spring, check valve, and check valve seat.

On vehicles equipped with a frame mounted vacuum brake booster, the check valve is installed in the booster instead of in the master cylinder.

2. On a L-, LN-, P-, or LT-Series truck master cylinder with a box-shaped reservoir, remove the fitting and gaskets from the forward end of the cylinder. Discard the gaskets. Remove the snap ring from the bore at the rear end of the cylinder, and remove the stop plate, piston cup, spring, check valve, and seat from the cylinder bore. If necessary, blow through the forward bolt hole to remove the parts.

Assembly

1. Dip all parts except the master cylinder body in clean hydraulic brake fluid. **Use only C6AZ-19542-A heavy duty brake fluid.**
2. On a L-, LN-, P-, LT-Series truck with a box-shaped master cylinder reservoir, install the brake fitting, bolt, and new gaskets on the forward end of the cylinder. Install the valve seat, valve, spring, cup, piston, and stop plate in the cylinder bore. Install the snap ring in the rear end of the bore.
3. On a C-Series truck master cylinder, install the valve seat, valve, spring, piston filler, cup and piston in the cylinder bore. Push down on the piston to compress the spring, and install the snap ring in the bore.

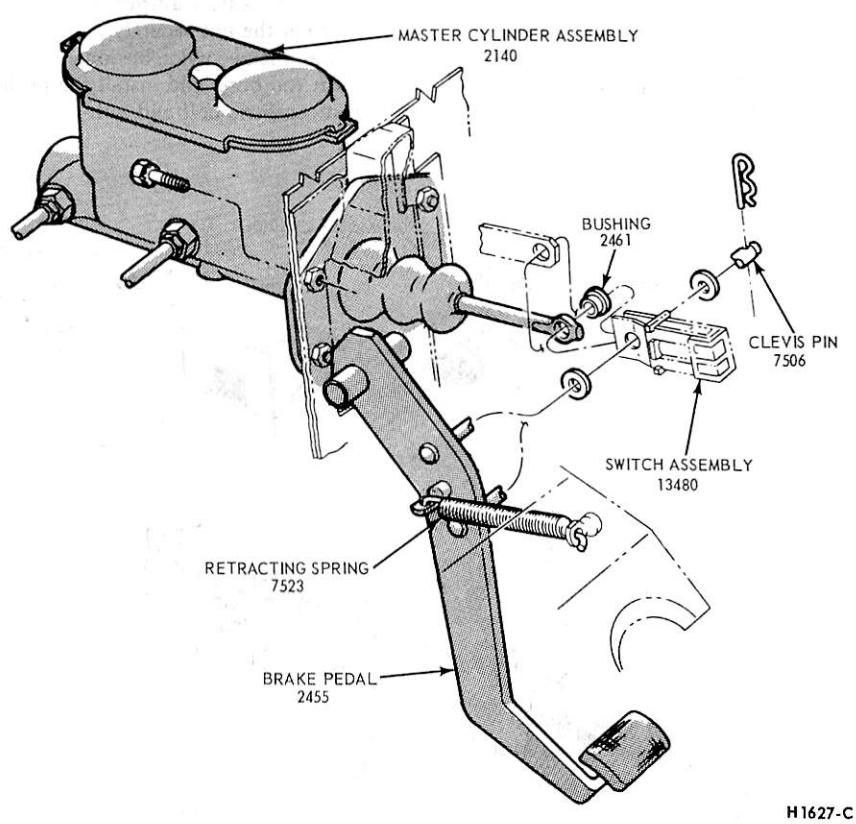

FIG. 8 B-Series Brake Pedal and Related Parts

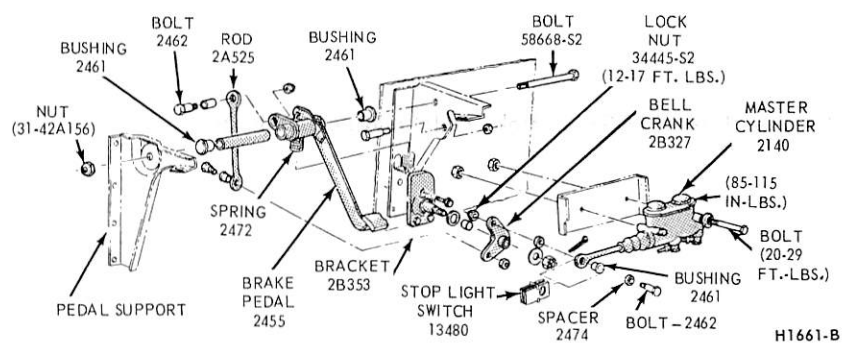

FIG. 9 Dual Master Cylinder and Brake Pedal Installation — C-Series

Position a new gasket over the cylinder body and mount the body to the reservoir. Secure with 4 bolts. Tighten bolts securely.

500-900 SERIES — SPLIT HYDRAULIC BRAKES AND FRAME MOUNTED BOOSTER

Disassembly

Refer to Figure 14.

1. Clean the outside of the master cylinder. Remove the cylinder cover screw. Lift off the cover and the diaphragm gasket and pour off excess brake fluid. Use the push rod to stroke the cylinder, forcing fluid from the cylinder through the outlet ports.
2. Loosen and remove the piston stop screw and gasket from the right hand side of the cylinder.
3. Pull back the push rod boot and remove the snap ring from the groove in the end of the cylinder bore.
4. Remove the push rod and stop plate from the master cylinder.
5. Remove the internal parts from the master cylinder. If the parts will not slide out loosely assemble the cover plate and seal the primary outlet port, then apply air pressure at the secondary outlet port.

Inspection and Repair

1. Clean all parts in isopropyl alcohol. Inspect the parts for chipping, excessive wear or damage. Replace them as required. **When using a master cylinder repair kit, install all the parts supplied.**
2. Check all recesses, openings and internal passages to be sure they are open and free of foreign matter. Passages may be probed with soft copper wire, 0.020 inch OD, or smaller.
3. Minor scratches or blemishes in the cylinder bore can be removed with crocus cloth or a clean up hone. Do not oversize the bore more than 0.007 inch.

Assembly

Refer to Figure 14.

1. Dip all parts except the master cylinder in clean extra heavy duty C6AZ-19542-A hydraulic brake fluid.
2. Install the rear rubber cup on the secondary piston with the cup lip facing the rear. All other cups face the front or closed end of the cylinder.
3. Assemble and install the secondary piston spring, front cup, and the secondary piston.
4. Install the piston stop screw and gasket, making sure the screw enters the cylinder behind the rear of the secondary piston.
5. Assemble and install the primary piston and push rod parts.
6. Locate the stop plate in the seat in the bore and engage the snap ring into the groove at the rear of the cylinder.
7. Install the push rod boot onto the push rod and the groove of the cylinder housing.
8. Bleed the master cylinder.

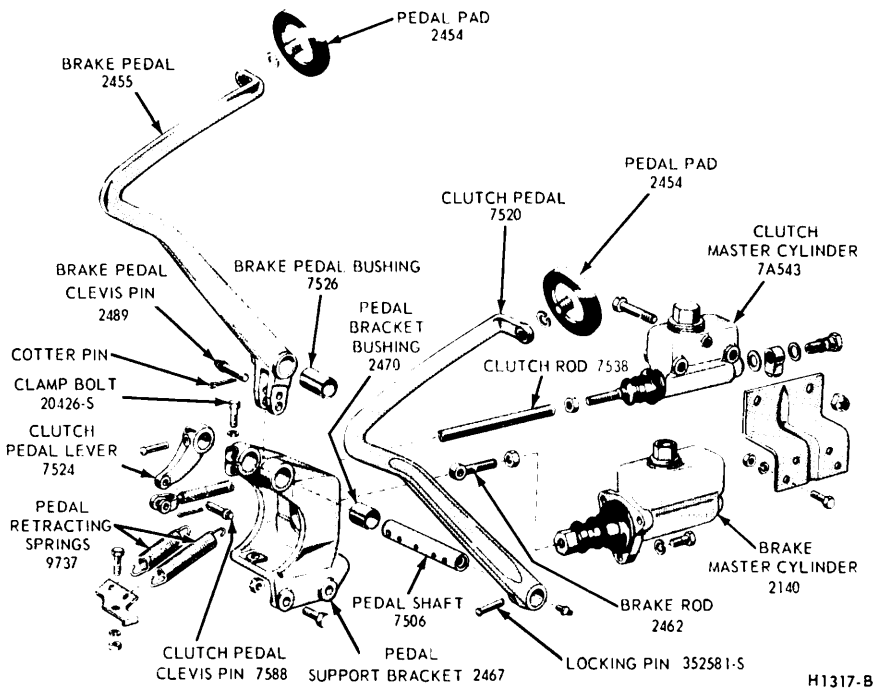

FIG. 10 Brake Pedal and Related Parts — P-500

Bleeding the Master Cylinder

Before the master cylinder is installed on the vehicle, the unit should be bled.

1. Support the master cylinder body in a vise, and fill both fluid reservoirs with C6AZ-19542-A extra heavy duty brake fluid.
2. Loosely install plugs in the front and rear brake outlet bores. Depress the primary piston several times until air bubbles cease to appear in the brake fluid.
3. Tighten the plugs and attempt to depress the piston. **The piston travel should be restricted after all air is expelled.**
4. Remove the plugs. Install the cover and diaphragm gasket assembly, and make sure the cover screw is tightened securely.

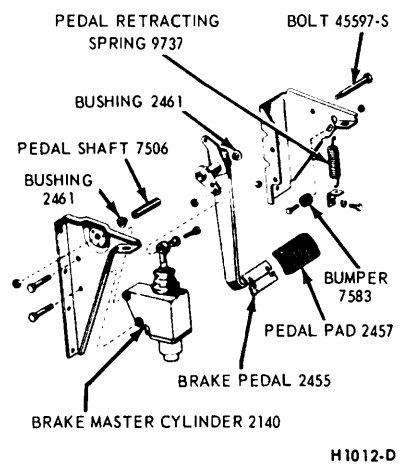

FIG. 11 Single Master Cylinder and Brake Pedal Installation — C-Series

L-AND LN-500-600 SERIES — SPLIT BRAKE SYSTEM AND DASH MOUNTED BOOSTER

Disassembly

Refer to Figure 15.

1. Clean the outside of the cylinder and remove the filler cap and gasket (diaphragm). Pour out any brake fluid that may remain in the reservoir. Stroke the push rod three

times to remove fluid from the cylinder bore.
2. Remove the reservoir retainers, washers, and reservoir from the master cylinder body.
3. Remove the two rubber washers from the reservoir and the two O-rings from the reservoir retainers.
4. Remove the snap ring, spring retainer and push rod spring.
5. Unscrew the retainer bushing counterclockwise and remove the push rod, retainer bushing, seal retainer and primary piston from the master cylinder.
6. Remove the primary piston from the push rod and discard it.
7. Remove the seal retainer, and retainer bushing from the push rod. Remove the two lip seals and the two O-rings from the retainer bushing.
8. Unscrew the end cap counterclockwise and remove the end cap and secondary piston assembly from the master cylinder.
9. Remove the snap ring from the secondary piston and remove the piston and return spring from the end cap and stop rod assembly.
10. Remove the two lip seals from the piston.
11. Remove the snap ring from the end cap and remove the secondary piston stop rod, relief port seal spring, the two snap rings and the two split washers from the end cap.
12. Remove the relief port seal from the secondary piston stop rod.
13. Remove the O-rings from the end cap.
14. Remove the primary and secondary port caps and discard.
15. Remove the check valves and spring from the ports.

Assembly

Refer to Figure 15.

1. Wash all metal parts in alcohol before assembly. Dip all parts except the master cylinder body in clean C6AZ-19542-A **extra heavy duty hydraulic brake fluid. When using a master cylinder repair kit, install all of the parts supplied.**
2. Install a new primary piston into the front end of the master cylinder bore. Push the piston through the bore until it is flush with the retainer bushing recess. Use a non-metallic object which will not scratch the bore.
3. Assemble the O-rings and the two lip seals on the retainer bushing. Be sure the lip seals fit into the undercuts in the center of the bushing with their large diameters toward the piston end.
4. Install the retainer bushing onto the closed end of the push rod and push it onto the push rod approximately half way. Be sure the lip seal at the piston end of the retainer bushing remains in the undercut portion of the retainer bushing.
5. Install the seal retainer onto the closed end of the push rod with the raised lip toward the retainer bushing.
6. Insert the push rod into the master cylinder bore and hook the push rod onto the primary piston.
7. Slide the seal retainer into the recess in the master cylinder bore.
8. Screw the retainer bushing into the master cylinder body and tighten to 15-20 ft-lbs torque.
9. Install the push rod spring with the large end toward the master cylinder and install the spring retainer and snap ring.
10. Install the O-rings on the end cap.
11. Install the relief port seal on the secondary piston stop rod.
12. Place the port seal spring, split washer (largest of two), and snap ring (largest of two) on the piston stop rod.
13. Slide the assembly into the end cap and engage the snap ring into its groove.
14. Install the lip seals on the secondary piston with the large diameters facing outward.
15. Place the secondary piston return spring on the end cap assembly.
16. Compress the spring and place the remaining snap ring and split washer on the piston stop rod.
17. Slide the piston stop rod into the secondary piston and engage the snap ring in its groove.
18. Slide the end cap and piston assembly into the master cylinder bore and screw the end cap into the master cylinder body. Tighten the cap to 15-20 ft-lbs torque.
19. Install washers on the reservoir retainers and place the retainers in the mounting holes of the reservoir.
20. Place the rubber washers and O-rings on the retainers.
21. Place the reservoir and retainer

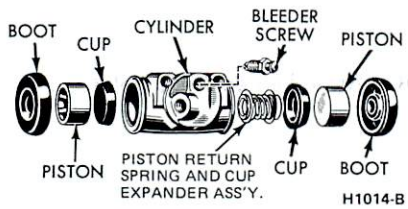

FIG. 12 Double Servo Brake Cylinder

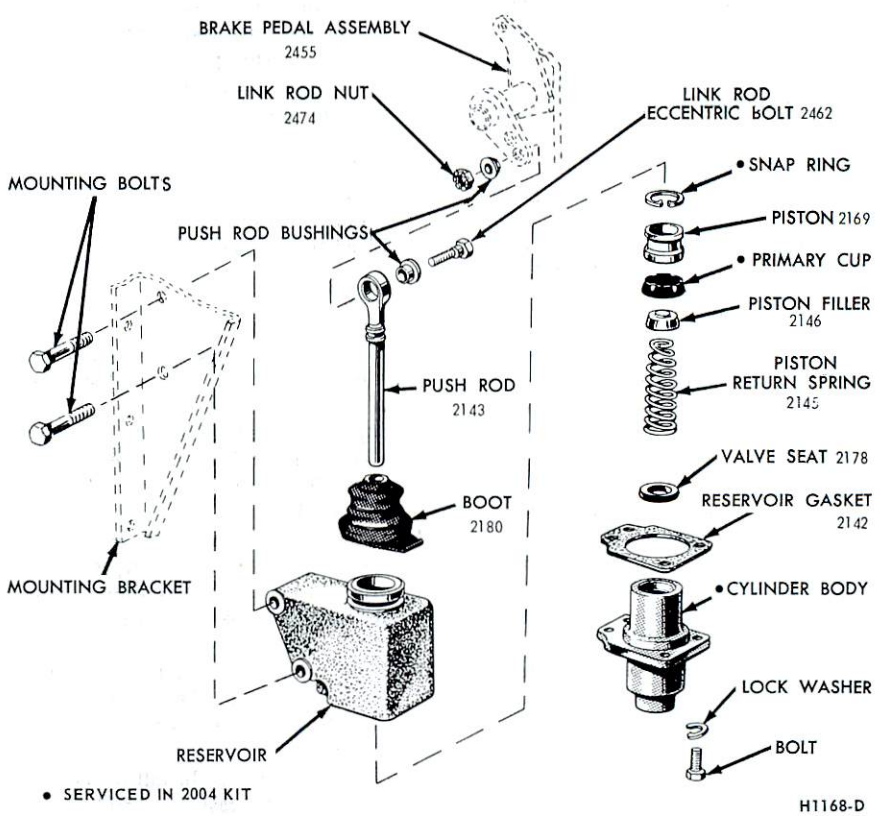

FIG. 13 C-Series Brake Master Cylinder—Disassembled

assembly on the master cylinder body and tighten the retainers to 15-20 ft-lbs torque.

22. Replace the springs and check valves in the output ports of the cylinder.
23. Replace the primary and secondary port caps. Tighten to 15-20 ft-lbs torque.
24. Install the mounting seal on the flange of the master cylinder. Install the filler cap and gasket (diaphragm).

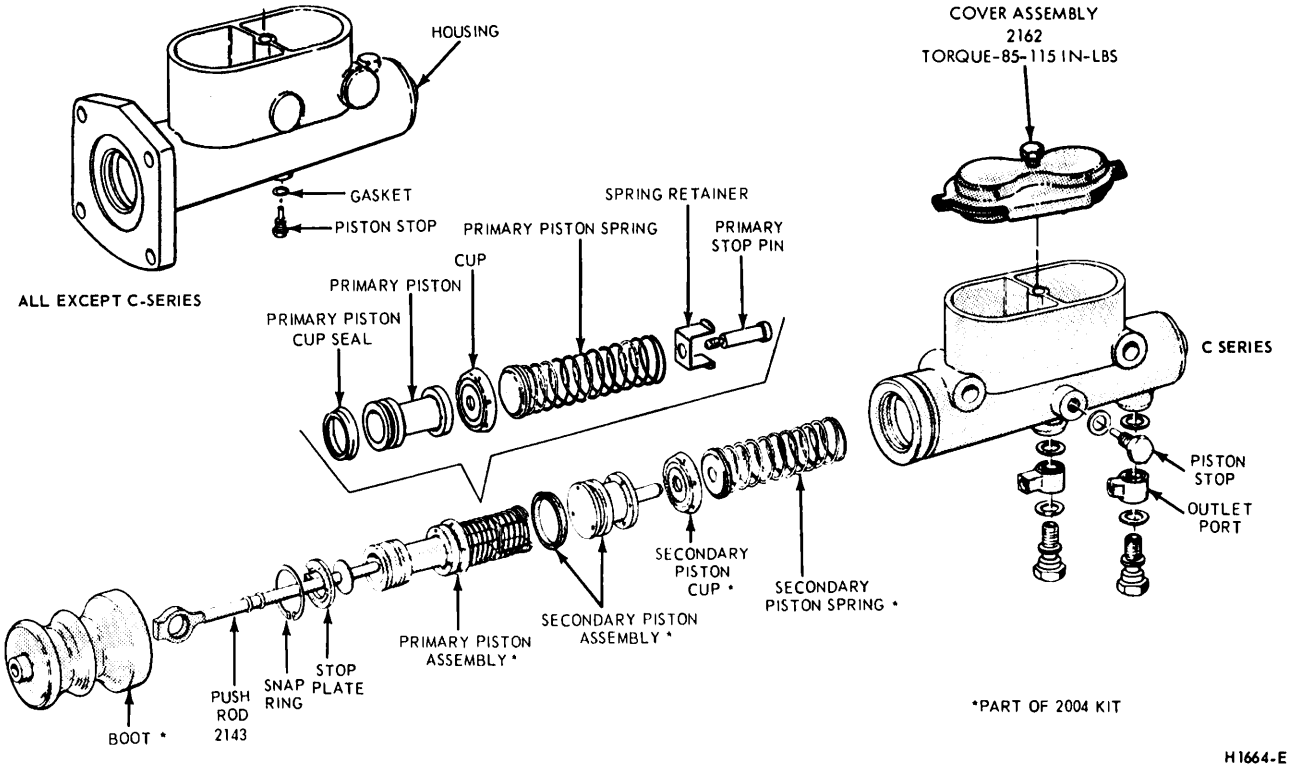

FIG. 14 Dual Master Cylinder—Disassembled View— 500-850-Series Trucks with Split Hydraulic Brakes and Frame-Mounted Booster

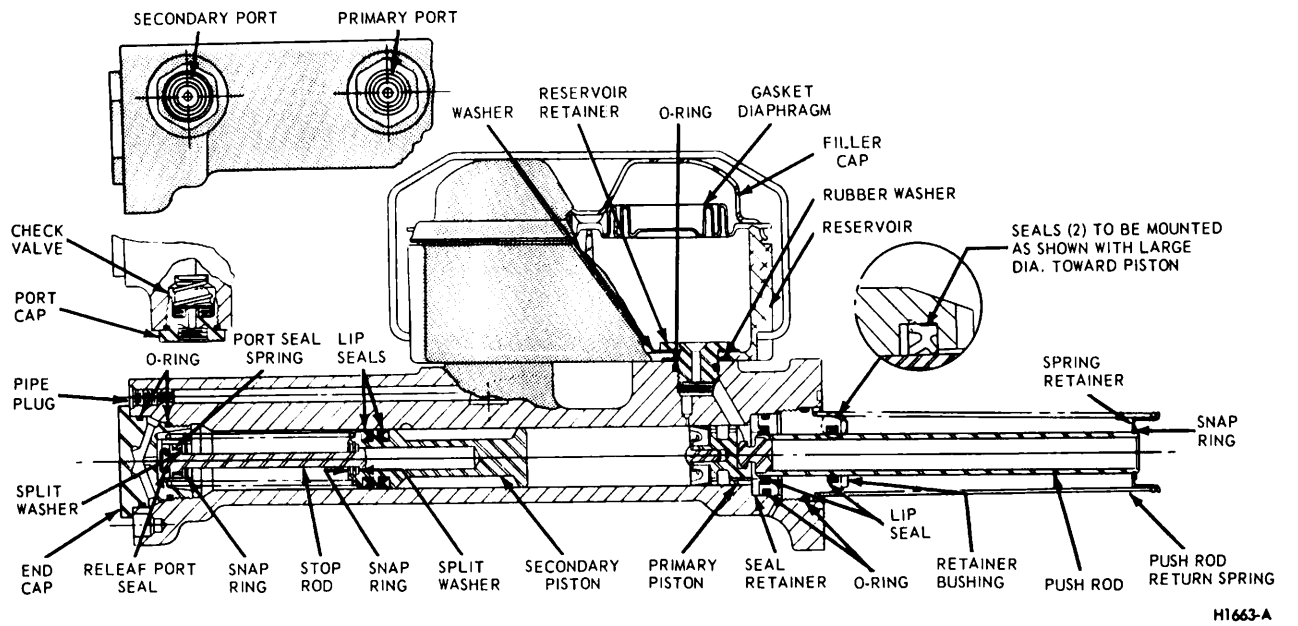

FIG. 15 Dual Master Cylinder—L-500-600, LN-6000, B-500-700 with Midland Ross Dash-Mounted Booster

SPECIFICATIONS

SPECIFIC TORQUE LIMITS

Front Brake Backing Plate to Spindle (100–400 Series)	1/2 x 13, 55-70	7/16 x 14, 30–50	1/2 x 20, 55–75
Front Brake Backing Plate and Steering Arm to Spindle (100–400 Series)	1/2 x 13, 30–40	1/2 x 20, 50–70	
Rear Backing Plate to Axle (100–400 Series)	1/2 x 13, 75–105	1/2 x 20, 50–70	7/16 x 14, 35–45
Brake Assembly to Front Axle (500–900 Series)	9/16 x 12, 110–150	1/2 x 13, 75–105	1/2 x 20, 75–105
Brake Assembly to Rear Axle (500–900 Series)	9/16 x 12, 110–150	1/2 x 13, 75–105	1/2 x 20, 75–105
Brake Drum to Hub Nuts or Bolts (500–900 Series)	1/2 x 13, 68–85	5/8 x 18, 136–170	
Master Cylinder or Booster Push Rod to Brake Pedal (500–900 Series)	3/8 x 16, 12–17		
Master Cylinder to Dash Panel (500–900 Series)	5/16 x 18, 12–17	3/8 x 16, 31–42	
Master Cylinder to Booster (Dash Mounted Booster) (500–700 Series)	14–18		
Booster to Dash Panel (Dash Mounted Booster) (500–700 Series)	3/8 x 16, 12–17	3/8 x 24, 13–20	5/16 x 18, 12–15
Master Cylinder to Pedal Bracket	5/16 x 24, 12–15	3/8 x 24, 12–17	
Eccentric Adjuster Bolt Torque	80–120 inch lbs.		

TORQUE LIMITS – HYDRAULIC TUBE NUTS (FT-LBS)

Thread Size	Ft-Lbs. ①	Thread Size	Ft-Lbs. ①
3/8–24	8–15	1/2–20	12–17
7/16–24	12–17	9/16–18	15–25

① All hydraulic line connections (nuts) must be torqued to the specified value and free of fluid leakage.

BRAKE DRUM REPAIR LIMITS (BRAKE LATHE)

Brake drums are marked with the maximum allowable braking surface diameter. If this diameter is exceeded by wear or refinishing, the drum must be replaced.

CH 1878-A

PART 12-09 Drum Brakes — Dual Cylinders, Single Piston (Wagner)

Applies To 600 Thru 900 Series Trucks

ADJUSTMENTS

BRAKE SHOE ADJUSTMENT

The brake drums should be at normal room temperature, when the brake shoes are adjusted. If the shoes are adjusted when the shoes are hot and expanded, the shoes may drag as the drums cool and contract.

A brake adjustment re-establishes the brake lining-to-drum clearance and compensates for normal lining wear.

Adjustment procedures for each type of brake assembly are given under the applicable heading.

SELF ADJUSTING BRAKES — 500-900 SERIES

Two-cylinder front brakes are adjusted by means of exposed, hex-head, self-locking cam adjusters. The brakes are to be manually adjusted initially. Subsequent adjustment is automatic. To adjust this brake:

1. Raise the vehicle and check the front brakes for drag by rotating the wheels.
2. Adjust one shoe by rotating the wheel in a forward direction while turning the cam hex-head also in a forward direction. Bring the shoe out to the drum until a light drag is felt. **Do not apply excessive force on the hex-head cam, as automatic adjuster parts can be damaged. Back off the adjustment until the wheel turns freely. Adjust the other cam on the same wheel in the same manner.**
3. Adjust the other front wheel brake using the procedure above.
4. Apply the brakes and recheck the adjustment.

REMOVAL AND INSTALLATION

BRAKE DRUMS THROUGH 900 SERIES

Removal and Installation

The brake drum service procedures for these models are covered under Removal and Installation in Part 12-01.

BRAKE SHOES AND ADJUSTING MECHANISM

600-900 SERIES

Removal

1. Raise the vehicle until the wheels clear the floor. Remove the wheel, and then remove the drum or the hub and drum assembly. **Mark the hub and drum to aid assembly in the same position.**

Be sure the engine is stopped and there is no vacuum in the system before disconnecting the hydraulic lines.

2. Remove both brake shoe retracting springs (Fig. 1).
3. Remove the C-washers and flat washers from the hold-down studs. Lift the shoes off the backing plate.
4. To remove the adjuster assembly from the shoe, unhook the wedge spring from the wedge and the coil spring from the shoe web. Work the spring coil off the lever pivot pin and slide the spring hook from the plug lever pin. Pull the adjuster lever from the back of the shoe and remove the plug, wedge washer, wedge and wedge guide.

Installation

1. To install the adjuster assembly, position the wedge guide with its pin located in the hole provided in the brake shoe. The wedge guide must be located on the side of the brake shoe farthest away from the carrier plate. Position the wedge on the shoe web with its serrated edge resting against the serrations on the wedge guide.
2. Insert the drum contact plug so that its head is through the hole in the brake shoe and lining and its shank rests over the wedge and wedge guide. The plug must be installed from the inside of the brake shoe.
3. From the opposite side of the shoe,

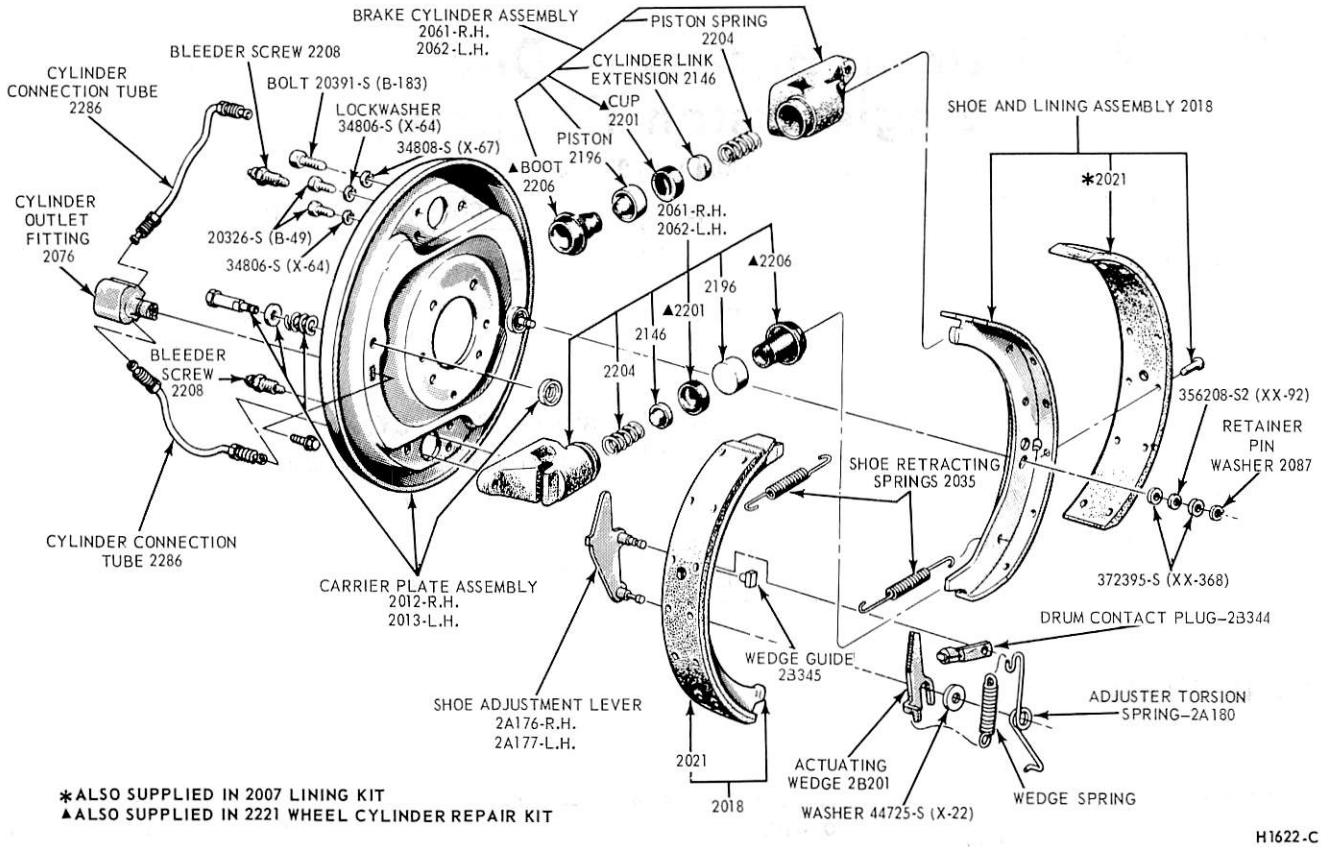

FIG. 1 Two-Cylinder Brake Shoe (Wagner) Front — Disassembled View

install the shoe adjustment lever, guiding the pin into the mating hole of the contact plug. Install the washer over the wedge on the lever pivot pin.

4. Position the U-hook of the adjuster torsion spring on the plug lever pin. Attach one end of the wedge spring to the hook, then install the coiled portion of the torsion spring over the lever pivot pin. Install the outer end of the torsion spring over the edge of the shoe web.
5. Connect the other end of the wedge spring to the hook of the wedge.
6. Fully retract the wedge against the lever pivot pin by pulling the wedge hook back while pressing on the contact plug head. If the plug protrudes above the lining, clamp the brake shoe in a vise so that its jaws clamp only the brake shoe web, while at the same time preventing the movement of the adjustment lever by resting it against the top of the vise jaw and file down the contact plug head. **Be careful not to file a flat spot on the lining. If the plug, when the mechanism is fully retracted, is greater than .006 inch below the lining surface, replace the plug and file it flush with the lining as described above.**
7. Place shoe assemblies on the carrier plate with the shoe hold-down studs through the oval shaped hole in the shoe webs. Locate the shoe assemblies to the wheel cylinders (Fig. 1).
8. Install the flat washers and bowed washers and crimp the C-washers on the hold-down studs to secure the shoes.
9. Install the brake shoe retracting springs so that the long end is hooked at the anchor end of the shoe. **Check that the shoe webs are engaged in the wheel cylinder piston insert slots.**
10. Install the hub and drum assembly.
11. Adjust the brakes as described in this part.

BRAKE WHEEL CYLINDER

Removal

1. Remove the wheel, drum, and brake shoes. Remove the cylinder-to-shoe connecting links.
2. Disconnect the brake line from the brake cylinder.
3. Remove the brake cylinder retaining bolts and lockwashers, and then remove the cylinder from the backing plate.

Installation

1. Position the brake cylinder on the backing plate and install the retaining bolts and lockwashers. Torque the small bolt to 150-200 in-lbs. Torque the larger bolt to 350-400 in-lbs as shown in Figure 1.
2. Install a new gasket on the brake line fitting and connect the line to the brake cylinder(s).
3. Install the brake shoes being sure that shoe webs engage slots in wheel cylinder piston insert. Install the drum and the wheel.
4. Adjust the brakes and bleed the system. Check the pedal operation before moving the vehicle.

BRAKE BACKING PLATE

500 THROUGH 900 SERIES

Removal

1. From front wheel spindles, remove the hub and drum attaching parts (axles under 9,000 lbs capacity grease cap and gasket if so equipped, cotter pin, bearing adjusting nut and flat washer. Axles 9,000 lbs capacity or over grease cap and gasket, lock nut, dimpled washer, locking ring, and bearing adjusting nut and pin

assembly). Then, remove the outer wheel bearing and the hub and drum assembly from the spindle.
2. On rear wheels, remove the rear axle shaft flange retaining nuts and axle shaft. Remove the rear wheel bearing lock nut, lock washer, and adjusting nut, then remove the hub and drum assembly from the axle housing. Discard the grease seal.
3. Remove the brake shoes and adjusting screw from the backing plate as outlined in this Section. Disconnect the brake line from the brake cylinder and submerge the end of the brake line in a can containing a small amount of brake fluid. This will minimize hydraulic line bleeding.
4. Remove the backing plate retaining bolts and nuts, then remove the backing plate from the front wheel spindle or rear axle housing.
5. Remove the attaching bolts and lock washers, and the brake cylinders from the backing plate.

Installation
1. Assemble the brake cylinders to the backing plate with the attaching bolts and lock washers.
2. Mount the backing plate to the front wheel spindle or to the rear axle housing flange, and secure with the attaching bolts and nuts.
3. Install the brake shoes and adjusting screw to the backing plate as outlined in this section. Connect the brake line to the brake cylinder.
4. Install a front wheel hub and drum assembly and the outer wheel bearing to the spindle. Install the hub and drum attaching parts (axles under 9,000 lbs capacity flat washer, bearing adjusting nut, cotter pin, grease cap, and gasket if so equipped, axles 9,000 lbs capacity or over — bearing adjusting nut and pin assembly, locking ring, dimpled washer, lock nut, and grease cap and gasket). Adjust the front wheel bearings as outlined in Group 11.

Install a rear wheel hub and drum assembly on the rear axle housing. **The rear hub oil seal must be replaced whenever a hub is removed or installed. Install the outer bearing and the adjusting nut, then adjust the wheel bearings. Install the lock washer and lock nut, then torque to specifications. Install the rear axle shaft, gasket and attaching nuts, then torque to specifications.**
5. Install the wheel and tire.
6. Bleed the hydraulic system and adjust the brake shoes.

BRAKE MASTER CYLINDER

L-, LN-, AND B-SERIES SPLIT BRAKE SYSTEM AND FRAME-MOUNTED BOOSTER

Removal

Refer to Figures 2 and 3.
1. Working from inside the vehicle below the instrument panel, disconnect the wires from the stop light switch.
2. On L-and LN-Series, remove the retaining nut, shoulder bolt, spacers and bushing securing the master cylinder push rod and the stop light switch to the brake pedal assembly. Remove the switch.

On B-Series, remove the hair pin clip from the brake pedal pin. Remove the push rod, spacers, stop light switch, and bushing from the brake pedal pin.
3. Remove the boot from the master cylinder push rod.
4. Disconnect the brake hydraulic system lines from the master cylinder.
5. Remove the master cylinder to dash panel retaining screws and remove the master cylinder.

Installation
1. Position the master cylinder assembly on the dash panel within the engine compartment and install the retaining screws and washers. Tighten the screws to specification.
2. Connect the hydraulic brake system lines loosely to the master cylinder.
3. Lubricate the push rod bushing with lubricant (Lubriplate). Position the bushing in the push rod.
4. On L-and LN-Series, position the stop light switch on the push rod, install the shoulder bolt and spacers. **Make sure the bushings and spacers are installed properly.** Secure the push rod and stop light switch to the brake pedal assembly with the selflocking nut.

On B-Series, install the spacers, push-rod, bushing and stop light switch on the brake pedal pin. Install the hair pin retainer.
5. Connect the wires to the stop light switch.
6. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this Section of the manual. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with C6AZ-19542-A extra heavy duty brake fluid. Install the gasket (diaphragm) and filler cap.

C-SERIES—SPLIT BRAKE SYSTEM

Removal

Refer to Figure 4.

All vacuum must be relieved from the booster before hydraulic lines are disconnected.
1. Disconnect the hydraulic lines from the master cylinder. Trap the fluid drip with a shop towel or plug the ports.
2. Remove the bolt and nut connecting the push rod to the brake pedal bell crank and remove the stop light switch, bushing and spacers.
3. Remove the master cylinder mounting bolts and remove the master cylinder from the vehicle.

Installation

Refer to Figure 4.
1. If the master cylinder is being replaced, transfer the outlet ports to the new master cylinder.
2. Position the master cylinder to the dash panel and install the mounting bolts.
3. Assemble the stop light switch, bushing and spacers on the push rod and install the bolt connecting the push rod to the bell crank.
4. Connect the primary and secondary outlet tubes and tighten to specifications.
5. Bleed the brake system.

L-500-900, LN-, AND LT-SERIES

Removal
1. Remove the brake pedal retracting spring (Fig. 2).
2. Remove the brake master cylinder push rod eccentric bolt nut, and remove the bolt and two nylon bushings.
3. Remove the nut from the pedal shaft. Then slide the shaft to the left and remove the brake pedal and sleeve.
4. Remove the two bushings from the pedal, and remove the bumper from the pedal extension bracket if so equipped.

Installation
1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Install the bumper on the pedal extension bracket (if so equipped), and position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly and sleeve in the pedal support bracket. Slide the pedal shaft through the sleeve and pedal and secure with the nut. Torque the nut to specifications.
4. Position the nylon bushings in the bore of the push rod. Connect the

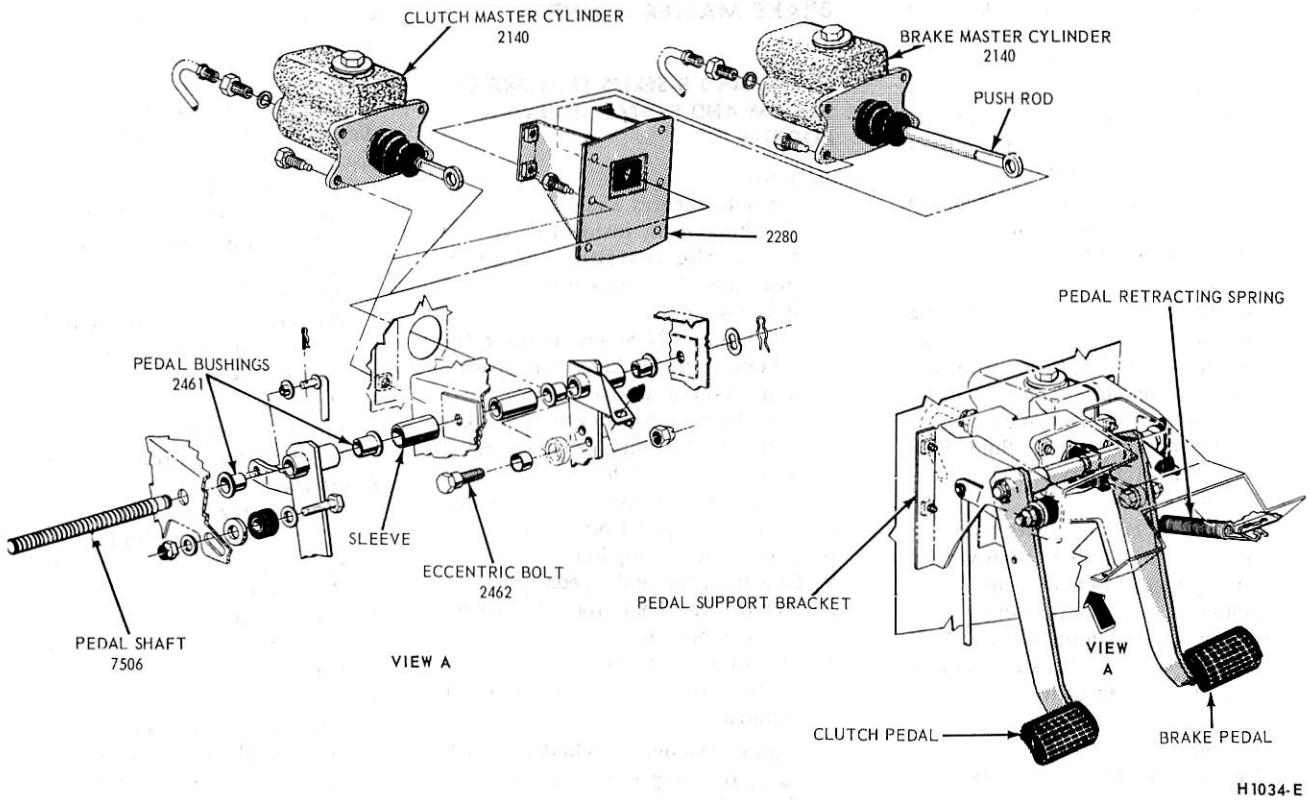

FIG. 2 L-, LN-, or LT-Series Brake Pedal and Related Parts

push rod to the brake pedal with the eccentric bolt and nut. Install the pedal retracting spring.
5. Torque the eccentric bolt nut to specifications.

B-SERIES

Removal

1. Remove the brake pedal retracting spring (Fig. 3).
2. Remove the clevis pin retaining clip and remove the pin, spacers, master cylinder push rod bushing and switch assembly.
3. Remove the clip from the pedal shaft. Then slide the shaft to the left and remove the brake pedal.
4. Remove the two bushings from the pedal.

Installation

1. Coat all bushings and the pedal shaft with a small quantity of Lubriplate or an equivalent lubricant.
2. Position the nylon bushings in the brake pedal shaft bore.
3. Position the brake pedal assembly in the pedal support bracket. Slide the pedal shaft through the pedal and secure with the retaining clip.
4. Position the nylon bushing in the bore of the push rod. Connect the push rod, switch assembly and

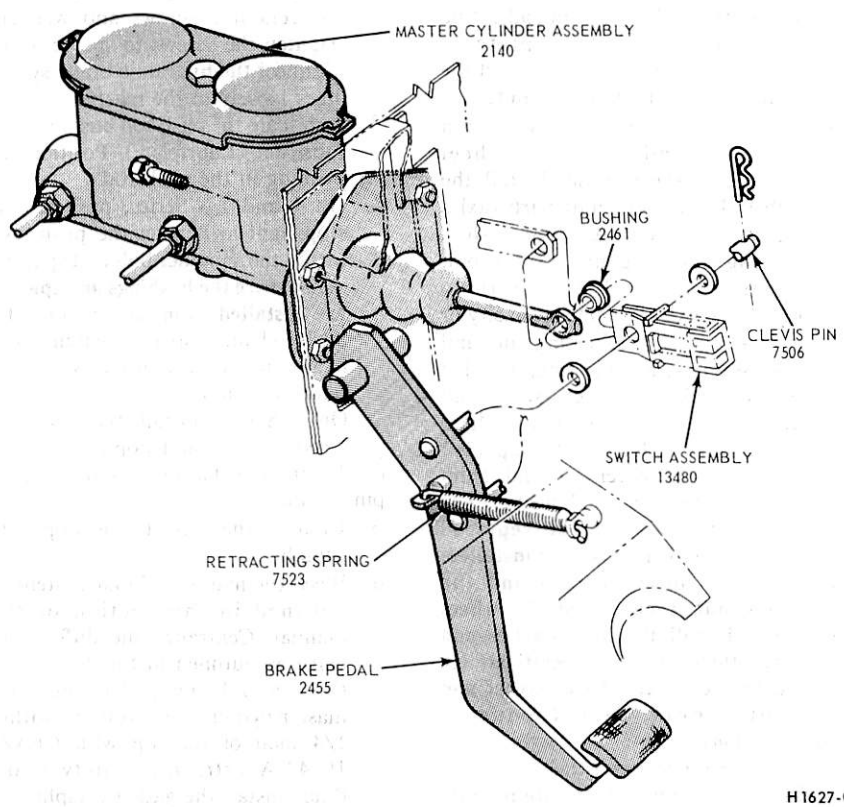

FIG. 3 B-Series Brake Pedal and Related Parts

spacers to the brake pedal with the clevis pin and secure with the retaining clip.
5. Install the pedal retracting spring.

C-SERIES

Removal

1. Remove the brake pedal retracting spring (Figs. 4 and 5).
2. Remove the brake master cylinder push rod eccentric bolt nut, bolt and nylon bushings.
3. Remove the brake pedal bumper-to-bracket retaining nut. Then remove the bolt and bumper.
4. On models with a single hydraulic brake system, remove the master cylinder push rod by pulling up on the tab on the push rod boot, and remove the push rod and boot from the cylinder.
5. Remove the nut from the bolt, slide the bolt to the right and remove the brake pedal assembly, sleeve and bushing.
6. Remove the bushings from the pedal assembly.

Installation

1. Coat all bushings and the pedal shaft, with a small quantity of Lubriplate or an equivalent lubricant. Position the nylon bushings in the brake pedal shaft bore.
2. Position the brake pedal assembly sleeve and bushing in the pedal support bracket, slide the bolt to the left and install the nut. Torque the nut to specifications.

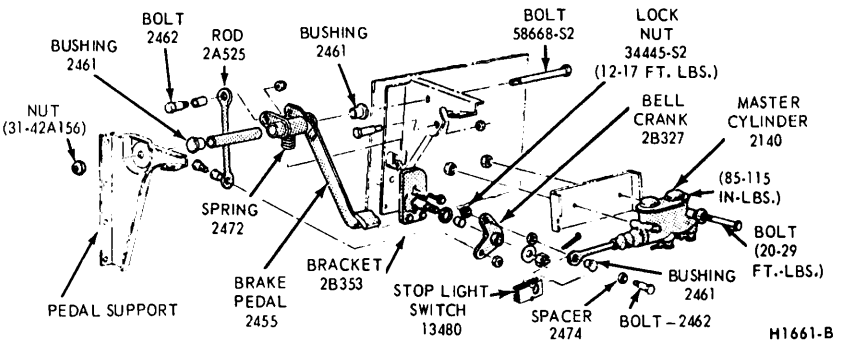

FIG. 4 Dual Master Cylinder and Brake Pedal Installation — C-Series

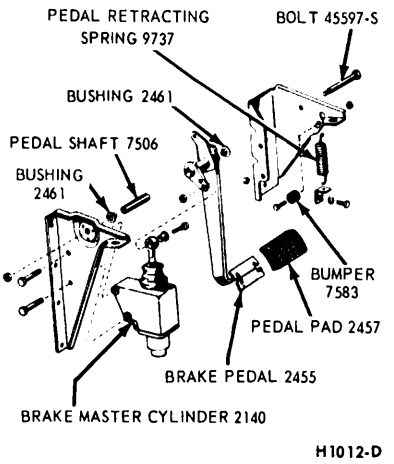

FIG. 5 Single Master Cylinder and Brake Pedal Installation — C- Series

3. On models with a single hydraulic brake system, install the push rod and boot in the master cylinder.
4. On models with a single hydraulic brake system, install the pedal bumper bolt, bumper and nut. Tighten the nut securely.
5. Install the two nylon bushings in the push rod bore, and install the push rod eccentric bolt and nut.
6. Install the pedal retracting spring.
7. On models with a single hydraulic brake system, adjust the brake pedal free-travel to 3/16-3/8 inch. Torque the eccentric bolt nut to specifications.

OVERHAUL

BRAKE WHEEL CYLINDER

Disassembly

Refer to Figure 6. With the wheel cylinder removed, remove the rubber boot from the end of the brake cylinder. Remove the piston, cup, and piston return spring from the cylinder (Fig. 6).

Assembly

1. Coat all brake cylinder parts with clean extra heavy duty brake fluid C6AZ-19542-A.
2. Install the bleeder screw (Fig. 6) in the brake cylinder.
3. Place the piston return spring, cup, and piston in the cylinder bore, and install a boot and link over each end of the cylinder, clamp the brake cylinder pistons against the end of the cylinder. **When a brake cylinder repair kit is used, install all of the parts supplied in the kit.**

MASTER CYLINDER

500-900 SERIES—SPLIT HYDRAULIC BRAKES AND FRAMEMOUNTED BOOSTER

Disassembly

Refer to Figure 7.

1. Clean the outside of the master cylinder. Remove the cylinder cover screw. Lift off the cover and the diaphragm gasket.
2. Loosen and remove the piston stop screw and gasket from the right hand side of the cylinder.
3. Pull back the push rod boot and remove the snap ring from the groove in the end of the cylinder bore.
4. Remove the push rod and stop plate from the master cylinder.

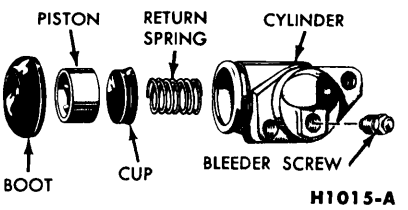

FIG. 6 Single Servo Brake Cylinder—Disassembled

5. Remove the internal parts from the master cylinder. If the parts will not slide out loosely assemble the cover plate and seal the primary outlet part, then apply air pressure at the secondary outlet port.

Inspection and Repair

1. Clean all parts in isopropyl alcohol. Inspect the parts for chipping, excessive wear or damage. Replace them as required. **When using a master cylinder repair kit, install all the parts supplied.**
2. Check all recesses, openings and internal passages to be sure they are open and free of foreign matter. Passages may be probed with soft copper wire, 0.020 inch OD, or smaller.
3. Minor scratches or blemishes in the cylinder bore can be removed with crocus cloth or a clean up hone. Do not oversize the bore more then 0.007 inch.

Assembly

Refer to Figure 7.

1. Dip all parts except the master cylinder in clean extra heavy duty C6AZ-19542-A hydraulic brake fluid.
2. Install the rear rubber cup on the secondary piston with the cup lip facing the rear. All other cups face the front or closed end of the cylinder.
3. Assemble and install the secondary piston spring, front cup, and the secondary piston.
4. Install the piston stop screw and gasket, making sure the screw enters the cylinder behind the rear of the secondary piston.
5. Assemble and install the primary piston and push rod parts.
6. Locate the stop plate in the seat in the bore and engage the snap ring into the groove at the rear of the cylinder.
7. Install the push rod boot onto the push rod and the groove of the cylinder housing.
8. Bleed the master cylinder.

Bleeding the Master Cylinder

Before the master cylinder is installed on the vehicle, the unit should be bled.

1. Support the master cylinder body in a vise, and fill both fluid reservoirs with C6AZ-19542-A extra heavy duty brake fluid.
2. Loosely install plugs in the front and rear brake outlet bores. Depress the primary piston several times until air bubbles cease to appear in the brake fluid.
3. Tighten the plugs and attempt to depress the piston. **The piston travel should be restricted after all air is expelled.**
4. Install the cover and diaphragm gasket assembly, and make sure the cover screw is tightened securely. Remove the plugs when the cylinder assembly is installed on the vehicle and is ready for hydraulic line connection.

L-AND LN-500-600 SERIES—SPLIT BRAKE SYSTEM AND DASH MOUNTED BOOSTER

Disassembly

Refer to Figure 8.

1. Clean the outside of the cylinder and remove the filler cap and gasket (diaphragm). Pour out any brake fluid that may remain in the reservoir. Stroke the push rod three times to remove fluid from the cylinder bore.
2. Remove the reservoir retainers, washers, and reservoir from the master cylinder body.
3. Remove the two rubber washers from the reservoir and the two O-rings from the reservoir retainers.
4. Remove the snap ring, spring retainer and push rod spring.
5. Unscrew the retainer bushing counterclockwise and remove the push rod, retainer bushing, seal retainer and primary piston from the master cylinder.
6. Remove the primary piston from the push rod and discard it.
7. Remove the seal retainer, and retainer bushing from the push rod. Remove the two lip seals and the two O-rings from the retainer bushing.
8. Unscrew the end cap counterclockwise and remove the end cap and secondary piston assembly from the master cylinder.
9. Remove the snap ring from the secondary piston and remove the piston and return spring from the end cap and stop rod assembly.
10. Remove the two lip seals from the piston.
11. Remove the snap ring from the end cap and remove the secondary piston stop rod, relief port seal spring, the two snap rings and the two split washers from the end cap.
12. Remove the relief port seal from the secondary piston stop rod.
13. Remove the O-rings from the end cap.
14. Remove the primary and secondary port caps and discard.
15. Remove the check valves and springs from the ports.

Assembly

Refer to Figure 8.

1. Wash all metal parts in alcohol before assembly. Dip all parts except the master cylinder body in clean C6AZ-19542-A **extra heavy duty hydraulic brake fluid. When using a master cylinder repair kit, install all of the parts supplied.**
2. Install a new primary piston into the front end of the master cylinder bore. Push the piston through the bore until it is flush with the retainer bushing recess. Use a non-metallic object which will not scratch the bore.
3. Assemble the O-rings and the two lip seals on the retainer bushing. Be sure the lip seals fit into the undercuts in the center of the bushing with their large diameters toward the piston end.
4. Install the retainer bushing onto the closed end of the push rod and push it onto the push rod approximately half way. Be sure the lip seal at the piston end of the retainer bushing remains in the undercut portion of the retainer bushing.
5. Install the seal retainer onto the closed end of the push rod with the raised lip toward the retainer bushing.
6. Insert the push rod into the master cylinder bore and hook the push rod onto the primary piston.
7. Slide the seal retainer into the recess in the master cylinder bore.
8. Screw the retainer bushing into the master cylinder body and tighten to 15-20 ft-lbs torque.
9. Install the push rod spring with the large end toward the master cylinder and install the spring retainer and snap ring.
10. Install the O-rings on the end cap.
11. Install the relief port seal on the secondary piston stop rod.
12. Place the port seal spring, split washer (largest of two), and snap ring (largest of two) on the piston stop rod.
13. Slide the assembly into the end cap and engage the snap ring into its groove.
14. Install the lip seals on the secondary piston with the large diameters facing outward.
15. Place the secondary piston return spring on the end cap assembly.
16. Compress the spring and place the remaining snap ring and split washer on the piston stop rod.
17. Slide the piston stop rod into the secondary piston and engage the snap ring in its groove.
18. Slide the end cap and piston

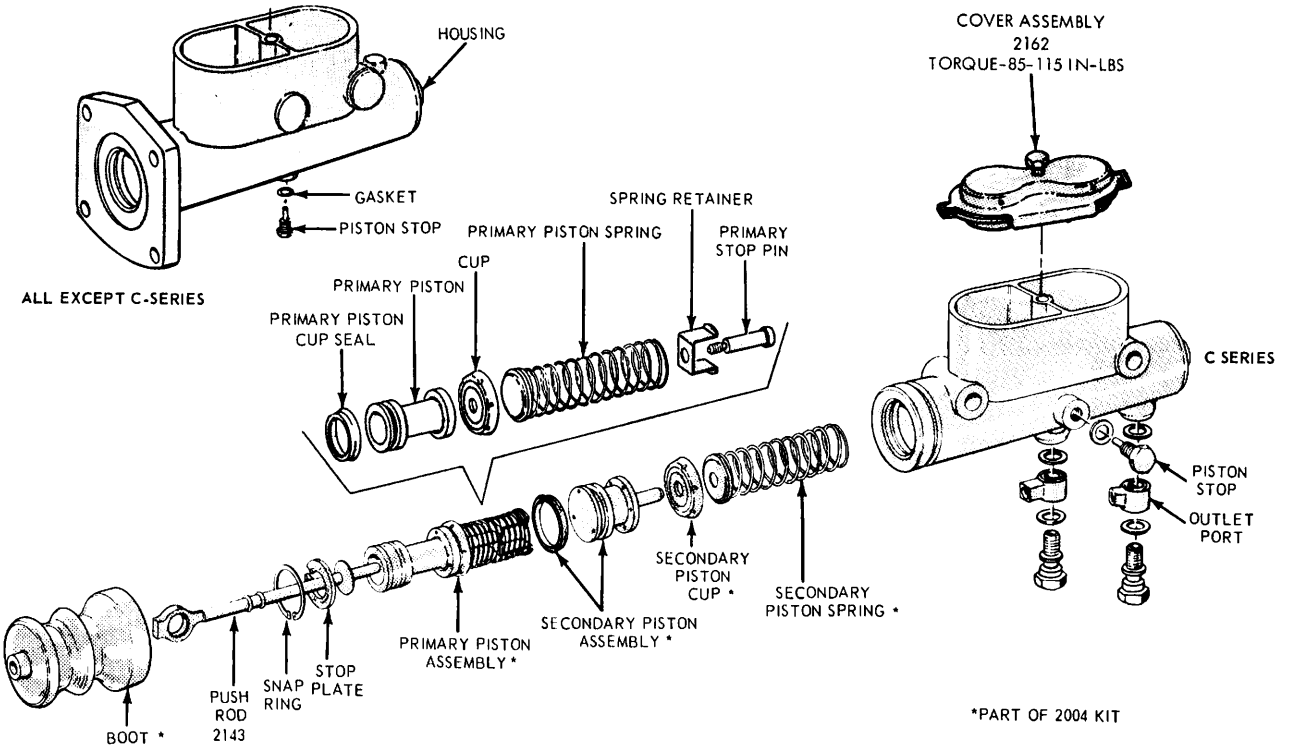

FIG. 7 Dual Master Cylinder—Disassembled View— 600-900 Series with Split Hydraulic Brakes and Frame-Mounted Booster

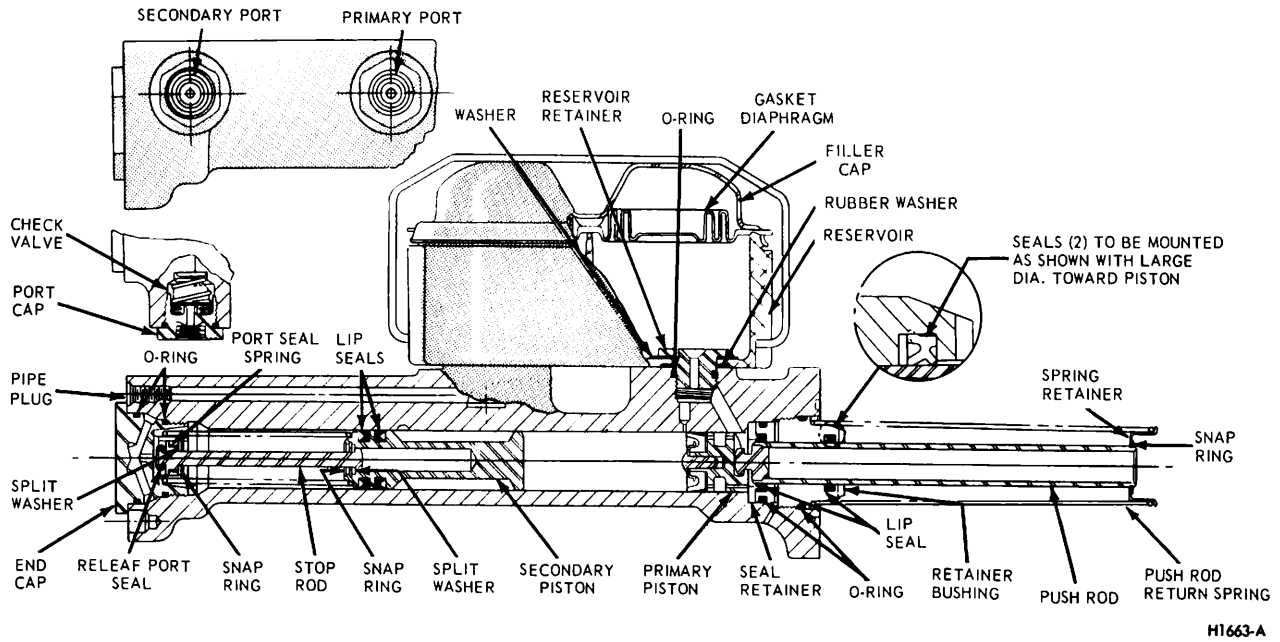

FIG. 8 Dual Master Cylinder — LN-600, LN-6000, B-500-700 with Midland Ross Dash-Mounted Booster

assembly into the master cylinder bore and screw the end cap into the master cylinder body. Tighten the cap to 15-20 ft-lbs torque.
19. Install washers on the reservoir retainers and place the retainers in the mounting holes of the reservoir.
20. Place the rubber washers and O-rings on the retainers.
21. Place the reservoir and retainer assembly on the master cylinder body and tighten the retainers to 15-20 ft-lbs torque.
22. Replace the springs and check valves in the output ports of the cylinder.
23. Replace the primary and secondary port caps. Tighten to 15-20 ft-lbs torque.
24. Install the mounting seal on the flange of the master cylinder. Install the filler cap and gasket (diaphragm).

SPECIFICATIONS

DESCRIPTION

FLOATING CALIPER DISC BRAKES

F-250 above 6200 G.V.W. and F-350 4 x 2 model trucks are equipped with dual piston, floating caliper disc brakes in the front (Figs. 1 and 2) and conventional drum brakes in the rear. The system has a dual master cylinder and vacuum booster.

The dual, master cylinder contains a double hydraulic cylinder with two fluid reservoirs and two hydraulic pistons (a primary and secondary). The master cylinder secondary systems outlet port is connected to the secondary (rear) hydraulic circuit and the primary system brake outlet port is connected to the primary (front) hydraulic circuit.

The master cylinder primary and secondary pistons function together when the primary and secondary systems are fully operative.

Brake lines (tubes) are connected from the brake master cylinder primary and secondary system outlet ports to the pressure differential valve assembly (Fig. 3). The electrical brake warning switch, and the brake lines (tubes) leading from the differential valve assembly to the rear wheel brake cylinders, the front brake metering valve and calipers are also shown in Fig. 3.

A metering valve is located on the No. 1 front crossmember in the front brake line between the pressure differential valve and the disc brake calipers.

The disc brake is the floating caliper design with two pistons on one side of the rotor. It is a two piece unit consisting of the caliper and cylinder housing. The caliper is mounted to the anchor (support) plate on two mounting pins and bushings in the anchor plate.

Two brake shoe and lining assemblies are used in each caliper, one on each side of the rotor. The shoes are identical and are attached to the caliper with two mounting pins and anti-rattle springs.

The cylinder housing contains the two pistons. The pistons and cylinder bores are protected by boot seals which are fitted to a groove in the piston and attached to the cylinder housing. The cylinder assembly is attached to the caliper with two cap screws and washers.

The anchor plate (support assembly) is bolted directly to the spindle. It positions the caliper assembly over the rotor forward of the spindle.

Refer to Figs. 1 and 2.

SLIDING CALIPERS DISC BRAKES

The disc brake assembly used on F-100 4 x 2 and E-250 4 x 2 (through 6200 GVW) trucks. (Figs. 4, 5 and 6) is a sliding caliper, single piston type and is different in the manner in which the caliper is attached to its supporting member. The supporting member and steering arm are cast as one piece and are combined with a wheel spindle stem to form an integral spindle assembly.

The inner shoe and lining assembly is installed with the ends of the shoe confined within the spindle assembly. An anti-rattle clip is positioned between the leading edge of the shoe and the spindle assembly at the bottom of the caliper. The outer shoe and lining is installed with the shoe flange bearing against the shoe locating and torque abutment surfaces on the caliper.

The linings are riveted to the shoes, and an insulating pad is attached to the back of each shoe. On the inner shoe, the insulating pad is between the end of the

piston and the shoe, while on the outer shoe, the insulating pad is between the outer legs of the caliper housing and the shoe. The inner and outer shoes are not interchangeable.

The caliper housing (Fig. 3) is a single piece finished casting which is positioned on the spindle assembly against machined surfaces at the trailing end. A caliper support key is installed between the leading edge of the caliper and the spindle assembly with a support spring inserted between the key and the caliper. A key retaining screw keeps the key from sliding out of the spindle assembly.

A single hydraulic piston is inserted into the cylinder bore in the caliper housing with the hydraulic fluid inlet coming into the top of the bore. A square section seal is fitted into an annular groove in the caliper cylinder bore, and a rubber boot is used to seal the piston and caliper bore from road splash and contamination. A bleeder screw is located above the cylinder bore to bleed air from the system.

A ventilated rotor is integrally cast with the wheel hub. A single piece splash shield, which is bolted to the spindle, protects the bearings and inboard surface of the rotor from road splash. The wheel protects the outboard surface of the rotor and brake assembly.

When the brake pedal is depressed, brake fluid from the master cylinder passes through the proportioning valve (Figs. 7 and 8) into the caliper cylinder. This moves the piston outward and forces the inner shoe and lining assembly against the inboard surface of the rotor.

The reaction of the inner lining pressing against the rotor moves the caliper housing slightly inboard. The outer legs of the caliper housing force the outer shoe and lining assembly against the outboard surface of the rotor.

The two shoe and lining assemblies clamp the rotor in a vise-type movement to provide the braking action. The braking torque is transferred from the linings to the shoes. The torque from the inner shoe is transferred directly to the spindle assembly, while the torque from the outer shoe is transferred through the caliper to the spindle assembly.

When the brake pedal is released, the piston seal retracts the piston into the cylinder, and the caliper housing slides slightly outboard, releasing the brakes.

The Combination Pressure differential proportioning and metering valve (Fig. 7) is attached to the Left frame siderail.

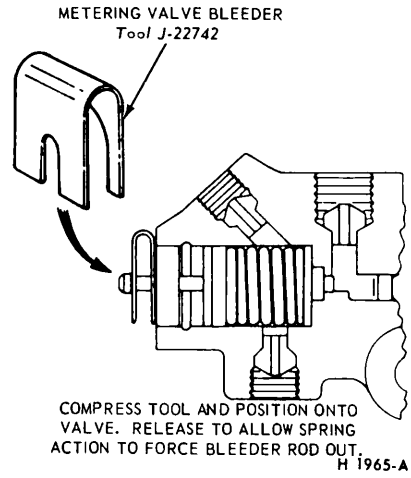

FIG. 8 Pressure Bleeding Tool—Sliding Caliper Disc Brakes

ADJUSTMENTS

DISC BRAKE SHOE ADJUSTMENT

The front disc brake assembly is designed so that it is inherently self-adjusting and requires no manual adjustment.

Automatic adjustment for lining wear is achieved by the piston sliding outward in the cylinder bore. The piston assumes a new position in the cylinder and maintains the correct adjustment.

HYDRAULIC SYSTEM BLEEDING

When any part of the hydraulic system has been disconnected for repair or replacement, air may get into the lines and cause spongy pedal action. This requires the bleeding of the hydraulic system after it has been properly connected to be sure all air is expelled from the brake cylinders and lines. The hydraulic system can be bled manually or with pressure bleeding equipment.

When bleeding the brake system, bleed one brake cylinder at a time, beginning at the cylinder with the longest hydraulic line first. Keep the master cylinder reservoir filled with the specified brake fluid during the bleeding operation. Never use brake fluid which has been drained from the hydraulic system.

It is necessary to depress the bleeder button on the metering valve (Fig. 9) when bleeding the front brakes on vehicles equipped with floating calipers. On vehicles equipped with sliding calipers, the metering rod of the proportioning valve must be pulled outward as shown in Fig. 8. This is to allow the brake fluid to reach the caliper assemblies. This operation is particularly important if pressure bleeding equipment is being used.

The pressure differential valves are self-centering after a brake hydraulic system malfunction has been corrected and the hydraulic system has been bled.

Manual Bleeding

The front and rear hydraulic brake systems are individual systems and are bled separately. Bleed the longest line first on the individual system being serviced. **During the complete bleeding operation, DO NOT allow the reservoir to run dry. Keep the master cylinder reservoirs filled with the specified brake fluid. Never use brake fluid that has been drained from the hydraulic system.**

1. Bleed the master cylinder at the outlet port side of the system being serviced.

On a master cylinder, loosen the master cylinder to hydraulic line nut. Operate the brake pedal slowly until the brake fluid at the outlet connection is free of bubbles, then tighten the tube nut to specified torque. **Do not use the secondary piston stop screw located on the bottom of the master cylinder to bleed the brake system. Loosening or removing this screw could result in damage to the secondary piston or stop screw.** Operate the brake pedal slowly until the brake fluid at the outlet connection is free of air bubbles, then tighten the bleed screw.

2. Position a suitable 3/8 inch box wrench on the bleeder fitting on the right rear brake wheel cylinder. Attach a rubber drain tube to the bleeder fitting. The end of the tube should fit snugly around the bleeder fitting.
3. Submerge the free end of the tube in a container partially filled with clean brake fluid, and loosen the bleeder fitting approximately 3/4 turn.
4. Push the brake pedal down slowly thru its full travel. Close the bleeder fitting, then return the pedal to the fully-released position. Repeat this operation until air bubbles cease to appear at the submerged end of the bleeder tube.

5. When the fluid is completely free of air bubbles, close the bleeder fitting and remove the bleeder tube.
6. Repeat this procedure at the brake wheel cylinder on the opposite side. Refill the master cylinder reservoir after each wheel cylinder is bled. On disc brakes, bleed the right front caliper first. When the bleeding operation is complete, the master cylinder fluid level should be filled to within 1/4 inch from the top of the reservoirs.
7. The pressure differential valves are self-centering. Refer to the Centralizing of the Pressure Differential Valve procedures in this Section.

Pressure Bleeding

Bleed the longest lines first. The bleeder tank should contain enough of the specified brake fluid to complete the bleeding operation. The tank should be charged with approximately 10 to 30 pounds of air pressure. Never exceed 50 pounds pressure. **Never use brake fluid that has been drained from the hydraulic system.**

1. Clean all dirt from the master cylinder reservoir cover.
2. Remove the master cylinder reservoir cover and rubber gasket, and fill the master cylinder reservoir with the specified brake fluid. Install the pressure bleeder adapter tool to the master cylinder, and attach the bleeder tank hose to the fitting on the adapter.

Master cylinder pressure bleeder adapter tools can be obtained from the various manufacturers of pressure bleeding equipment. Follow the instructions of the manufacturer when installing the adapter.

3. Position a suitable 3/8 inch box wrench on the bleeder fitting on the right rear brake wheel cylinder. Attach a bleeder tube to the bleeder fitting. **The end of the tube should fit snugly around the bleeder fitting.**
4. Open the valve on the bleeder tank to admit pressurized brake fluid to the master cylinder reservoir.

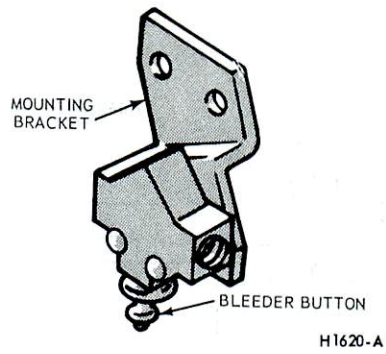

FIG. 9 Metering Valve

5. Submerge the free end of the tube in a container partially filled with clean brake fluid, and loosen the bleeder fitting.
6. When air bubbles cease to appear in the fluid at the submerged end of the bleeder tube, close the bleeder fitting and remove the tube.
7. Repeat steps 3 through 6 at the opposite wheel cylinder of the system being bled. On front brakes, bleed the right front caliper first.
8. When the bleeding operation is completed, close the bleeder tank valve and remove the tank hose from the adapter fitting.
9. Remove the Pressure Bleeder Adapter Tool. Fill the master cylinder reservoirs to within 1/4 inch from the top. Install the master cylinder cover and gasket.
10. Centralize the pressure differential valve.

CENTRALIZING THE PRESSURE DIFFERENTIAL VALVE

1. Turn the ignition switch to the ACC or ON position. Operate the brake pedal carefully and gradually until the pressure differential valve is returned to a centralized position and the brake warning light goes out.
2. Check the fluid level in the master cylinder reservoirs and fill them to within 1/4 inch of the top with the specified brake fluid.
3. Turn the ignition switch to the OFF position.

HYDRAULIC LINE REPAIR

Steel tubing is used in the hydraulic lines between the master cylinder and the front brake tube connector, and between the rear brake tube connector and the rear brake cylinders. Flexible hoses connect the brake tube to the front brake cylinders and to the rear brake tube connector.

When replacing hydraulic brake tubing, hoses, or connectors, tighten all connections securely. After replacement, bleed the brake system at the wheel cylinders and at the booster, if so equipped.

Brake Tube

If a section of the brake tube becomes damaged, the entire section should be replaced with tubing of the same type, size, shape, and length. **Copper tubing should not be used in the hydraulic system.** When bending brake tubing to fit the frame or rear axle contours, be careful not to kink or crack the tube.

All brake tubing should be double flared (refer to Part 12-01) to provide good leak-proof connections. Always clean the inside of a new brake tube with clean isopropyl alcohol.

Brake Hose

A flexible brake hose should be replaced if it shows signs of softening, cracking, or other damage.

When installing a new brake hose, position the hose to avoid contact with other truck parts. Also, whenever a brake hose is disconnected from a wheel cylinder or brake caliper a new copper washer must be used when re-connecting the hose.

REMOVAL AND INSTALLATION

BRAKE SHOES AND LINING

F-250—F-350 (ABOVE 6200 G.V.W)

Replace shoe and lining assemblies when lining is worn to a minimum of 1/16 inch in thickness (combined thickness of shoe and lining-1/4 inch minimum). **Always replace shoes and lining assemblies in axle sets—never one wheel only.**

Removal

1. Remove the wheel and tire assembly.
2. Remove the shoe and lining mounting pins, anti-rattle springs and old shoe and lining assemblies (Fig. 3).

Installation

1. Remove the master cylinder cover.
2. Loosen the piston housing-to-caliper mounting bolts sufficiently to permit the installation of new shoe and lining assemblies. **Do not move pistons.**
3. Install new shoe and lining assemblies. Install the brake shoe mounting pins and anti-rattle spring. **Be sure that the spring tangs are located in the holes provided in the shoe plates.**
4. Torque the brake shoe mounting pins to 17-23 ft-lbs.
5. Reset the pistons to the correct location in the cylinders by retightening the piston housing-to-caliper mounting bolts. **Keep the cylinder housing square with the caliper. Check the master cylinder for brake fluid overflow.**
6. Torque the piston housing-to-caliper mounting bolts to 155 to 185 ft.-lb.
7. Install the wheel and tire assembly.
8. Check the master cylinder reservoirs and (if required) fill with the specified brake fluid to within 1/4 inch from the top.
9. Install the master cylinder cover.

BRAKE SHOES AND LINING

F-100-F-250 (THROUGH 6200 G.V.W.)

Removal

Always replace shoe and lining assemblies in complete axle sets—never one wheel only.

1. Siphon or dip part of the brake fluid out of the larger master cylinder reservoir (the reservoir connected to the front disc brakes). When the caliper pistons are pressed back into the caliper cylinder bores and the brake fluid returns from the calipers, the reservoir may overflow if fluid is not removed. Discard the fluid removed.
2. Raise the vehicle and remove a front wheel and tire assembly.
3. Place a large (8 inch) C-clamp on the caliper as illustrated in Fig. 10, and tighten the clamp to bottom the caliper piston in the cylinder bore. Then remove the clamp.
4. Remove the key retaining screw (Fig. 11).
5. Use a brass rod and a light hammer to drive out the caliper support key and caliper support spring (Fig. 12). It is not necessary to disconnect the hydraulic line to the caliper; thus, it should not be necessary to bleed the brakes after the new shoes are installed.
6. Remove the caliper from the spindle assembly, by pushing the caliper downward against the spindle assembly, and rotating the upper end upward and out of the spindle assembly. Lay the caliper on a tie rod. **Do not let the caliper hang with the weight of the caliper on the brake hose. The brake hose must not be stretched or twisted.**
7. Remove the outer shoe and lining from the caliper (Fig. 13). It may be necessary to tap the shoe to loosen the shoe flange from the caliper.
8. Remove the inner shoe and lining from the spindle assembly (Fig. 14), and remove the shoe anti-rattle clip from the lower shoe abutment surface of the spindle assembly.
9. Clean and inspect the caliper assembly. **It is important to clean those areas of the caliper and spindle assembly that are in contact during the sliding action of the caliper.**

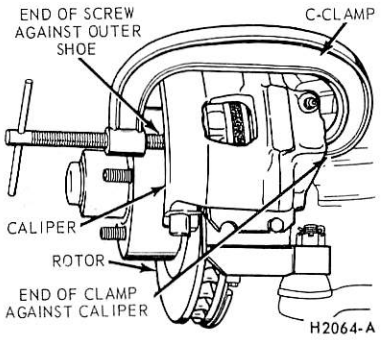

FIG. 10 Bottoming Caliper Piston

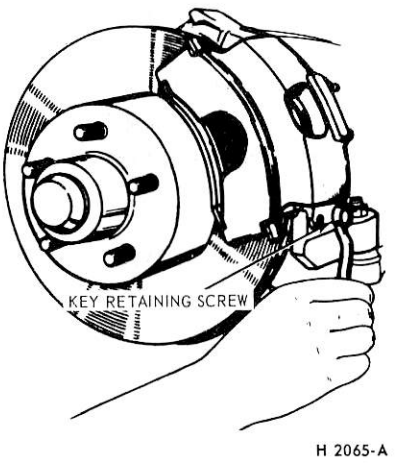

FIG. 11 Removing Key Retaining Screw

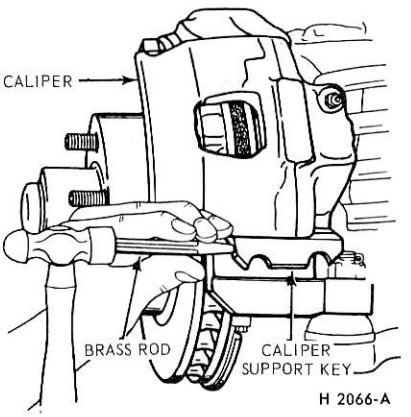

FIG. 12 Removing Caliper Support Spring and Key

Installation

1. Position a new anti-rattle clip in the lower shoe abutment in the spindle assembly (Fig. 15). Be sure that the tabs on the clip are positioned properly and the loop-type spring is positioned away from the rotor.
2. Place the lower end of the inner shoe and lining in the spindle assembly shoe abutment against the anti-rattle clip, and slide the upper end of the shoe into position. Be sure that the clip is still in position.
3. Be sure that the caliper piston is fully bottomed in the cylinder bore. If necessary, use a large C-clamp to assist.

The service replacement outer shoe and lining differs slightly from the outer

shoe and lining originally installed. The replacement shoe has tabs added to the flange on the lower edge of the shoe, and the distance between the upper tabs and lower flange is reduced to provide a slip-on interference fit.

4. Position the outer shoe and lining on the caliper, and use fingers to press the shoe tabs into place. If the shoe cannot be pressed into place by hand, a C-clamp may be used as shown in Fig. 15 to press the shoe into position. Be careful not to mar the lining with the clamp.
5. Position the caliper on the spindle assembly by pivoting caliper about the spindle upper mounting surface. Be very careful when installing the caliper to prevent tearing or cutting the boot as it slips over the inner shoe.
6. Use a brake adjusting tool or a screwdriver (Fig. 16) to hold the upper machined surface of the caliper against the surface of the spindle assembly. Then install a new caliper support spring and new caliper support key (Figs. 17 and 18). Use a soft (brass or plastic) mallet to drive the key and spring assembly into position (Fig. 18), and then install the key retaining screw. Tighten the screw to 12-18 ft-lbs.
7. After new shoes and linings and the wheel assemblies have been installed on both front wheels, lower the vehicle. Check the master cylinder reservoirs, and fill, if necessary with heavy duty (ESA-MC-625-A) brake fluid.

Press on the brake pedal firmly several times to seat the linings on the rotor. **Do not move the vehicle until a firm pedal is obtained.**

DISC BRAKE CALIPER

F-250—F-350 (ABOVE 6200 G.V.W.)

Removal

Refer to Figure 2.

1. Raise the front of the vehicle.
2. Remove the wheel cover.
3. Remove the wheel and tire assembly.
4. Remove the pins and nuts retaining the caliper assembly to the anchor plate.

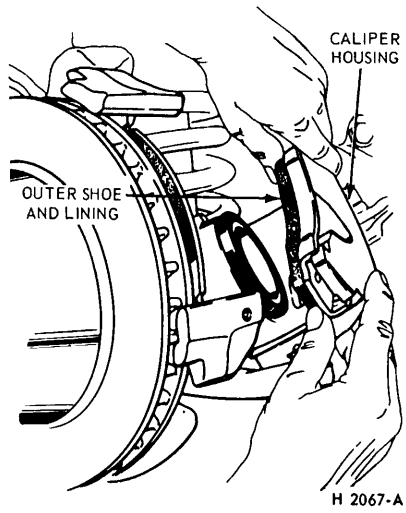

FIG. 13 Removing Outer Shoe and Lining

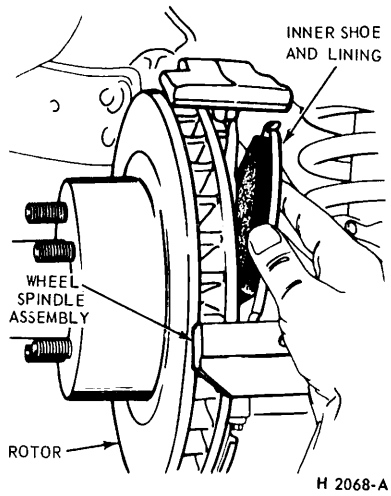

FIG. 14 Removing Inner Shoe and Lining

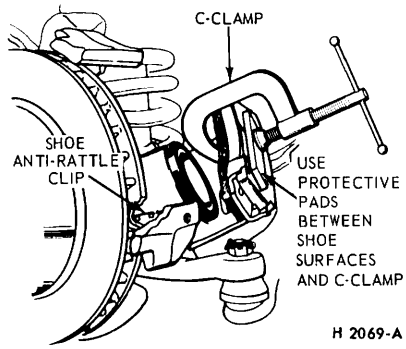

FIG. 15 Installing Anti-Rattle Clip and Outer Shoe and Lining

5. Disconnect the brake hose from the caliper and remove the caliper.

Installation

1. Connect the brake hose to the caliper. **Use a new copper washer.**
2. Position the caliper assembly to the anchor plate and install the retaining pins and nuts. **Coat the pins with a light film of chassis lube (C1AZ-19590-B) before installation.** Torque the nuts to specifications.
3. Install the wheel and tire assembly and install the wheel cover.
4. Bleed the brake system.
5. Lower the vehicle.

CALIPER MOUNTING PIN BUSHING

Removal

1. Pry the bushing assembly out of the support assembly boss by inserting a screwdriver blade or other suitable tool under the outer lip of the bushing assembly steel shell.

Installation

1. Press the bushing assembly into the support assembly mounting pin boss as shown in Fig. 19. A suitable tool for installing the bushing assembly consists of a caliper mounting pin fitted with a 1/2 inch washer as shown in Fig. 19.
2. The sealing ring of the bushing assembly rubber insert should make light contact with the bottom of the mounting pin boss counterbore.
3. Lubricate the interior of the mounting pin boss and the bushing assemblies with chassis lube (C1AZ-19590-B)

DISC BRAKE CALIPER

F-100—F-250(THROUGH 6200 G.V.W.)

1. Raise the vehicle and remove the tire and wheel.
2. Disconnect the brake hose from the caliper inlet port. Cap the hose and plug the inlet port to prevent fluid leakage.
3. Remove the caliper and the shoe and lining assemblies as outlined under Shoe and Lining Removal. Be careful to avoid getting grease or brake fluid on the linings.

Visually inspect the caliper housing for leakage. If leakage is evident, overhaul the caliper. A small amount of brake fluid wetness inside of the boot is normal.

4. Use a wire brush to remove any rust or corrosion from the machined surfaces of the spindle assembly and caliper. **It is important to clean those areas of the caliper and spindle assembly that are in contact during the sliding action of the caliper.**

Installation

1. Install the shoe and lining assemblies and the caliper as described under Shoe and Lining Installation.
2. Connect the hydraulic hose to the caliper inlet port. Use a new copper washer when connecting the hose.
3. Bleed the brake system.
4. Install the tire and wheel assemblies and lower the vehicle.

DISC BRAKE HUB AND ROTOR

Removal

Refer to Figure 2.

1. Raise the front of the vehicle and install stands.
2. Remove the wheel and tire assembly.
3. Remove the caliper assembly from the rotor and position it out of the way with wire. Refer to Caliper Removal.
4. Remove the dust cap, cotter pin, nut, washer and outer bearing and remove the rotor from the spindle.
5. Remove inner bearing cone and seal. Discard the seal.

Installation

1. If a new hub and rotor is being installed, remove the protective coating or any dirt or grease deposits with a suitable degreaser.
2. Pack the inner and outer bearing cone with bearing grease.
3. Install the inner bearing cone and seal. Refer to Group 11, Part 11-10.
4. Install the hub and rotor onto the spindle.
5. Install the outer bearing cone, washer and nut. Adjust the bearing and install the cotter key and dust cap. Refer to Group 11, Part 11-10.
6. Install the Caliper. Refer to Caliper Installation.
7. Install the wheel and tire assembly.
8. Lower the vehicle.

MASTER CYLINDER

Removal

Refer to Figure 20.

1. With the engine stopped, depress the brake pedal to expel all vacuum from the brake booster system.

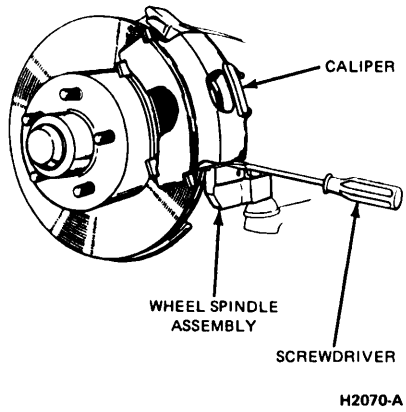

FIG. 16 Installing Caliper

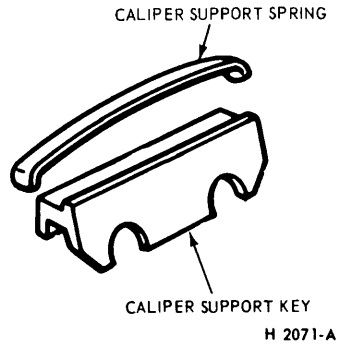

FIG. 17 Caliper Support Spring and Key

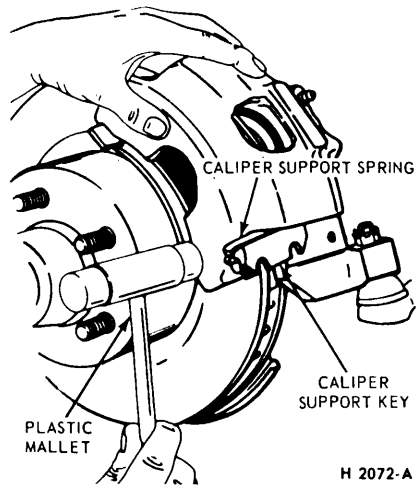

FIG. 18 Installing Caliper Support Spring and Key

2. Disconnect the hydraulic lines from the brake master cylinder.
3. Remove the brake booster to master cylinder retaining nuts and lockwashers. Remove the master cylinder from the brake booster.

Installation

1. Before installing the master cylinder, check the distance from the outer end of the booster assembly push rod to front face of the brake booster assembly. Turn the push rod adjusting screw in or out as required to obtain the specified length (Part 12-05).

Failure to maintain this dimension can prevent the master cylinder piston from completely releasing hydraulic pressure and can cause the brakes to drag.

To check the adjustment of the screw, fabricate a gauge of the dimensions shown in Part 12-05. Then, place the gauge against the master cylinder mounting surface of the booster body. The push rod screw should be adjusted so that the end of the screw just touches the inner edge of the slot in the gauge.

2. Position the master cylinder assembly over the booster push rod and onto the two studs on the booster assembly. Install the attaching nuts and lockwashers and torque them to specifications.
3. Connect the hydraulic brake system lines loosely to the master cylinder.
4. Bleed the hydraulic brake system as outlined in this section of the manual. Centralize the differential valve as outlined in this section of the manual if required. Then, fill the dual master cylinder reservoirs to within 1/4 inch of the top with the specified brake fluid. Install the gasket (diaphragm) and filler cap.

PRESSURE DIFFERENTIAL VALVE

Removal

Refer to Figure 2.

1. Raise the vehicle on a hoist. Disconnect the brake warning light wire from the pressure differential valve assembly switch. **To prevent damage to the brake warning switch wire connector, expand the plastic lugs to allow removal of the shell-wire connector from the switch body.**
2. Loosen the tube nut connecting the front brake system inlet tube at the pressure differential valve assembly and disconnect the tube.
3. Disconnect the brake hydraulic lines

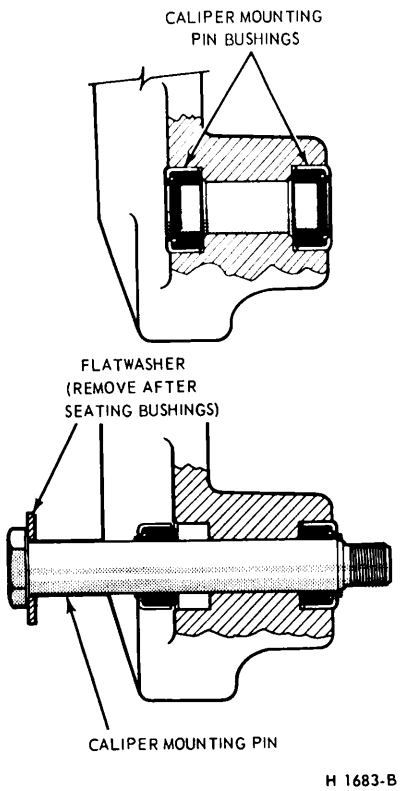

FIG. 19 Floating Caliper Mounting Pin Bushing Installation

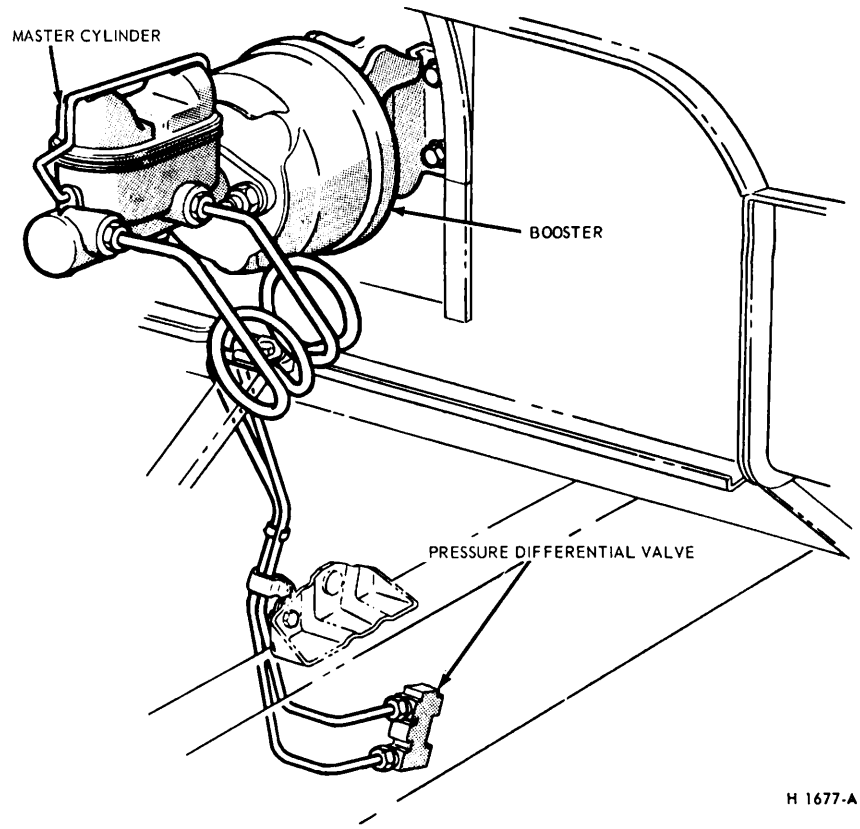

FIG. 20 Master Cylinder Installation

from the differential valve assembly.
4. Remove the screw retaining the pressure differential valve assembly to the frame side rail and remove the valve assembly.
5. If the differential valve is to be replaced, remove the brake warning lamp switch and install the switch in the new differential valve. **The pressure differential valve assembly and the brake warning lamp switch are separate units and each is serviced as a separate assembly only.**

Installation

1. Mount the pressure differential valve assembly on the frame side rail and tighten the attaching screw.
2. Connect the brake hydraulic system lines to the differential valve assembly and tighten the tube nuts securely.
3. Connect the shell-wire connector to the brake warning lamp switch. **Make sure the plastic lugs on the connector hold the connector securely to the switch.**
4. Bleed the brakes and centralize the pressure differential valve as outlined in this Section of the manual.

METERING VALVE (FLOATING CALIPERS)

The metering valve is serviced as an assembly. **No attempt should be made to disassemble or adjust the valve.**

Removal

Refer to Figure 9.

1. Remove the hydraulic tubes from the metering valve body.
2. Remove the retainer screws from the mounting bracket and remove the valve assembly.

Installation

1. Position the valve assembly to the frame and install the hydraulic tubes in the valve body. Do not tighten the tube nuts.
2. Install the retainer screws.
3. Tighten the tube nuts to specification.

BRAKE PEDAL

Removal and Installation

Refer to Part 12-01 (General Hydraulic Brake Service) for these procedures.

OVERHAUL

DISC BRAKE CALIPER—FLOATING CALIPER

Refer to Figure 21.

If the caliper assembly is leaking, the piston assemblies must be removed from the piston housing and replaced. If the cylinder bores are scored, corroded or excessive wear is evident, the piston housing must be replaced. **Do not hone the cylinder bores.** Piston assemblies are not available for oversize bores. The piston housing must be removed from the caliper for replacement.

Disassembly

1. Remove the two pins and nuts retaining the caliper to the support. Disconnect the flexible brake hose and plug the end to prevent brake fluid leakage.
2. Drain the fluid from the cylinders.
3. Position the caliper assembly in a vise. Remove the brake shoes and lining from the caliper assembly.
4. Place a 1-1/8 inch thick block of wood between the caliper and the cylinders, and apply low pressure air to the brake hose inlet. The pistons will be forced out to the wood block.
5. Remove the wood block and remove the pistons.
6. Remove the two bolts and separate the caliper from the cylinder housing.
7. Remove the piston seals from the piston bores.

Assembly

The piston seals and dust boots are not to be reused. A new set is to be used each time the caliper is assembled.

1. Lubricate the piston seals with clean brake fluid and install into the seal grooves in the cylinder bores.
2. Apply a film of clean brake fluid in the cylinder bores.
3. Lubricate the retaining lip of the dust boots with clean brake fluid and install into the boot retaining grooves in the cylinder bores.
4. Apply a film of clean brake fluid on the piston.
5. Insert the pistons into the dust boots and start them into the cylinders by hand.
6. Place a wood block over one piston and press the piston into the cylinder using care not to cock the piston as this will cause damage to the piston. Repeat for the second piston.
7. Install lining assemblies into the caliper.
8. Position the piston housing on the caliper and install the piston housing-to-caliper mounting bolts and wahers. Torque the piston housing-to-caliper mounting bolts to 155 to 185 ft.-lbs.
9. Install the flexible brake hose and torque to specifications.
10. Bleed the brake system and centralize the pressure differential valve. Refer to hydraulic system bleeding. **Do not move the vehicle after working on the disc brakes until a firm brake pedal is obtained.**

DISC BRAKE CALIPER—SLIDING CALIPER

Disassembly

1. Clean the exterior of the caliper in denatured alcohol.
2. Remove the plug from the caliper inlet port, and drain the fluid from the caliper housing.
3. Position the caliper as shown in Fig. 22 and place several shop cloths between the piston and the outer legs of the caliper.

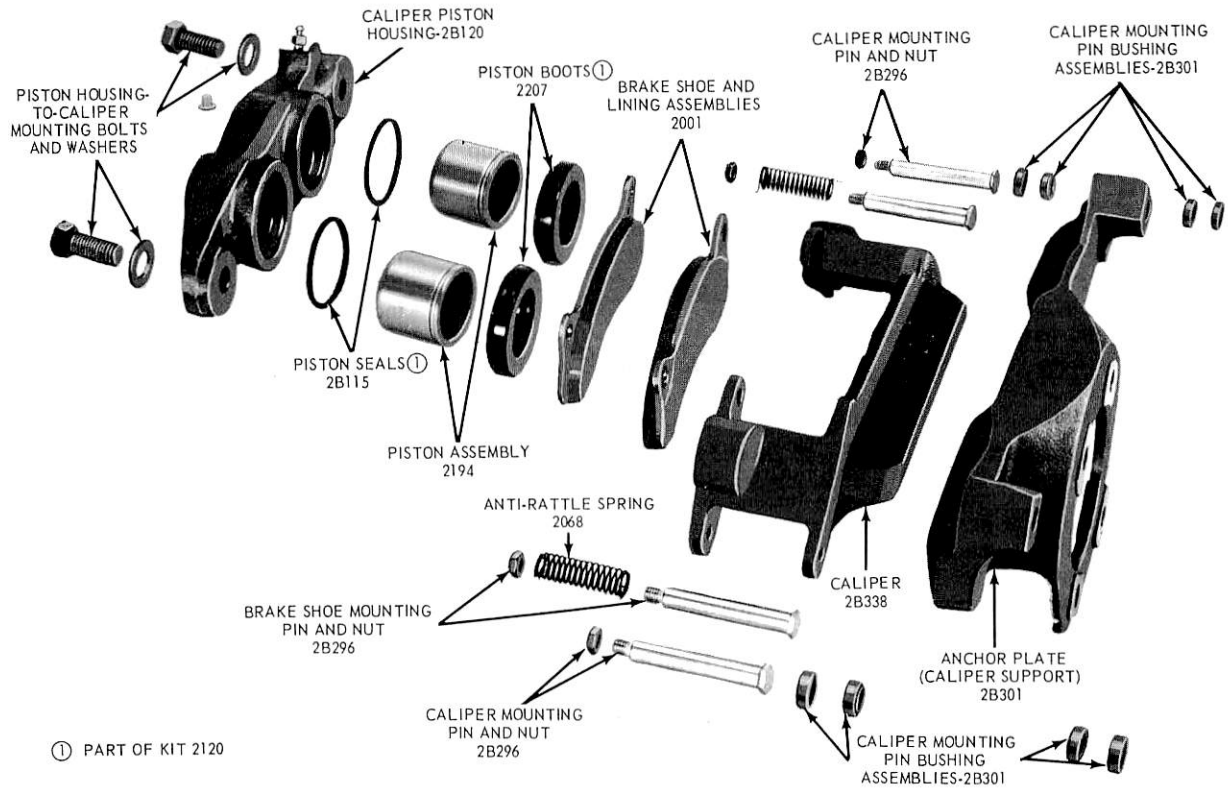

FIG. 21 Front Disc Brake Caliper Disassembled—Floating Caliper

4. Slowly and carefully apply air pressure to the caliper inlet port until the piston is removed from the caliper. **Be very careful when using air pressure to remove the piston from the caliper. If high pressures are applied, the piston may pop out with considerable force and cause personal injury. Also, be careful to avoid a spray of brake fluid.**
5. If the piston is seized or cocked and does not come out readily, release the air pressure and use a soft (brass) hammer to rap sharply on and around the end of the piston. Then, re-apply air pressure to remove the piston, following the precautions stated in Step 4.
6. Remove the boot from the piston and the seal from the caliper cylinder bore (Fig. 23). **Do not use a sharp tool to pry the piston out of the bore.**

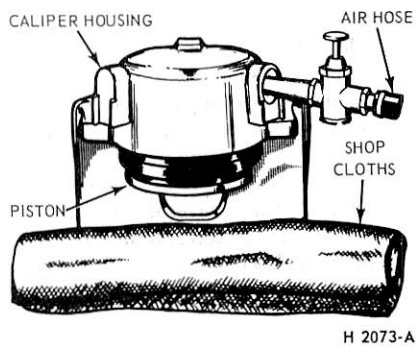

FIG. 22 Removing Caliper Piston

Cleaning And Inspection

Use a wire brush to remove any rust or corrosion from the machined surfaces of the caliper housing (**do not use a wire brush in the cylinder bore).**

Clean the caliper housing and the piston in clean denatured alcohol. Use clean, dry compressed air to clean out and dry the grooves and passages. Be sure that the cylinder bore is free of foreign matter.

Check the cylinder bore, seal groove and boot groove in the bore and the piston for damage or excessive wear. Replace the piston if it is pitted, scored or worn. If corrosion is present in the boot groove, use a wire brush carefully to clean it up.

Use a wire brush to remove any rust or corrosion from the machined surfaces of the spindle assembly.

Inspect the inner shoe anti-rattle clip, caliper support spring and caliper support key and replace, if damaged.

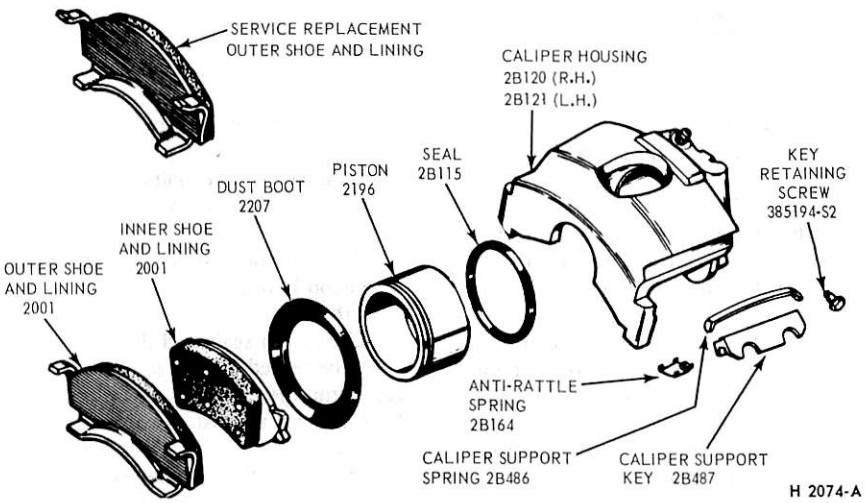

FIG. 23 Disc Brake Caliper Diassembled—Sliding Caliper

Assembly

1. Lubricate the piston seal with clean brake fluid, and position the seal in the groove in the cylinder bore.
2. Coat the outside of the piston and both beads of the dust boot with clean brake fluid and insert the piston through the dust boot so that the boot is around the bottom (closed end) of piston as shown in Fig. 24.
3. Hold the piston and dust boot directly above the caliper cylinder bore, and use fingers to work the bead of the dust boot into the groove near the top of the cylinder bore.
4. After the bead of the dust boot is seated in the groove, press straight down on the piston until it bottoms in the bore. Be careful not to cock the piston in the bore. A C-clamp (with a block of wood inserted between the clamp and piston) may be used to bottom the piston, if necessary.

DISC BRAKE ROTOR

Refinishing

Rotunda Disc Brake Tool FRE-1466-B should be used to refinish the disc brake rotors. The step-by-step resurfacing procedure provided with the tool must be adhered to.

A maximum of 0.010 inch material may be machined equally off each surface (A and B, Fig. 25). If rotor thickness falls below the minimum thickness shown on each rotor, it must be replaced.

The finished braking surfaces of the rotor must be flat and parallel within 0.001 inch; lateral runout must not exceed 0.003 inch total indicator reading, on the inboard surface at a 6-inch radius, and the surface finish of the braking surfaces are to be 15-80 micro inches.

FIG. 24 Piston and Dust Boot Assembly

DUAL-BRAKE SYSTEM MASTER CYLINDER

Refer to Figure 26.

The master cylinder must be removed from the vehicle to be overhauled.

When a repair is necessary on the master cylinder, it is required practice during the warranty period to replace the cylinder as a unit instead of overhauling the cylinder with a service repair kit.

Disassembly

1. Clean the outside of the master

cylinder and remove the filler cap and gasket (diaphragm). Pour out any fluid that remains in the cylinder.

2. Unscrew the piston stop from the bottom of the cylinder body. Remove the O-ring seal from the piston stop. Discard the seal.
3. Remove the snap ring (Fig. 27) retaining the primary and secondary piston assemblies with the cylinder body.
4. Remove the primary piston assembly from the master cylinder. Discard the primary piston assembly.

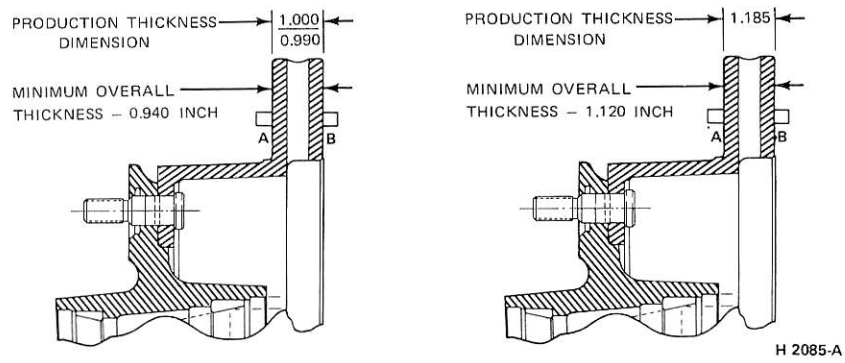

FIG. 25 Disc Brake Rotor Service Limits

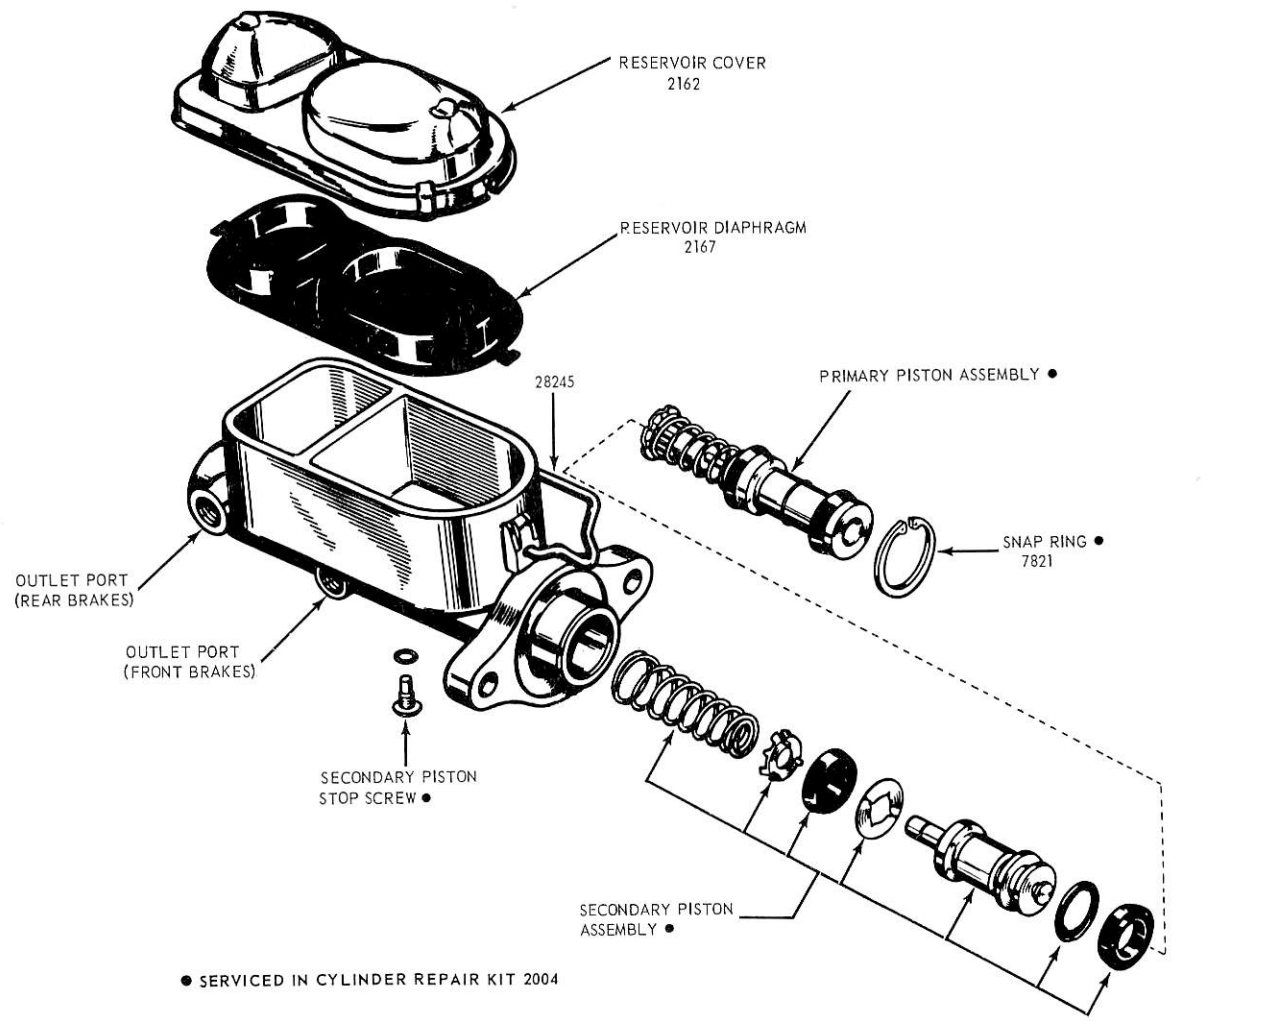

5. Apply an air hose to the rear brake outlet of the port of the cylinder body and blow the secondary piston out of the cylinder body.
6. Remove the return spring and cup protector from the secondary piston. Discard the piston.

Inspection and Repair

1. Clean all parts in clean isopropyl alcohol, and inspect the parts for chipping, excessive wear of damage. Replace them as required. **When using a master cylinder repair kit, install all the parts supplied.**
2. Check all recesses, openings and internal passages to be sure they are open and free from foreign matter. Use the air hose to blow out dirt and cleaning solvent. Place all parts on a clean pan or paper.
3. Inspect the hydraulic master cylinder bore for signs of etching, pitting or rust. Replacement of the master cylinder will be required if any of these conditions exist.

Assembly

1. Dip all the parts except the cylinder body in clean brake fluid of the specified type.
2. Assemble the spring and cap protector to the secondary piston.

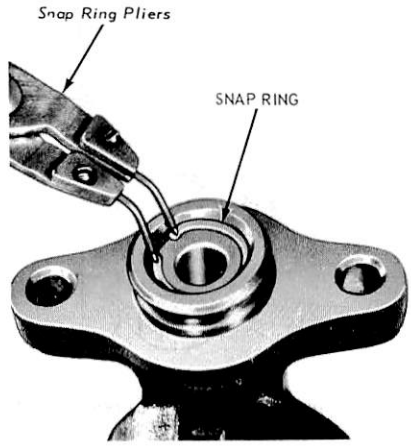

FIG. 27 Removing Snap Ring—Typical

3. Install the secondary piston assembly in the master cylinder.
4. Install a new O-ring on the piston stop, and start the stop into the cylinder body.
5. Install the primary piston assembly in the master cylinder. Push the primary piston inward and tighten the secondary piston stop to retain the secondary piston in the bore.
6. Position the stop plate and snap ring on the primary piston. Depress the primary piston and install the snap ring in the cylinder body.
7. Bleed the master cylinder.

Bleeding the Master Cylinder

Before the master cylinder is installed on the vehicle, the unit should be bled.

1. Support the master cylinder body in a vise, and fill both fluid reservoirs with the specified brake fluid.
2. Loosely install plugs in the front and rear brake outlet bores. Depress the primary piston several times until air bubbles cease to appear in the brake fluid.
3. Tighten the plugs and attempt to depress the piston. **The piston travel should be restricted after all air is expelled.**
4. Remove the plugs. Install the cover and gasket (diaphragm) assembly, and make sure the cover retainer is tightened securely.

DESCRIPTION AND OPERATION

AIR SUPPLY SYSTEM

The air supply system is used with the full air brake system. In the full air system, air pressure is applied directly to the shoes through a diaphragm and mechanical linkage.

The air supply system consists of the compressor, reservoirs, governor, low pressure indicator and dash gauge.

The compressing action of the compressor is controlled by the governor. When reservoir air pressure reaches 118-126 pounds, the governor cuts out the compressor. When reservoir pressure drops to 98-104 pounds, the governor allows the compressor to cut in again. When reservoir air pressure drops below 58-65 psi, the low pressure indicator valve closes an electrical circuit to a warning buzzer.

On some models, an automatic moisture ejector valve replaces the drain cock on the air system reservoir. When reservoir pressure drops slightly, the valve opens and ejects any moisture which has collected in the sump.

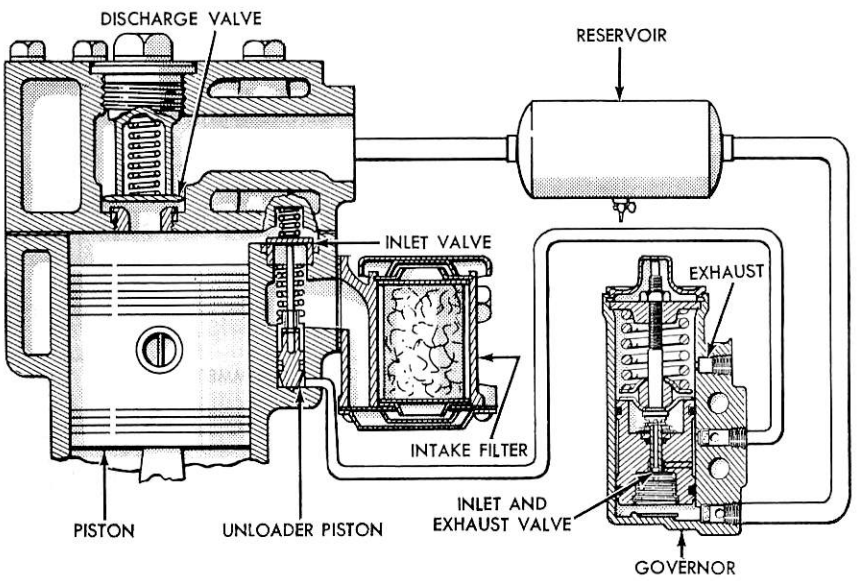

FIG. 1 Air Compressor Operation

COMPRESSOR

A typical compressor is a two-piston air pump with an engine pressure lubricating system and water cooled cylinder head and block (Fig. 1). Other compressors are furnished, depending on the engine installation. These may be single piston or air-cooled. The principle of operation is, for practical purposes, the same for all however.

GOVERNOR

The governor (Fig. 2), operating in conjunction with the compressor unloading mechanism, automatically controls the air pressure in the air brake or air supply system between the desired, predetermined maximum and minimum pressures. The compressor runs continually while the engine runs, but the actual compression of air is controlled by the governor which stops or starts compression when the maximum or minimum reservoir pressures are reached. The D-2 governor has a piston upon which air pressure acts to overcome the pressure setting spring and control the inlet and exhaust valve to either admit or exhaust air to or from the compressor unloading mechanism.

Connections in this system are to the reservoir and compressor unloading ports. There also is an exhaust port.

AUTOMATIC MOISTURE EJECTOR VALVE

The automatic moisture ejector valve (Fig. 3) ejects moisture and contaminants from the air system reservoir. It operates automatically and requires no manual assistance or control lines from other sources.

The automatic moisture ejector valve has a die cast aluminum body and cover and is mounted in the bottom of the air system reservoir.

SERVICE BRAKE SYSTEM

The braking system (Figs. 4 through 11) consists of the foot control valve (Fig. 5), the brake chambers, brake shoe actuating mechanism, and quick release valves (Fig. 12).

FOOT CONTROL VALVE

The foot control valve delivers air pressure from the air supply system to the brake air service chambers.

The distance the brake treadle or pedal is depressed regulates the amount of compressed air delivered by the foot control valve to the brake chambers. The amount of air, in turn, determines the braking force applied to the shoes by the slack adjusters or wedges.

BRAKE SERVICE AIR CHAMBER

Compressed air, admitted to the brake chamber by the foot control valve, enters the chamber behind a diaphragm which forces the push plate and push rod outward (Fig. 13). On cam-type air brakes, the outward movement of the push rod rotates the slack adjuster which in turn rotates the brake camshaft and cam forcing the shoes against the drum. On wedge-type air brakes, the outward movement of the push rod forces a wedge between the shoe plungers forcing the shoes against the drum.

QUICK RELEASE VALVES AND RELAY VALVE

The quick release valve (Fig. 4) reduces the time required to release the brakes by hastening the exhaust of air from the brake chambers. The valve body contains a spring-loaded diaphragm so arranged as to permit supply pressure from the control valve to flow through the release valve to the brake chambers in one direction. When supply pressure is reduced, the air, which has passed through, is permitted to escape rapidly through the exhaust port.

The quick release valve is used with both front and rear brake chambers, or with front chambers only as in the case of a LT-Series truck.

On a LT-Series truck, the relay valve is used in place of the rear quick release valve (Fig. 14). The relay valve functions somewhat the same as the quick release valve, except that it services four rear brake chambers on a LT-Series truck instead of two. The relay valve is also more sensitive to the action of the control valve in that it can assume a balanced position as well as apply and release.

TRACTOR-TRAILER AIR BRAKE SYSTEM

Tractor-trailer air brake equipment is available as a regular production option. The following items are included in the package.

HAND CONTROL VALVE

The hand operated brake application valve (Fig. 15) is mounted on the steering column. It controls the application of the trailer brakes independent of the tractor brakes.

DOUBLE CHECK VALVE

The double check valve is a shuttle type valve which is connected between the hand operated and foot operated brake control valves. The double check valve prevents air from exhausting through one of the brake control valves while the other is being applied.

In a typical installation (Fig. 16), the double check valve is connected to a reservoir pressure manifold mounted to the engine side of the dash panel. The pressure indicator valve also ties into this manifold from the passenger side.

MANUAL EMERGENCY VALVE

The manual emergency valve is mounted under the edge of the instrument panel. This is a two-way valve by which the operator manually controls the operation of the tractor protection valve for either normal or emergency operation of the brakes.

TRACTOR PROTECTION VALVE

A manually and/or automatically operated push-pull type tractor protection valve (Figs. 17 and 18) which works in conjunction with the trailer emergency break-away valve (Fig. 19) is standard equipment on all air brake models equipped with the optional tractor package.

RELAY EMERGENCY VALVE

The relay emergency valve is located on the trailer near the trailer reservoir. During normal operation it charges the trailer reservoir and applies and releases the trailer brakes in unison with the tractor brakes. During emergency operation, or in the case of trailer break-away, the relay emergency valve automatically applies the trailer brakes.

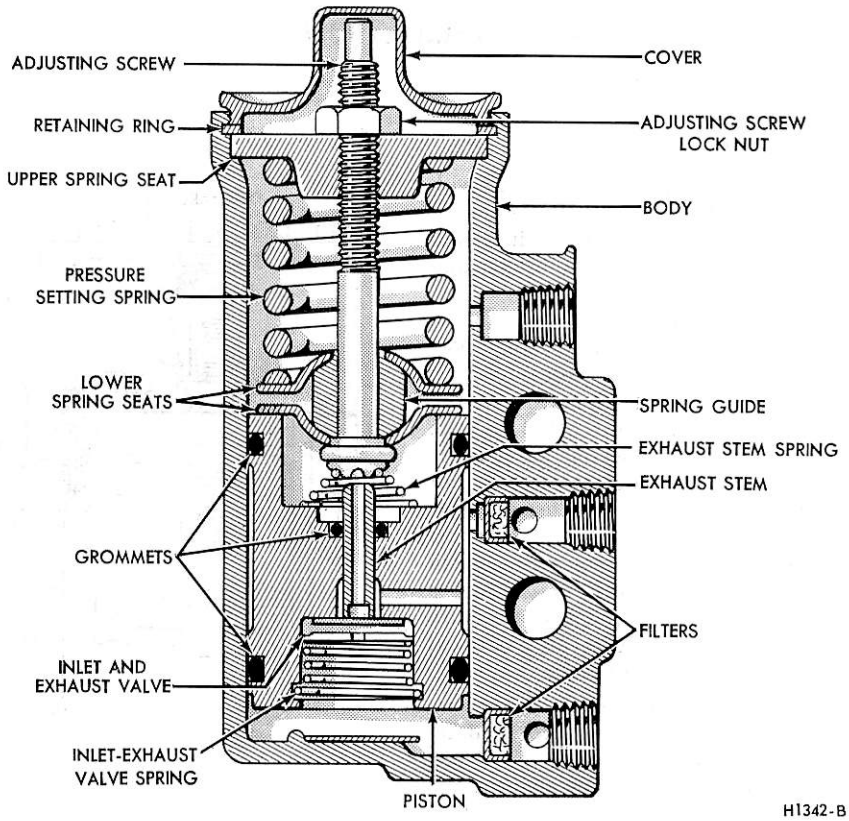

FIG. 2 Compressor Governor

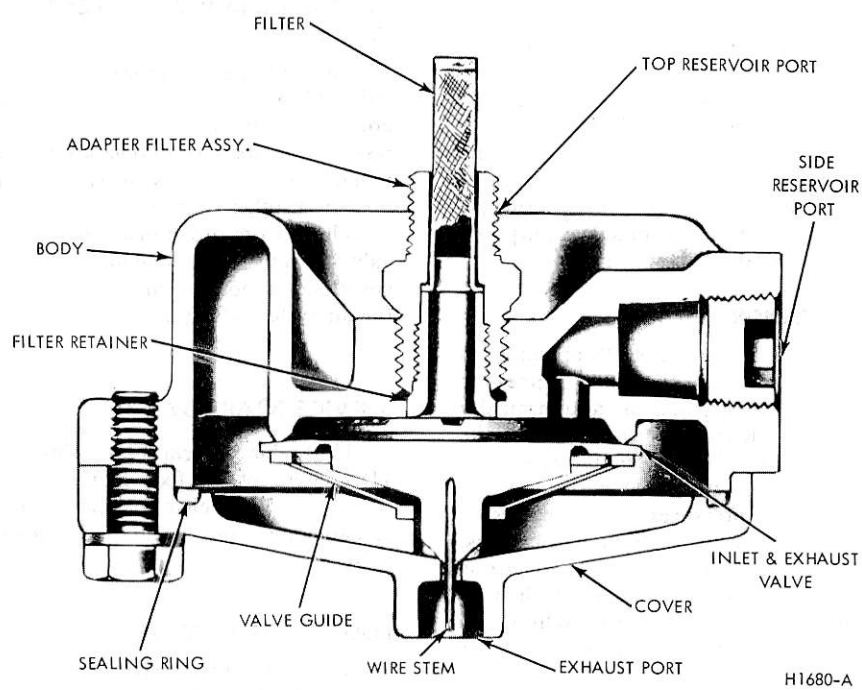

FIG. 3 Automatic Moisture Ejector Valve

HOSE HANGERS AND CONNECTORS

The trailer brake hoses (emergency line and service line) are suspended from the rear of the cab, above the rear cab window, by coil springs (Figs. 20 and 21). When the trailer is not in use, the connectors are hung on brackets at either side of the rear of the cab.

FRONT WHEEL LIMITING VALVE

The two-way limiting valve instantly limits air pressure delivery at the front wheel brake chambers according to road and load conditions and while the truck is in motion. This limited pressure at the front brakes permits the rear brakes to function with greater force than the front brakes.

The limiting valve is mounted on the dash. An air line from the delivery port of the brake control valve connects to the inlet port of the limiting valve. Another air line connects the delivery port of the limiting valve to the front quick release valve. The other two side ports of the limiting valve are connected to the front brake chambers.

The limiting valve, besides providing for a 50 percent reduction of front wheel braking pressures, also serves as a quick release valve upon release of the brakes when required by unusual road and load conditions.

DIAGNOSIS AND TESTING

AIR SUPPLY SYSTEM OPERATING TESTS

Before performing any of the following tests, operate the engine until the air pressure builds up to 90 psi. With the air brake system charged, open the drain cocks in each reservoir. Close the drain cocks after all moisture is drained from the reservoirs. Some models have automatic moisture ejector valves and do not require manual draining.

LOW PRESSURE INDICATOR

Exhaust the brake system pressure and observe the pressure at which the warning buzzer sounds. The contacts in the indicator should close the circuit to the buzzer, when reservoir pressure is between 58 psi minimum and 65 psi maximum. If the buzzer does not start to sound within this pressure range during discharge, or if a sounding buzzer does not stop within this pressure range during the pressure buildup, the electrical connections are loose or the indicator valve is not operating properly.

RESERVOIR SAFETY VALVE

To determine if the safety valve is operative, pull the exposed end of the valve stem. If the safety valve does not blow off when the stem is pulled, the valve ball is probably stuck in its seat. In such a case, remove and disassemble the valve for cleaning.

AUTOMATIC MOISTURE EJECTOR VALVE

With the system charged, make several foot valve applications and note each time an application is made if an exhaust of air occurs at the exhaust port of the drain valve. If no air comes out, push the wire stem. If no air comes out, the filter is plugged and the valve should be removed and cleaned.

Because the automatic moisture ejector valve functions as reservoir pressure is reduced, excessive leakage in the system will cause constant exhausting of the valve.

GOVERNOR

With the engine running, build up air pressure in the system, and observe at what pressure reading on the dash gauge the pressure stops climbing. This is the point of governor cutout which should be between 118 and 126 pounds.

With the engine still running, slowly reduce the air pressure in the system by applying and releasing the brakes. Observe the pressure reading on the dash gauge at the point where the pressure starts to build up again. This is the point of governor cut-in which should be between 98 and 104 pounds.

If the governor does not cut the compressor in and out according to these specifications, adjust the governor pressure settings. Before adjusting the governor, check the accuracy of the dash gauge with a test gauge.

Check Pressure Build-Up

With the engine running at fast idle speed, observe the time required to raise system pressure from 50 to 90 pounds. If more than five minutes is required, perform the leak tests as outlined in the following paragraphs.

Also check for low engine idle speed, a slipping compressor drive belt, excessive carbon in the compressor cylinder head, or a worn out air compressor.

AIR SUPPLY SYSTEM LEAK TESTS

COMPRESSOR

With the engine stopped, discharge valve leakage can be detected by carefully listening at the compressor for the sound of escaping air. With air pressure applied to the unloader cavity (with governor cut-out), remove the air filter or the air pick up tube on SD V-8 engines and check for air leaks by squirting oil around the unloader plunger and stem. If excessive air leaks are found, replace the unloader mechanism.

GOVERNOR

With the governor in the cutout position, test for leakage at the exhaust valve by applying soap suds to the exhaust vent in the body.

With the governor in the cut-in position, test for leakage of the inlet valve by applying soap suds to the exhaust vent in the body.

In either of the foregoing tests, leakage in excess of 1 inch soap bubble in three seconds indicates the governor should be replaced.

RESERVOIR SAFETY VALVE

Coat the end of the safety valve with soap suds. Leaks causing not more than a 3 inch soap bubble in three seconds are permissible.

AUTOMATIC MOISTURE EJECTOR VALVE

With the system charged and pressure stabilized in the system, there should be no leaks at the drain valve exhaust. A constant slight exhaust of air at the drain valve exhaust could be caused by excessive leakage in the air brake system.

AIR BRAKE SYSTEM OPERATING TESTS

Some of the air brake system components vary slightly from one vehicle model to another in design or location. However, all components are essentially the same in principle and service procedure.

STOP LIGHT SWITCH CHECK

With all air pressure exhausted from the air brake system, start the engine and move the brake valve to the applied position. stop lights should light before the dash gauge registers 5 psi pressure. Release the brakes.

QUICK RELEASE VALVE AND RELAY VALVE

With the air brake system fully charged, apply the brakes. Inspect the brake action on the wheels controlled by the quick release valve or relay valve in question. The brakes should apply promptly. Release the brakes and inspect to be sure that the air pressure is exhausted rapidly from the exhaust port. Be sure the exhaust port is not restricted.

AIR BRAKE SYSTEM LEAK TESTS

With engine stopped and reservoir charged to governor cutout pressure of 118 -126 psi, the rate of pressure drop should not exceed 2 psi per minute with the service brakes released and spring (parking) brakes applied; or, 3 psi per minute after the initial pressure drop with service brakes fully applied and spring (parking) brakes released.

BRAKE CHAMBERS

With the brakes fully applied, coat the clamp ring and bolt flanges holding the diaphragm in place with soap suds. No leaks are permissible.

QUICK RELEASE VALVE

With brakes applied, coat the exhaust port with soap suds to detect leakage. Leakage is not permissible.

RELAY VALVE

With all air pressure exhausted from the air brake system, start the engine and move the brake valve to the applied position. Stop lights should light before the dash gauge registers 5 psi pressure. Release the brakes.

With the brakes **released,** coat the exhaust port with soap suds and observe the leakage.

With the brakes fully **applied,** coat the exhaust port with soap suds and observe the leakage.

Leakage in either of the foregoing tests should not exceed a 3 inch soap bubble in three seconds.

ADJUSTMENTS

AIR COMPRESSOR DRIVE BELT ADJUSTMENT

If the reservoir pressure will not rise to normal or rises too slowly, a slipping compressor drive belt could be the cause.

VERTICALLY-MOUNTED COMPRESSOR ADJUSTMENT

1. Loosen the bolts that attach the compressor to the mounting bracket (Fig. 22).

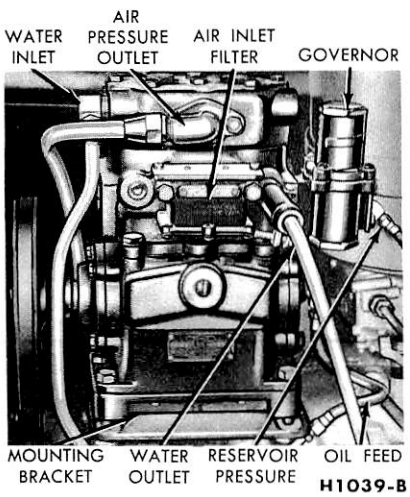

FIG. 22 Air Compressor—Vertically Mounted

2. Slide the compressor away from the fan pulley until a 1/2 inch belt deflection (with thumb pressure) is established.
3. Tighten the compressor attaching bolts.

SIDE-MOUNTED COMPRESSOR ADJUSTMENT

1. Loosen the idler pulley bracket pivot bolt and adjusting bolt (Fig. 23).

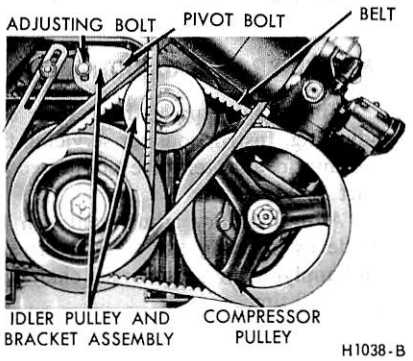

FIG. 23 Belt Adjustment on Side-Mounted Compressor

2. Pivot the idler bracket and pulley against the belt until 1/2 inch belt deflection (with thumb pressure) is established.
3. Tighten the adjusting bolt and pivot bolt with the idler bracket and pulley assembly in the properly adjusted position.

GOVERNOR ADJUSTMENT

Before adjusting the pressure settings of the governor, determine the accuracy of the dash gauge by checking gauge readings against an accurate test gauge. The cut-in and cut-out setting is made at the adjusting screw (Fig. 2).

1. With the engine running, build up air pressure in the system and observe the pressure registered by the dash gauge.
2. If the pressure build-up continues beyond 125 pounds before the governor cuts out, remove the cover from the top of the governor and loosen the lock nut. Turn the adjusting screw clockwise to lower the cut-out pressure and counterclockwise to increase the cut-out pressure. After adjusting the cut-out pressure, tighten the adjusting screw lock nut and install the cover. **The air pressure range between cut-out pressure (maximum) and cut-in pressure (minimum) is fixed at about 20-25 pounds and cannot be adjusted.**

AIR RESERVOIR SAFETY VALVE ADJUSTMENT

The air reservoirs are connected into the air brake system. Drain cocks are provided at the bottom of each reservoir. A safety valve is installed on one of the reservoirs.

When servicing the reservoirs, removal or installation of the air tube between the reservoirs can be made by loosening the reservoirs from the frame.

The safety valve is set to relieve pressure at 150 psi. It is non-adjustable and must be replaced if excessive system pressures are indicated (above the 150 psi setting).

AIR LINES

Any portion of the tubing that is kinked, or pinched, should be replaced to prevent restrictions.

When repairs are performed, use the tubing conforming to specification. A new insert (Fig. 24) should be used in order to prevent leaks or collapsing of the tubing. The tubing end must be cut square and also bottomed against the insert while tightening the nut.

FOOT CONTROL VALVE ADJUSTMENT

To determine if the brakes are applying properly, proceed as follows:

1. Install a pressure gauge anywhere in the circuit between the control valve and the brake chambers, or install the gauge in one of the extra brake service ports (upper row of ports).
2. Fully depress the brake treadle. The test gauge reading should approximate reservoir pressure as indicated by the dash gauge.
3. Adjust the stop, button on the suspended pedal (Fig. 5) to eliminate pedal free travel.

SLACK ADJUSTER ADJUSTMENT—CAM OPERATED BRAKES

Apply the brakes and measure the travel of the brake chamber push rod (Fig. 13). If equipped with a Maxi brake unit, the minimum air pressure should be 90 psi while measuring the travel.

The travel should be kept to the minimum possible without causing the brakes to drag. The maximum travel should not exceed the dimensions listed in the specifications. **Adjustment of the yoke on the brake chamber push rod should not be changed. When new, the yoke is adjusted so that the slack adjuster brake chamber push rod angle is slightly greater than 90 degrees when the brakes are properly adjusted and the brakes are applied. Brake lining wear will not change this angle as long as the slack adjusters are kept adjusted to compensate for lining wear.**

FRONT

This procedure applies only to trucks equipped with S-cam operated brakes.

A push rod travel, that reaches or exceeds the maximum listed in the Brake Chamber Push Rod Adjustment table in specifications indicates need of adjustment. Turn the adjusting screw clockwise until the push rod travels 3/4 inch in going from released to fully applied position (Fig. 13). When making the adjustment, turn the screw in quarter turns.

REAR

This procedure applies to vehicles equipped with either standard or Maxi-brake S-cam type slack adjusters.

A push rod travel, that reaches or exceeds the maximum listed in the Brake Chamber Push Rod Adjustment table in specifications indicates need of adjustment. Depress the lock sleeve and turn the hexagon head of the wormshaft clockwise until the push rod travels one inch in going from released to fully applied position (Fig. 25). Be sure that the lock sleeve comes back out and engages the hexagon head of the wormshaft so as to lock the adjustment.

When adjusting either front or rear slack adjusters, raise the wheels and make certain that there is no brake drag.

WEDGE BRAKE ADJUSTMENT

The wedge type air brakes are self adjusting. Instructions for servicing the automatic adapters are contained in Part 12-44.

A preliminary adjustment can be made by rotating the wheels forward and applying air to the brake chambers 25 or 30 times.

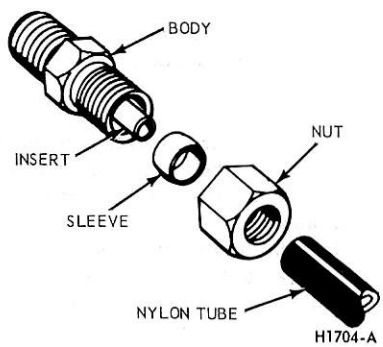

FIG. 24 Air Line Coupling

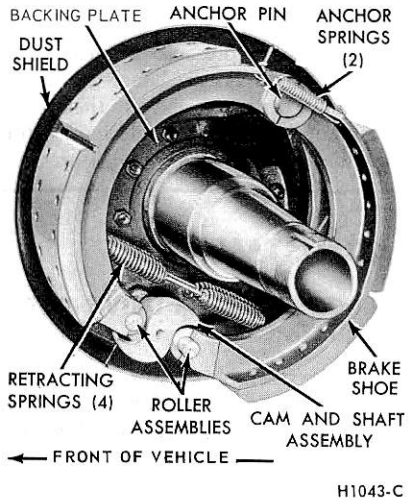

FIG. 25 Rear Brake Assembly—S-Cam (Eaton)

REMOVAL AND INSTALLATION

AIR COMPRESSOR

VERTICALLY-MOUNTED COMPRESSOR—WITH GAS—ENGINE VEHICLES

Removal

Depending upon the particular vehicle model and engine, compressors are mounted in various locations. Removal and installation procedures differ between vertically mounted units and side mounted units. These instructions apply generally to liquid-cooled compressors, but air-cooled installations are similar, other than coolant connections.

1. Open the reservoir drain cocks to exhaust air pressure from the system.
2. Drain the cooling system.
3. At the compressor, disconnect the compressor air outlet line, the water inlet and outlet lines and the oil feed and oil return lines (Fig. 22).
4. Since the reservoir pressure hose is difficult to remove at the governor, disconnect the hose at the fitting on the opposite end. If the hose is to be replaced, disconnect it from the governor after the compressor has been removed.
5. Remove the four compressor to base plate bolts, slide the compressor inward on the base plate and disengage the drive belt; then remove the compressor.

Installation

1. Transfer the pulley, Woodruff key and attaching nut to the new compressor.
2. Transfer the air outlet elbow and gasket, the water inlet and outlet fittings, and the oil inlet and outlet fittings to the new compressor. Apply sealer to all these parts.
3. Transfer the governor and gasket to the new compressor (two attaching bolts). Apply sealer. If the reservoir pressure hose is to be replaced, connect it to the governor at this time.
4. Transfer the air inlet filter and gasket to the new compressor (two retaining bolts). Apply sealer.
5. Position the compressor on the base plate and engage the drive belt to the pulley.
6. Install the four attaching bolts, slide

the compressor away from the fan pulley until a 1/2 inch belt deflection is obtained, and tighten the bolts.
7. Connect the compressor air outlet line, the water inlet line and the water outlet line to the compressor. Connect the oil feed and the oil return lines to the compressor.
8. Connect the hose from the governor to the fitting on the reservoir pressure line.
9. Fill the cooling system, close the reservoir drain cocks, start the engine and check for air, oil or coolant leaks, if applicable.

SIDE-MOUNTED COMPRESSOR—WITH GAS—ENGINE VEHICLES

Removal
1. Drain the cooling system, and open the reservoir drain cocks to exhaust air pressure from the system.
2. Loosen the idler pivot bolt and adjusting bolt, and remove the compressor belt (Fig. 23).
3. At the compressor, disconnect the air outlet line, and the water inlet and outlet lines.
4. Disconnect the reservoir pressure line from the governor.
5. Remove the bracket bolt at the cylinder head and the bracket bolt and washer at the manifold, then remove the bracket between the exhaust manifold and the cylinder head.
6. If equipped with power steering, remove the attaching bolt nut and lockwasher from the clip at the frame side rail. Also, remove the power steering hose retaining bolt, nut, and lockwasher at the frame crossmember and set the hoses out of the way.
7. Remove the two front compressor to base plate attaching bolts. The clearance between the compressor base plate and the engine mount is very small.
8. Remove the three remaining bolts.
9. Remove the air compressor from underneath the vehicle in a rearward direction and discard the base gasket.

Installation
1. Remove the compressor pulley cotter pin and Woodruff key, then pull the pulley off the shaft with a puller.
2. On C-Series vehicles, install the compressor pulley on the replacement compressor at this point. On all other models with a side-mounted compressor, do not install the pulley until after the compressor has been installed.
3. Transfer the air outlet and the water inlet and outlet fittings to the replacement compressor. Coat the threads with sealer.
4. Transfer the air inlet strainer and gasket to the replacement compressor (two attaching bolts). Apply sealer.
5. Transfer the governor and gasket to the new compressor (two attaching bolts). Apply sealer.
6. Clean the compressor base and cylinder block base plate (Fig. 26).
7. Apply sealing compound to both sides of base gasket.
8. Install pilot studs in the two rear bolt holes shown in Fig. 5 and position the base gasket to the base plate over the studs. From underneath the vehicle, mount the compressor to the pilot studs and install three attaching bolts. Remove the pilot studs and install the remaining two bolts.
9. If equipped with power steering, position the power steering hose at the frame crossmember and install the clip retainer, bolt, lockwasher, and nut.
10. Connect the water outlet line to the compressor.
11. Position the power steering tube clips at the frame side rail and secure with bolt, lockwasher and attaching nut.
12. Connect the water inlet line to the compressor.
13. On all except C-Series, loosen the two power steering belt adjustment bolts and loosen the belt to provide clearance for installation of the compressor pulley. Install the compressor pulley to the shaft and secure with the nut and cotter pin.
14. Position the power steering belt on the pulleys and adjust the belt tension.
15. Position the air compressor belt on the pulleys and adjust the belt tension (Fig. 23).
16. Connect the air outlet line to the compressor.
17. Connect the reservoir pressure line at the governor.
18. Fill the cooling system, close the air reservoir drain cocks, and build up pressure in the system.

AIR COMPRESSOR WITH FORD DIESEL ENGINES

Removal
1. On C-Series vehicles, release the cab locks and tilt the cab forward.
2. Drain the cooling system. Open the air reservoir drain cocks to exhaust air pressure from the system.
3. Loosen the air outlet line at the air compressor (Fig. 27), and allow the air to escape. Disconnect the air outlet line. Disconnect the governor air line at the air compressor governor.
4. Disconnect the water supply and return lines at the air compressor (Fig. 28).
5. Disconnect the oil supply and oil return lines at the air compressor (Fig. 28).
6. Remove the three compressor mounting bolts. Disengage the drive gear, and remove the compressor.

Installation
1. Position the air compressor on the mounting bracket attached to the engine front support plate. Engage the drive gear.
2. Connect the oil supply and return lines to the compressor (Fig. 28).
3. Connect the water supply and return lines to the compressor.
4. Connect the governor air line and the air outlet line to the compressor (Fig. 27).
5. Fill and bleed the cooling system.
6. Close the air reservoir drain cocks.
7. Start the engine and check for air, coolant and oil leaks.
8. On C-Series, tilt the cab rearward and secure with the cab locks.

AIR COMPRESSOR—CUMMINS DIESEL NH SERIES ENGINES

The air compressor is flange mounted to the accessory drive and is driven by a splined-sleeve type drive coupling from the accessory drive shaft. The fuel pump is flange mounted to the rear of the air compressor and must be removed before the air compressor can be removed.

The following procedures and illustrations are for the standard Bendix Westinghouse unit, but are typical of the Cummins unit which is mounted in the same manner.

Removal
1. Unlock the tilt cab on W-Series trucks. Partially drain the cooling system, and exhaust the air reservoirs.
2. Disconnect the throttle linkage and lines from the fuel pump, and remove the fuel pump from the air compressor as described in Group 23.
3. Remove the rubber coupling from the drive unit (Fig. 29).
4. Remove the two governor-to-compressor attaching screws, and position the governor out of the way.
5. Disconnect the air compressor oil inlet line at the engine block (Fig. 30).
6. Remove the oil return tube from the bottom of the compressor and the engine block.

7. Disconnect the water inlet and outlet lines and the air inlet and outlet lines from the compressor (Figs. 29 and 30).
8. Remove the two nuts and lockwashers that hold the compressor to the support bracket, and the four cap screws and lockwashers that hold the compressor to the accessory drive (Fig. 29).
9. Remove the compressor and the splined accessory drive coupling (Fig. 31). Discard the old gasket.
10. If the compressor is to be replaced:
    a. Remove the compressor drive gear attaching nut, then remove the drive gear from the compressor crankshaft using a universal puller (Fig. 31).
    b. Remove the attaching nut and the fuel pump drive gear from the rear end of the compressor crankshaft.
    c. Remove the water inlet and outlet fittings, air outlet fitting, and the oil return fitting (Figs. 29, 30 and 31).
    d. Remove the air inlet housing and screen (Fig. 31).
    e. Remove the oil inlet line from the compressor drive and fuel pump flange.

Installation

1. If the compressor is being replaced:
    a. Install the oil inlet line on the fuel pump flange.
    b. Install the air inlet housing and screen (Fig. 31).
    c. Install the water inlet and outlet fittings, air outlet fittings, and the oil return fitting (Figs. 29, 30 and 31).
    d. Install the fuel pump drive gear and attaching nut to the rear of the compressor crankshaft.
    e. Install the compressor drive gear and retaining nut.
2. Assemble the splined accessory drive coupling to the compressor drive gear (Fig. 31), and mount the compressor to the accessory drive, using a new gasket. Install and tighten the four cap screws and lockwashers (Fig. 29).
3. Attach the compressor to the support bracket with two nuts and lockwashers.
4. Connect the water inlet and outlet lines (Fig. 30) and the air inlet and outlet lines to the compressor (Figs. 29 and 30).
5. Connect the air compressor oil return tube at the bottom of the compressor and at the engine cylinder block (Fig. 30).
6. Connect the air compressor oil inlet line to the engine block.
7. Mount the governor to the compressor, and install the two governor-to-compressor attaching screws (Fig. 29).
8. Install the fuel pump to the compressor rear flange with a new gasket and rubber coupling in position (Figs. 29 and 31), then connect the throttle linkage and lines as described in Group 23.
9. Fill the cooling system, and charge the reservoirs.

AIR COMPRESSOR—CUMMINS DIESEL V-6 ENGINES

The Cummins air compressor is used on vehicles equipped with V-6 engines. The compressor is flange mounted to an accessory gear case which is located at the rear of the engine between the two cylinder banks. The unit is driven by a gear which is keyed to the compressor crankshaft, and which enters the accessory gear case where it is driven by the camshaft gear. The fuel pump is flange mounted to the front of the air compressor and must be removed before the air compressor can be removed.

Removal

On W-Series trucks, unlock the tilt cab. On Wand LN-Series trucks, the air intake system components have to be removed to obtain access for compressor removal.

1. Disconnect the air intake duct from the air cross-over manifold (Fig. 32).
2. Loosen the hose clamps on the cross-over manifold connection hose.
3. Loosen the compressor air intake hose at the air cross-over manifold and at the compressor.
4. Remove the attaching bolts and the right hand air cross-over manifold from the intake manifold.
5. Disconnect the throttle linkage and lines from the fuel pump, and remove the fuel pump from the front of the compressor as described in Group 23.
6. Drain the cooling system and exhaust the air reservoirs.
7. Disconnect the air outlet line from the compressor.
8. On L-and LT-Series trucks, loosen the compressor air intake hose clamps at the main intake duct and at the compressor.
9. On L-, LT-and LN-Series trucks, remove the floor pan cover at the gear shift lever to obtain access to the line connections and the rear of the compressor.

   On W-Series trucks, this access is obtained by tilting the cab at the beginning of the removal procedure.
10. Disconnect all air lines at the governor.
11. Disconnect the water lines at the air compressor, the cylinder block, and at the water crossover connection.
12. Unclamp any water or air lines as necessary to provide clearance for compressor removal.
13. On L-, LT-and LN-Series trucks, remove the water crossover pipe from the rear of the cylinder heads in order to gain access to the accessory drive rear support plate. On W-Series trucks, it is not necessary to remove the crossover pipe because the crossover pipe goes over the top of the accessory gear case as shown in Fig. 33.
14. Remove the bolts and lockwashers that secure the rear support plate and the compressor to the accessory gear case. Remove the rear support plate from the rear side of the gear case (Fig. 33), and remove the compressor from the front side of the gear case.

Installation

1. Clean the gasket material from the compressor, gear case, and accessory drive rear support plate.
2. Position the air compressor with a new gasket to the front side of the gear case so that the timing marks on the air compressor drive gear are aligned with the marks on the camshaft gear (Fig. 33). Be sure that the gears mesh properly.
3. Position the accessory drive rear support plate with a new gasket to the rear side of the gear case, then secure the support plate and air compressor to the gear case with the lockwashers and attaching bolts.
4. On L-, LT-and LN-Series trucks, clean the gasket material from the water crossover pipe and the rear of the cylinder heads. Position the crossover pipe to the cylinder heads with new gaskets and install the attaching bolts.
5. Connect the two water lines (compressor-to-cylinder block and compressor-to-water crossover connection).
6. Connect the main air outlet line to the compressor.
7. Connect to the governor all air lines that were disconnected during removal.
8. On L-and LT-Series trucks, connect the compressor air intake hose and secure with two clamps.
9. Secure any water to air line-to-sheet metal clamps that were disconnected during removal.
10. On L-, LT-and LN-Series trucks,

install the floor pan cover at the gear shift lever.

11. Clean the gasket material from the pump mounting surface, position a new gasket, install the fuel pump to the front side of the compressor, and connect the throttle linkage and lines as described in Group 23.
12. On L-and LT-Series trucks, fill the cooling system, charge the reservoirs and check for leaks.

On W-and LN-Series trucks, first install the air intake system components as outlined in the following procedure.

13. Install the right air crossover manifold to the engine intake manifold, connect the compressor air intake hose to the crossover manifold and to the compressor, and position the connection hose on the right and left crossover manifolds (Fig. 32).
14. Install the air crossover manifold attaching bolts, and tighten the two clamps on the compressor air intake hose.
15. Tighten the clamps on the connection hose.
16. Connect the air intake duct to the air crossover manifold and tighten the clamp.
17. Fill the cooling system, charge the reservoirs, and check for leaks.

GOVERNOR

Removal

The governor is mounted to the compressor with two attaching bolts. Mating ports in the governor and compressor bodies connect governor pressure to the unloading pistons in the compressor. Reservoir pressure is connected to the governor through a hose or tube.

1. Exhaust the air brake system.
2. On vertically-mounted units, disconnect the governor hose (end opposite governor) from the fitting in the reservoir pressure line. On side-mounted units, disconnect the pressure line at the governor.
3. Remove the two attaching bolts, then remove the governor.

Installation

1. On vertically-mounted units, transfer the hose to the replacement governor.
2. Install the governor and gasket and the two attaching bolts to the compressor. Apply sealer.
3. On vertically-mounted units, connect the hose to the fitting on the reservoir pressure line. On side-mounted units, connect the pressure line to the governor.
4. Test the governor as outlined in Diagnosis and Testing.

PRESSURE INDICATOR VALVE

The low pressure indicator valve is mounted at the passenger side of the dash panel (Fig. 34), and taps into a reservoir pressure line on the engine side of the panel.

Removal

1. Turn the ignition switch to the off position and exhaust the air from the brake system.
2. Disconnect the wire at the buzzer switch.
3. Disconnect the air line to the dash gauge and the line to the windshield wiper control. On some full air systems, also disconnect the lines to the tractor protection valve, to the manual emergency valve, and to the hand control valve (Fig. 34).
4. Unscrew the pressure indicator fitting at the engine side of the dash panel, and remove the assembly from the passenger side.

Installation

1. Mount the replacement unit to the passenger side of the dash panel and secure it to the panel by installing the pressure indicator fitting at the engine side.
2. Connect the wire to the buzzer switch, and connect the dash gauge and windshield wiper control lines. On some full air systems, connect the other lines as shown in Fig. 34.

AUTOMATIC MOISTURE EJECTOR VALVE

Removal

1. Block and hold the vehicle by other means than air brakes.
2. Drain the air system.
3. Remove the automatic moisture ejector valve from the reservoir drain port.

Installation

1. Install the moisture ejector valve in the reservoir drain port.
2. Build up air pressure in the reservoir before attempting to move the vehicle.

FOOT CONTROL VALVE

The brake valve has two tiers of four ports each (Fig. 25). The lower tier or ports connect to the reservoir pressure lines; the upper tier connects to the lines carrying brake service pressure. Of the four lower ports, one receives reservoir pressure; one sends reservoir pressure to the governor; and the other two (depending upon the model) either send reservoir pressure to some other part of the system, or they are plugged. On tractors, for example, the trailer emergency line connects to one of these ports in order to carry tractor reservoir pressure to the trailer reservoir.

One of the four upper ports sends valve delivery pressure to the stop light switch. Any or all of the three remaining ports (depending upon the model) can be used to deliver service pressure to the brake chambers or to the trailer. Any unused ports are plugged.

Removal

1. Open the reservoir drain cock(s) to exhaust the system.
2. Disconnect all but one line from the valve ports. Loosen, but do not disconnect, the remaining line. This line will prevent the valve from falling when the attaching bolts are removed.
3. Remvove the cotter key and pivot pin that connect the brake treadle to the control valve mounting plate.
4. Remove the three control valve attaching bolts (Fig. 35).
5. Disconnect the remaining air line from the control valve and remove the control valve.

Installation

1. If a replacement valve is being installed, transfer all brass fittings and the stop light switch to the replacement. Apply sealer to the threads before installation.
2. Remove the actuating button and the rubber seal from the control valve mounting plate to facilitate the positioning of the new valve (Fig. 35).
3. Position the new valve to the lower dash panel and mounting plate, then install three attaching bolts.
4. Install the actuating button in the mounting plate bore, then install the rubber seal to the button and mounting seal.
5. Assemble the brake treadle to the control valve mounting plate with the pivot pin and cotter key.
6. Connect the stop light wires (two nuts and flat washers), and connect the battery cable.
7. Connect the brake service line(s) to the upper ports in the valve.
8. Connect the compressor governor line and the reservoir pressure line(s) to the lower ports in the valve.
9. Start the engine to build up pressure. Check for leaks.

STOP LIGHT SWITCH

If the stop light does not operate, connect a jumper wire across the two switch terminals If the light now lights, replace the switch. If the light still does not light, repair or replace the two switch lead wires as necessary.

Removal

1. Disconnect the wires from the two terminals.

2. Turn the assembly out of the outlet port of the control valve.

Installation

Screw the new switch into the port, and connect the wires to the switch terminals.

QUICK RELEASE VALVE AND RELAY VALVE

The quick release valve is mounted as shown in Fig. 4. The relay valve is used on tandem models and is mounted as shown in Fig. 14. the following procedure applies to both valves with one exception. Before removing the relay valve, the system must be exhausted of air pressure. This is unnecessary when removing the quick release valve.

Removal

1. Disconnect the air lines at the valve.
2. Remove the mounting bolts and remove the valve.

Installation

1. Mount the valve in place and install and tighten the attaching bolts and nuts.
2. Inspect the exhaust port to be sure that it is not plugged.
3. Connect the air lines as shown in Fig. 4.

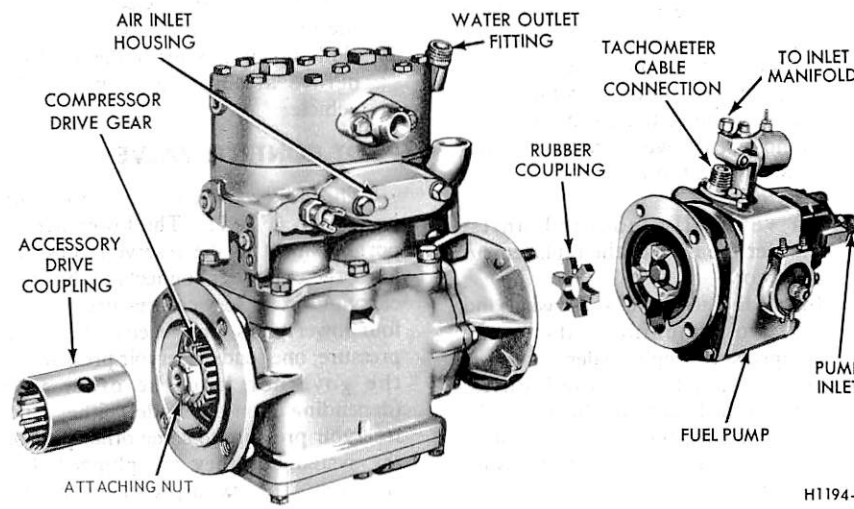

FIG. 31 Air Compressor and Fuel Pump Removed

OVERHAUL

Disassembly and overhaul of the automatic moisture ejector valve is the only major repair operation applicable to this section. If the compressor, reservoirs, governor, low pressure indicator and/or dash gauge do not operate properly, the component must be replaced.

AUTOMATIC MOISTURE EJECTOR VALVE

The automatic moisture ejector valve used in place of the reservoir drain cock on some models is to be disassembled and cleaned every fifty thousand miles or six months. The ejector valve must be removed from the air reservoir for cleaning.

Disassembly

Refer to Figure 3.

1. Remove the cap screws and lockwashers.
2. Remove the cover and sealing ring.
3. Remove the valve guide.
4. Remove the inlet and exhaust valve.
5. Remove the adapter and filter assembly.
6. Remove the filter retainer.
7. Remove the filter.
8. Wash metal parts in a good cleaning solvent. Rubber parts should be wiped clean.
9. Inspect all parts for wear or deterioration.
10. Clean and inspect filter and replace if clogged. **It is important that filter be in good condition. Do not put valve back into service without a clean filter.**
11. **Replace all parts not considered serviceable during these inspections.**

Assembly

1. Before assembling the valve, apply a light film of oil on inlet valve seat. **Do not apply oil to the inlet and exhaust valve.**
2. Place the sealing ring in groove of cover.
3. Place the valve guide over the inlet and exhaust valve.
4. Place the valve guide and inlet and exhaust assembly into the cover (wire will project through the exhaust port).
5. Place the body on the cover and install the cap screws and lockwashers.
6. Install the filter on the adapter and screw in the filter retainer.
7. Install the adapter and filter assembly in the body and tighten.

SPECIFICATIONS

S-CAM BRAKE ADJUSTMENT TABLE

Brake Chamber Type	Maximum Stroke at Which Brake Should Be Adjusted ①	Maximum Stroke After Adjustment ①
Front – Type no.9	1 3/8 inch	1.00 Inch
no.12	1 3/8 Inch	1.00 Inch
no.16	1 3/8 Inch	1.00 Inch
Rear – Type no.24	1 3/4 Inch	1 1/4 Inch

DESCRIPTION

Compressed air, admitted to the brake chamber by the foot control valve, enters the chamber behind a diaphragm which forces the push plate and push rod outward.

On the single wedge brake, one air chamber and actuator assembly, at one end of the shoes, forces the shoes against the drum (Figs. 1 and 2).

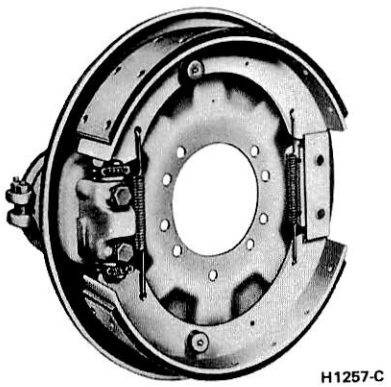

FIG. 1 Rockwell Single Wedge Brake

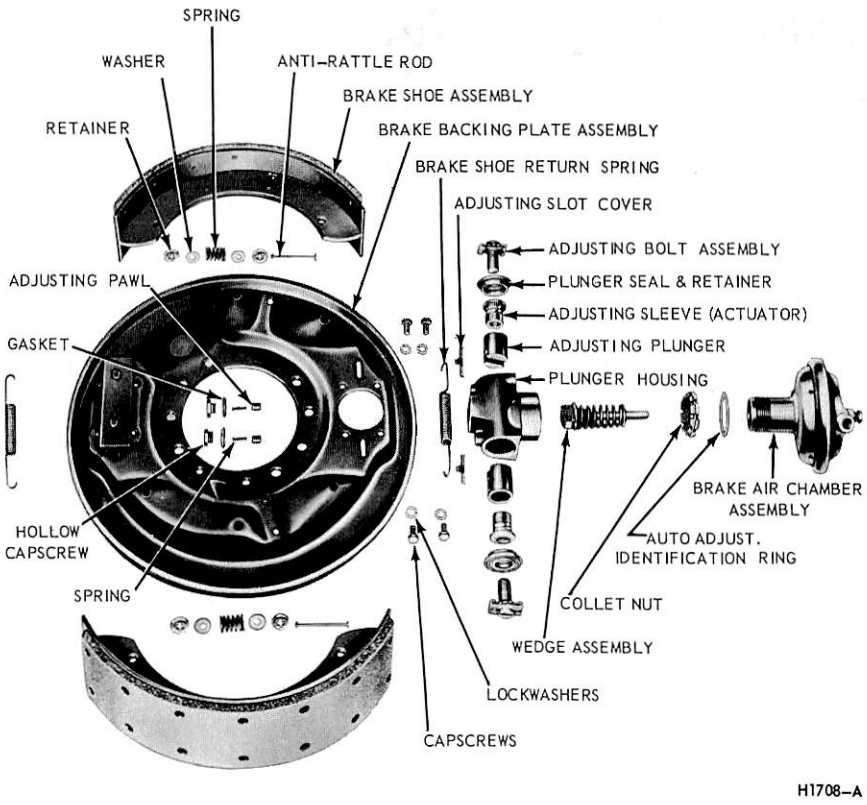

FIG. 2 Rockwell Single Wedge Brake—Disassembled

ADJUSTMENTS

WEDGE BRAKE

The wedge type air brakes are self adjusting. Instructions for servicing the automatic adapters are contained in Disassembly and Assembly.

A preliminary adjustment can be made by rotating the wheels forward and applying air to the brake chambers 25 or 30 times.

REMOVAL AND INSTALLATION

BRAKE SHOE

Removal

1. Remove the wheel, hub, and drum assembly.
2. Remove the brake shoe retracting springs (Figs. 1 and 2).
3. Remove the shoe hold-down springs (Fig. 1).
4. Remove the shoes.

Installation

1. Clean, inspect and lubricate the brake actuator and adjuster assemblies. Refer to Disassembly and Assembly.
2. Apply a film of high temperature grease at all shoe contact points.
3. Mount the ends of the brake shoes in the grooves in the actuating plungers. Install the shoe hold-down springs (Fig. 1).
4. Install **new** shoe retracting springs.
5. Install the wheel, hub, and drum assembly.

SERVICE AIR CHAMBER—ROCKWELL WEDGE TYPE BRAKE

Removal

Exhaust all air pressure from the system before attempting repair work.

1. Disconnect the air inlet line.
2. Using a drift and a light hammer, loosen the spanner nut.
3. Unscrew the service chamber assembly from the wedge housing.

Installation

1. Check position of the wedge in plunger housing to make certain wedge assembly is properly seated. Be sure to replace automatic adjusting identification ring on service chamber tube. Thread spanner nut onto power unit tube.
2. Screw the service chamber into the plunger housing until it bottoms (spanner nut loose).
3. Align connection ports with brake lines, if necessary, unscrewing service chamber not more than one full turn.
4. Connect brake lines.
5. Make and hold a full pressure brake application. Drive spanner nut with a drift and hammer until it is tight against the plunger housing. Release the brake pressure.
6. Check for leaks at all connections.

DISASSEMBLY AND ASSEMBLY

BRAKE SERVICE AIR CHAMBER

The following procedures are used to replace the diaphragm and boot with the non-pressure housing on the brake assembly.

Disassembly

1. Cage the power spring if the Fail-Safe unit is used.
2. Remove the air lines and tag the emergency line.
3. Remove the clamp ring nuts, bolt and the Fail-Safe warning tag and bottoming chamber tags if used.
4. Spread the clamp ring. Hold the diaphragm on the non-pressure half and remove the pressure half or Fail-Safe head.
5. Carefully remove the diaphragm while holding the diaphragm plate against the wedge rod. This will prevent the wedge assembly from coming out of engagement with the plungers.
6. Continue to hold the plate and inspect the boot. If the boot is torn or not attached to the housing, strip the old boot free from the housing and carefully remove the plate assembly off of the rod and out of the non-pressure housing tube. The boot and wedge guide will remain on the plate push rod.
7. Remove the wedge guide and old boot from the push rod. Inspect the guide for wear and replace if necessary.

Assembly

1. Install a new boot on the diaphragm plate push rod and press the wedge guide all the way onto the end of the push rod.
2. Clean the non-pressure housing with cement thinner or a similar material in the area where the boot is to be cemented.
3. Apply cement to the housing around the tube end. Position the plate-push rod assembly into the tube. Carefully engage the wedge rod so as to not pull it out of the plungers.
4. While holding the plate against the wedge, press the boot into position for cementing.
5. Install a new diaphragm over the plate and onto the non-pressure housing while pushing the plate against the wedge. Assemble the pressure half and clamp ring in the reverse manner of disassembly.
6. Connect the air lines to the proper chamber and Fail-Safe ports. Make a full-pressure brake application and check for air leaks. Road test for brake performance.

ACTUATING SYSTEM

Disassembly

1. Cage the power spring if Fail-Safe unit is used.
2. Remove the wheel hub and drum assembly, and the brake shoes.
3. Exhaust the air from the system and disconnect the air lines from the air chamber housing.
4. Remove the required brake service chambers from the actuator housings according to the procedure given in Removal and Installation.
5. Remove the guide screws and the gaskets from the plunger housing.
6. Remove the hollow cap screw, gasket, spring, and adjusting pawl (Fig. 3). Use a small magnet to remove the pawl.
7. Pry plunger seals loose and remove the anchor (solid) plungers, adjusting sleeves (actuator) and adjusting bolts.

Assembly

1. Thoroughly inspect and clean all parts, including the housing plunger and seal bores and shoe rest pads. **Do not solvent-clean any rubber parts (plunger seals or gaskets).** Wire brush plunger parts and adjusting bolt threads to remove any caked-on dirt and corrosion. Carefully inspect plunger seals and gaskets for tears, cuts, or deterioration, and replace if necessary. Also check the angled plunger roller faces for pits, grooves, or nicks and replace if necessary.

There is one adjusting plunger and one anchor (solid) plunger per plunger housing. The anchor plungers are marked on the shoe slot end. R for right

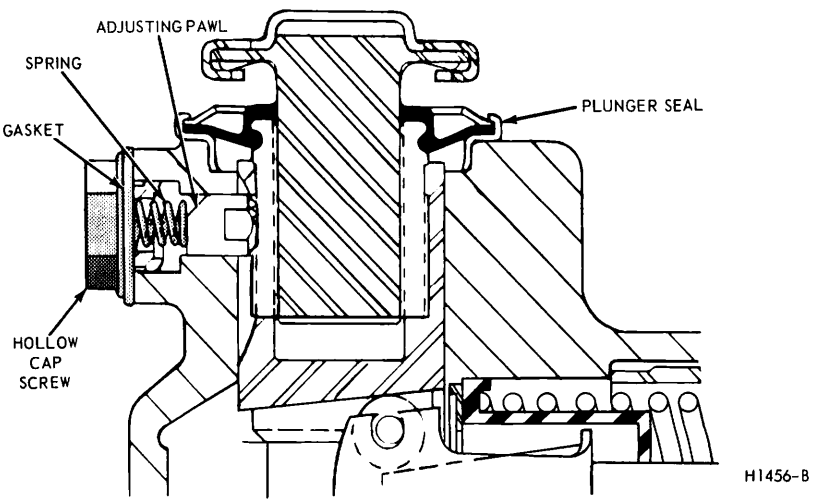

FIG. 3 Rockwell Adjuster—Sectional View

brakes and L for left. Do not mix at reassembly.

2. **Do not assemble the seals into the plunger housing first. This will result in complete lack of sealing of the internal plunger housing components.**
3. Apply a film of high temperature water proof lubricant (Rockwell Standard Part No. A-1779-W-283 or equivalent) to the inside surfaces of the seals.
4. On the anchor (solid) plungers, inspect the tapered nose for burrs. Mask the brake shoe web slot in the plunger nose with masking tape to protect the seal from the sharp edges of the slot (Fig. 4).
5. Carefully push the double lip seal onto the plunger, stretching the outer seal lip over the plunger nose end, until the inner seal lip is completely in the second plunger groove and the outer seal lip is in the first plunger groove (Fig. 5). Remove the masking tape.
6. Coat all plunger bores with high temperature waterproof lubricant (Rockwell-Standard Part No. A-1779-W-283 or equivalent).
7. **Anchor (solid) plungers. Make sure anchor plungers marked L are installed in left brake assemblies. Coat the entire plunger, and the packing cavity behind the seal with high temperature waterproof lubricant (Rockwell-Standard Part No. A-1779-W-283 or equivalent), and insert the plunger and seal into the housing with plunger key-way slot aligned with guide screw hole. Make certain the plunger goes all the way into the plunger bore and seats on the bosses at the bottom of the bore.**
8. Seat the plunger seal in the plunger housing using an appropriate seal driver or 1 3/4 inch socket (Fig. 6).
9. **Automatic Adjuster Plunger.** Lubricate the inside and outside surfaces of both the adjusting plunger and the adjusting actuator. Place the plunger into the plunger housing, aligning the plunger key-way slot with the guide hole.
10. Assemble the adjusting pawl into the plunger housing. **The adjusting pawl has flats on one end and a chamfered edge on the other end.** Coat the pawl with high temperature waterproof lubricant (Rockwell-Standard Part No. A-1779-W-283 or equivalent) and insert it into the guide hole, teeth first, with the chamfer toward the brake shoe. This aligns the pawl and actuator teeth and the flats with the key-way slot.
11. Insert the actuator into the plunger (Fig. 7) working the sleeve so that the pawl and sleeve teeth mesh. Push the actuator into the plunger until it bottoms.
12. Install the hollow cap screw with the spring and gasket.
13. Using the appropriate driver, seat the seal in the plunger housing (Fig. 6).
14. Check for proper meshing of the pawl and actuator teeth at this point, by lubricating the adjusting bolt threads and then threading the bolt into the adjusting sleeve. Thread the adjuster bolt into the actuator until it bottoms. A clicking sound and a ratcheting feel will indicate meshing of the teeth. Turn the bolt out three turns and if there is no clicking sound or ratcheting feel, mesh is correct. **Be careful, when inserting the bolt into the actuator, not to cut or damage the plunger seal.**
15. Tighten the hollow cap screw (Fig. 3) to 15-20 ft-lb.
16. Before installing the brake shoes, push the adjuster bolt and plunger into brake until seated, then turn the adjusting bolt into the actuator, just short of contacting the seal. **Do not bottom the adjusting bolt against the seal.**
17. Install the brake shoes.
18. Install the brake chambers in the housings per the instructions in Brake Chamber Installation.
19. Place the brake drum and hub over the shoes halfway. Adjust each show out an equal amount until there is 1/16 inch clearance at each shoe.
20. Install the wheels, hubs and drums.

		Removal and Installation	44-01
BRAKE SERVICE AIR CHAMBER		DESCRIPTION	44-01
Disassembly and Assembly	44-02		
Removal and Installation	44-01		

DESCRIPTION

Bendix wedge-operated air brakes are installed on certain models (Fig. 1). Shortstop air parking and safety brakes are available in conjunction with the system. Service instructions for the shortstop system are contained in the Parking Brake section of this manual.

Except where the Shortstop system is installed, two air service chambers are used on each rear brake assembly, and one service chamber on each front brake assembly.

ADJUSTMENTS

Wedge type brakes are self adjusting. Instructions for servicing the automatic adapters are contained in Disassembly and Assembly.

A preliminary adjustment can be made by rotating the wheels forward and applying air to the brake chambers 25 or 30 times.

REMOVAL AND INSTALLATION

BRAKE SHOE

Removal

All brake shoes, front and rear, are constructed with an adjusting end and an anchor end. When installing the shoes, make certain that the end with the thinner web is mounted correctly in the adjusting screw link. To remove the brake shoes, follow this procedure:

1. Remove the wheel and tire assembly and the hub and drum.
2. Unhook the two shoe-to-shoe springs (Fig. 1).
3. Remove the brake shoe hold-down springs and remove the shoes.

Installation

1. Coat the shoe slots in the shoe links with Lubriplate.
2. Clean the pads on the backing plate and coat the rubbing surfaces with the specified lubricant (Lubriplate).
3. Position the shoes on the backing plate with the thinner end of the shoe web in the adjusting screw link and the thicker end under the anchor block. Install the shoe-to-shoe springs (Fig. 1).
4. Clean the drum, as required, and install drum and hub, wheel and tire.
5. Apply the brakes several times before moving the truck, to assure proper seating and adjustment of the brake shoes.

SERVICE AIR CHAMBER

Removal

Exhaust all air pressure from the system before attempting repair work.

1. Disconnect the air inlet line.
2. Using a drift and a light hammer, loosen the lock nut.
3. Unscrew the service chamber assembly from the wedge housing.

Installation

1. Insert the service chamber assembly

into the wedge housing, making sure that the wedge shaft mates with the piston or diaphragm shaft seat.
2. Screw the service chamber assembly into the wedge housing until it bottoms, then back out less than one turn to align the unit with the air inlet line.
3. Screw the lock nut up against the lockwasher or casting, if a lockwasher is not used. Then, use a drift and hammer to tighten the lock nut an additional 1 1/2 teeth (3/16 turn).
4. Connect the air inlet line and store system air pressure. Check for operation.

DISASSEMBLY AND ASSEMBLY

ROTO CHAMBER—BRAKE SERVICE AIR CHAMBER—BENDIX WEDGE BRAKES

Disassembly
1. Remove the four hex head screws holding the cover to the body (Fig. 2).
2. Remove the cover, spring, boot and piston.
3. Remove the nut from the stud attaching the diaphragm clamp to the cover.
4. Work the diaphragm and diaphragm clamp out of the cover.
5. Straighten the rolled diaphragm (Fig. 2).
6. Clean all the metal parts in cleaning solvent. Inspect the body and cover for cracks or damage. Be sure the plunger is intact. Inspect the release spring and replace if cracked or damaged. Replace the boot at each overhaul.
7. Inspect the diaphragm for cracks. (Replace every 50,000 miles or 12 months, regardless of appearance).

Assembly
1. Coat the inside of the cover with a common oil soap.
2. Coat the diaphragm with a common oil soap and press it into the cup shaped diaphragm clamp. Roll the protruding edges of the diaphragm over the lip of the diaphragm clamp.
3. Insert the diaphragm and clamp assembly into the bore of the cover, working it in so that the diaphragm does not come off the lip of the diaphragm clamp.
4. Install the nut and washer on the diaphragm clamp stud and tighten securely.
5. Position the piston, boot and return spring. Then, install the chamber cover to the body with the four hex head attaching screws. Tighten securely.

MGM—BRAKE SERVICE AIR CHAMBER

Disassembly

Refer to Figure 3.
1. Remove the clamp ring fastening the cover to the body. Remove the cover and diaphragm.
2. If the boot is to be replaced, remove the piston and boot from the body.

Assembly
1. Clean the inside of the chamber. If a new boot is required it should be cemented to the chamber tube and allowed to dry at least five minutes or until tacky (3M No. EC-2141, or EC-1357 adhesive recommended).
2. Install the piston, making sure the wedge shaft fits into the piston seat. Also insure that the boot fits into the groove on the piston shaft.
3. Cement the new diaphragm to the piston and allow it to dry for at least five minutes or until tacky (3M No. EC-2141 or EC-1357 adhesive recommended).
4. Position the cover and install the clamp ring making sure the diaphragm is between the chamber body and the cover plate.
5. Tighten the clamp ring bolt and nut. Tap the circumference of the ring with a soft hammer to seat the ring and retighten the bolt and nut to 30-35 ft-lbs torque.
6. Soap test the clamp ring area for air leaks when air pressure is applied to the chamber.

ACTUATING SYSTEM

Disassembly
1. Remove the wheel hub and drum assembly, and the brake shoes.
2. Exhaust the air from the system and disconnect the air lines from the air chamber housing.
3. Remove the brake service chamber from the actuator housing according to the procedure given in Removal and Installation.
4. Pull out the wedge and return spring assembly. Use care to keep from damaging surfaces of wedges or rollers (Fig. 4).
5. Push in on the spring seat cup to compress the return spring (Fig. 4) and remove the retaining ring from the groove in the wedge shaft.
6. Disengage the dust boots from the actuator casting and then pull the plunger assemblies from the casting bore.
7. Remove the adjusting screw and nut assemblies from the adjuster plungers (Figs. 4, 5 and 6).
8. Disassemble screw, nut and dust boot and remove overload spring, link and detent spring.
9. Slide the automatic adjuster levers off the pins and remove the levers and springs.

Cleaning and Inspection
1. Clean the metal parts in a non-oily solvent. Replace the rubber parts whenever the brake is disassembled. Replace damaged or worn metal parts. Do not use gasoline or hot water solutions on metal parts.
2. Inspect the following parts as outlined and replace worn or damaged pieces:
   a. Check rod and wedge surfaces for scoring.
   b. Check outside surface of the plunger for scoring.
   c. Check the adjusting screws and nuts for sheared threads. Check adjuster ring teeth for wear.
   d. Check shoe web slot of the brake shoe links for roughness and cracks.
   e. Check the rollers for score marks and cracks.
   f. Check the spring clip for fatigue cracks.
   g. Check the adjuster levers for fatigue cracks and distortion.

Check for a broken adjuster lever spring.

h. Inspect the overload spring for fatigue cracks. Replace if test load is less than 13 lbs when spring ends are compressed 0.12 inch apart.

i. Inspect the adjuster plungers for scores and refinish with crocus cloth or hone.

j. Inspect the machined bores of the actuator casting for roughness. Use emery cloth to remove any rough areas which interfere with plunger movement. Check automatic adjuster pins for corrosion or distortion. Check the shoe pads on the backing plate for roughness on the rubbing surfaces.

Assembly

1. Coat all threads and bearing surfaces of links with Lubriplate. Use same lubricant on plunger and also dip spring and lever (Figs. 6 and 7) in light oil.
2. Assemble the adjusting screw nut through the adjuster tooth ring and align the slots as shown in Fig. 5.
3. Engage the overload spring securely. The ends of the spring must be in the hooks A and B (Fig. 5) of the nut and ring.
4. Check to be sure the parts are correctly installed by turning the ring clockwise in relation to the nut. The ring will move clockwise against the overload spring, when properly assembled, but must not be movable counterclockwise.
5. Install the detent spring on the link, aligning flats on each part and then press the link into the adjusting screw. Align the detent between starwheel teeth.
6. Install the dust boot on the adjusting screw from the threaded end. Coat the screw threads with lubricant and install the screw in the adjusting nut. **Turn the screw until it bottoms in the nut and then back out screw one full turn.**
7. Coat the inside diameter of the plunger bore with lubricant and install the screw and nut assemblies in the plunger.
8. Install the hook of lever return spring in the spring hole of the lever. Coat the lever and spring with light oil and install them in the cylinder casting by dropping the spring into its well and slipping the lever onto its pin (Fig. 7).
9. Coat the cylinder bore of the actuator with lubricant and install the plunger assembly in the bore, aligning the guide pin in the plunger with the slot in the casting.
10. Press the metal retainer portion of the dust boot into the cylinder housing until it bottoms against the shoulder of the casting.
11. Assemble the parts shown in Fig. 4 on the wedge shaft.
12. Compress the wedge return spring and install the retainer ring holding the parts in assembly.
13. Lubricate the wedge and rollers and install the wedge assembly into the actuator casting.
14. When installing the brake service chamber, make certain the end of the wedge shaft is seated in the piston assembly of the air chamber. Screw the air chamber into the wedge housing until the chamber bottoms, then back out less than one turn to align the chamber for line connections. Tighten the air chamber. See Service Air chamber Removal and Installation.
15. Assemble the shoes and shoe-to-shoe springs on the backing plate. A preliminary setting of the shoes can be made on the bench, using a 15 inch brake drum. To use a drum, set the wedge brake assembly in the drum and apply shop air several times to the air chamber. Each

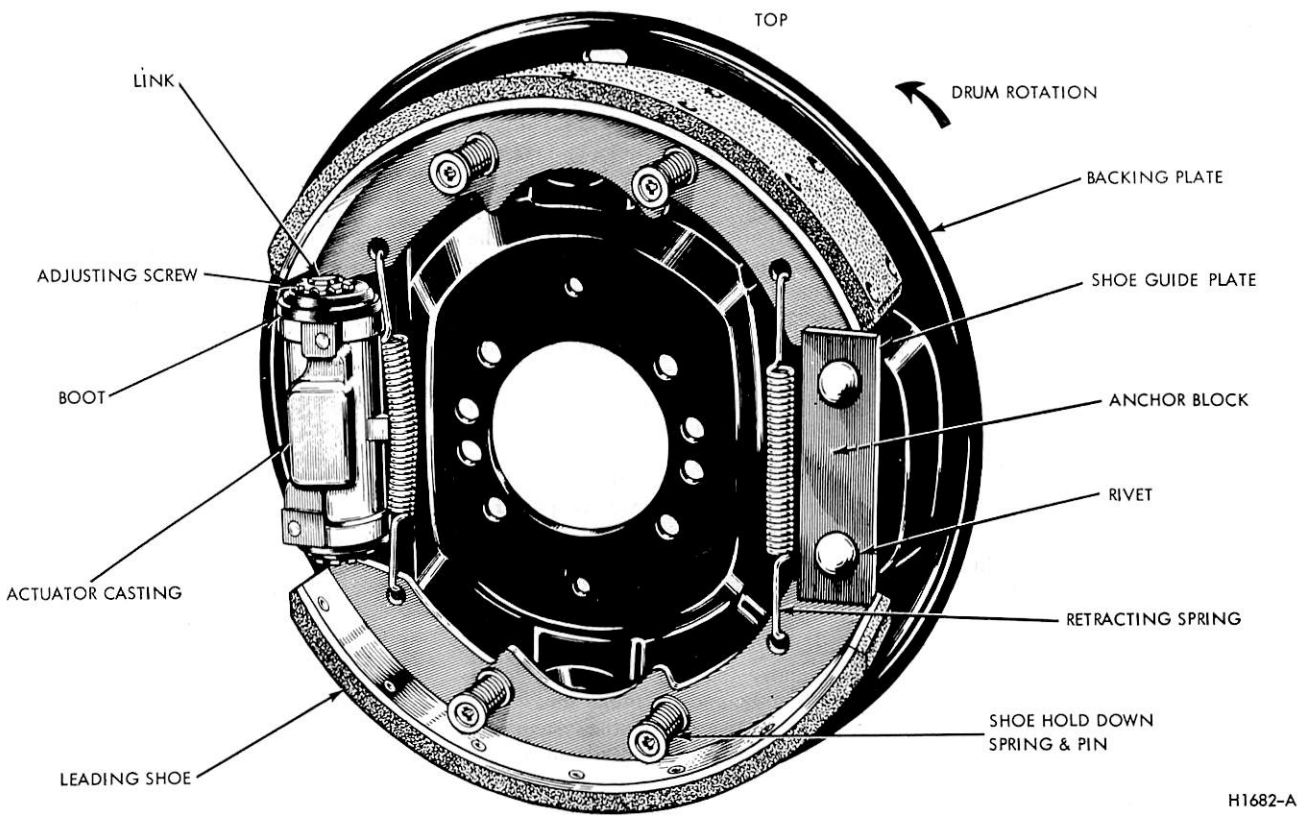

FIG. 1 Front Bendix Wedge Brake

automatic adjuster mechanism will maintain 0.040 inch clearance so assembly can be easily removed from the drum. After mounting the brake assembly to the truck, apply the brakes several times before moving the vehicle to assure proper seating of the brake shoes.

DESCRIPTION

Bendix wedge-operated air brakes are installed on certain models (Fig. 1). Shortstop air parking and safety brakes are available in conjunction with the system. Service instructions for the Shortstop system are contained in the Parking Brake section of this manual.

Except where the Shortstop system is installed, two air service chambers are used on each rear brake assembly, and one service chamber on each front brake assembly.

ADJUSTMENTS

Wedge type brakes are self adjusting. Instructions for servicing the automatic adapters are contained in Disassembly and Assembly.

A preliminary adjustment can be made by rotating the wheels forward and applying air to the brake chambers 25 or 30 times.

REMOVAL AND INSTALLATION

BRAKE SHOE

Removal

All brake shoes, front and rear, are constructed with an adjusting end and an anchor end. When installing the shoes, make certain that the end marked ADJ. END is mounted correctly in the adjusting plunger link. To remove the brake shoes, follow this procedure:

1. Remove the wheel and tire assembly and the hub and drum.
2. Unhook the two shoe-to-shoe springs (Fig. 1).
3. Remove the shoes.

Installation

1. Coat the shoe slots in the anchoring plunger inserts with Lubriplate.
2. Clean the shoe guide bosses and the steady rests on the torque spider and coat the rubbing surfaces with the specified lubricant (Lubriplate).
3. Position the shoes in the steady rests and install the shoe-to-shoe springs (Fig. 1). Be sure the end of the shoe marked ADJ. END is engaged in the link at the adjuster plunger (Fig. 1).
4. Clean the drum, as required, and install drum and hub, wheel and tire.
5. Apply the brakes several times before moving the truck, to assure proper seating and adjustment of the brake shoes.

SERVICE AIR CHAMBER

Removal

Exhaust all air pressure from the system before attempting repair work.

1. Disconnect the air inlet line.
2. Using a drift and a light hammer, loosen the lock nut.
3. Unscrew the service chamber assembly from the wedge housing.

Installation

1. Insert the service chamber assembly into the wedge housing, making sure that the wedge shaft mates with the piston or diaphragm shaft seat.
2. Screw the service chamber assembly into the wedge housing until it bottoms, then back out less than one turn to align the unit with the air inlet line.
3. Screw the lock nut up against the casting. Then, use a drift and hammer to tighten the lock nut an additional 1 1/2 teeth (3/16 turn).
4. Connect the air inlet line and store system air pressure. Check for operation.

DISASSEMBLY AND ASSEMBLY

ROTO CHAMBER—BRAKE SERVICE AIR CHAMBER

Disassembly

1. Remove the four hex head screws holding the cover to the body (Fig. 2).
2. Remove the cover, spring, boot and piston.
3. Remove the nut from the stud attaching the diaphragm clamp to the cover.
4. Work the diaphragm and diaphragm clamp out of the cover.
5. Straighten the rolled diaphragm (Fig. 2).
6. Clean all the metal parts in cleaning solvent. Inspect the body and cover for cracks or damage. Be sure the plunger is intact. Inspect the release spring and replace if cracked or damaged. Replace the boot at each overhaul.
7. Inspect the diaphragm for cracks. (Replace every 50,000 miles or 12 months, regardless of appearance).

Assembly

1. Coat the inside of the cover with a common oil soap.
2. Coat the diaphragm with a common oil soap and press it into the cup shaped diaphragm clamp. Roll the protruding edges of the diaphragm over the lip of the diaphragm clamp.
3. Insert the diaphragm and clamp assembly into the bore of the cover, working it in so that the diaphragm does not come off the lip of the diaphragm clamp.
4. Install the nut and washer on the diaphragm clamp stud and tighten securely.
5. Position the piston, boot and return spring. Then, install the chamber cover to the body with the four hex head attaching screws. Tighten securely.

MGM—BRAKE SERVICE AIR CHAMBER

Disassembly

Refer to Figure 3.

1. Remove the clamp ring fastening the cover to the body. Remove the cover and diaphragm.
2. If the boot is to be replaced, remove the piston and boot from the body.

Assembly

1. Clean the inside of the chamber. If a new boot is required it should be cemented to the chamber tube and allowed to dry at least five minutes or until tacky (3M No. EC-2141, or EC-1357 adhesive recommended).
2. Install the piston, making sure the wedge shaft fits into the piston seat. Also insure that the boot fits into the groove on the piston shaft.
3. Cement the new diaphragm to the piston and allow it to dry for at least five minutes or until tacky (3M No. EC-2141 or EC-1357 adhesive recommended).
4. Position the cover and install the clamp ring making sure the diaphragm is between the chamber body and the cover plate.
5. Tighten the clamp ring bolt and nut. Tap the circumference of the ring with a soft hammer to seat the ring and retighten the bolt and nut to 30-35 ft-lbs torque.
6. Soap test the clamp ring area for air leaks when air pressure is applied to the chamber.

ACTUATING SYSTEM

Disassembly

Refer to Figure 4 for disassembled view of brake component parts.

1. Remove the wheel hub and drum assembly, and the brake shoes.
2. Exhaust the air from the system and disconnect the air lines from the air chamber housing.
3. Remove the required brake service chambers from the actuator housings according to the procedure given in Removal and Installation.
4. Pull out the wedge and return spring assembly. Use care to keep from damaging surfaces of wedges or rollers (Figs. 4 and 5).
5. Push in on the spring seat cup to compress the return spring (Figs. 4 and 6) and remove the retaining ring from the groove in the wedge shaft.
6. Disengage the dust boot protectors and dust boots from the actuator casting and then pull the plunger assemblies from the casting bore.
7. Remove the adjusting screw and nut assembly from the adjuster plunger (Figs. 4 and 6).
8. Disassemble screw, nut and dust boot and remove overload spring, link and detent spring.
9. Slide the automatic adjuster lever off

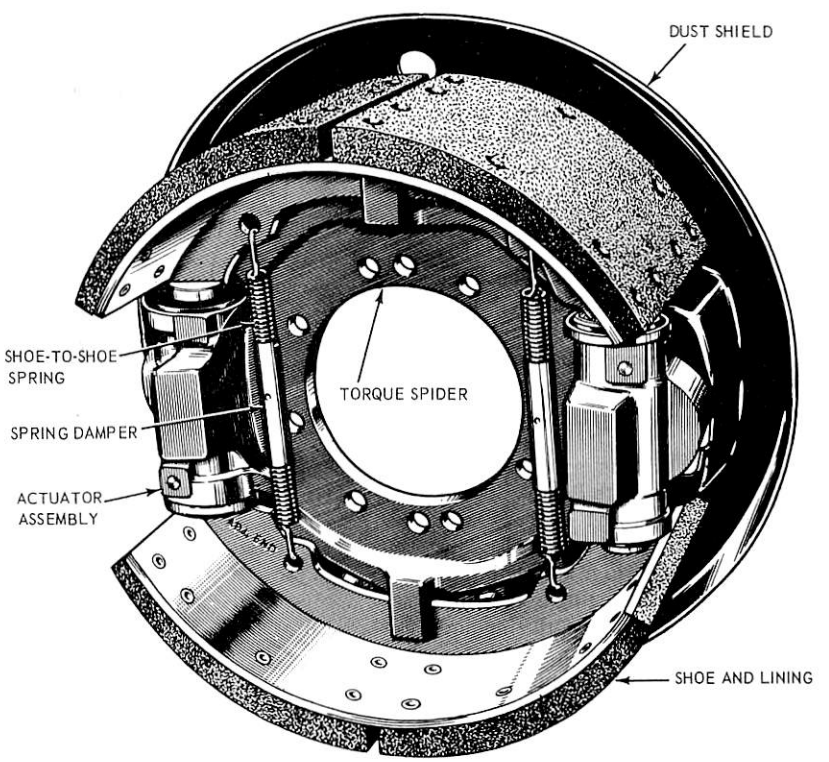

FIG. 1 Bendix Double Wedge Brake

the pin and remove the lever and spring.

Cleaning and Inspection

1. Clean the metal parts in a non-oily solvent. Replace the rubber parts whenever the brake is disassembled. Replace damaged or worn metal parts. Do not use gasoline or hot water solutions on metal parts.
2. Inspect the following parts as outlined and replace worn or damaged pieces:
   a. Check rod and wedge surfaces for scoring.
   b. Check outside surface of the plungers for scoring. On anchoring plunger inserts, check shoe web slot for roughness.
   c. Check the adjusting screws and nuts for sheared threads. Check adjuster ring teeth for wear.
   d. Check shoe web slot of the brake shoe link for roughness and cracks.
   e. Check the rollers for score marks and cracks.
   f. Check the spring clips for fatigue cracks.
   g. Check the adjuster levers for fatigue cracks and distortion. Check for a broken adjuster lever spring.
   h. Inspect the overload spring for fatigue cracks. Replace if test load is less than 13 lbs when spring ends are compressed 0.12 inch apart.
   i. Inspect the adjuster plunger for scores and refinish with crocus cloth or hone.
   j. Inspect the machined bores of the actuator casting for roughness. Use emery cloth to remove any rough areas which interfere with plunger movement. Check automatic adjuster pins for corrosion or distortion. Check the shoe guide bosses and steady rest for roughness on the rubbing surfaces. Inspect the mounting and holes of torque spider for cracks.

Assembly

1. Coat all threads and bearing surfaces of links with Bendix Special Brake Lubricant. Use same lubricant on plunger and also dip spring and lever (Fig. 7) in light oil.
2. Assemble the adjusting screw nut through the adjuster tooth ring and align the slots as shown in Fig. 6.
3. Engage the overload spring securely. The ends of the spring must be in the hooks A and B (Fig. 6) of the nut and ring.
4. Check to be sure the parts are correctly installed by turning the

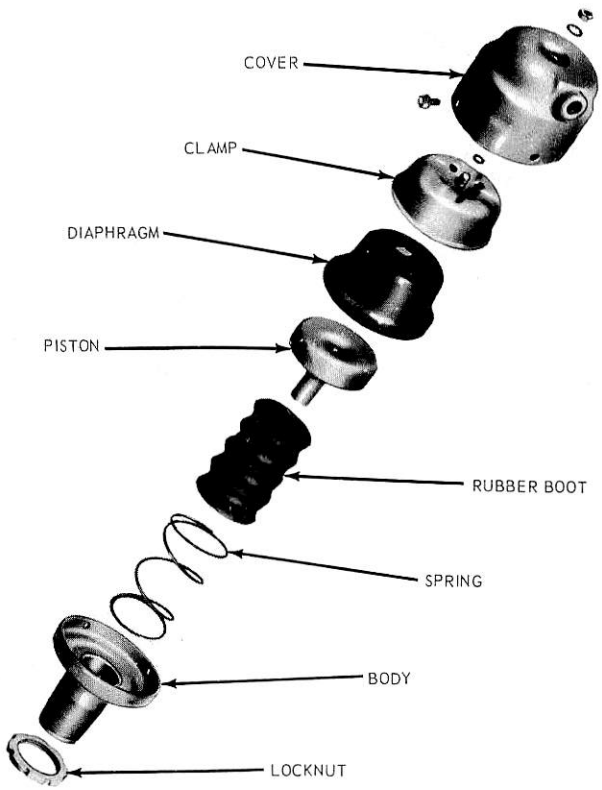

FIG. 2 Roto Chamber—Disassembled

ring clockwise in relation to the nut. The ring will move clockwise against the overload spring, when properly assembled, but must not be movable counterclockwise.

5. Install the detent spring on the link, aligning flats on each part and then press the link into the adjusting screw. Align the detent between starwheel teeth.
6. Install the dust boot on the adjusting screw from the threaded end. Coat the screw threads with lubricant and install the screw in the adjusting nut. **Turn the screw until it bottoms in the nut and then back out screw one full turn.**
7. Coat the inside diameter of the plunger bore with lubricant and install the screw and nut assemblies in the plunger.
8. Install the hook of lever return spring in the spring hole of the lever. Coat the lever and spring with light oil and install them in the cylinder casting by dropping the spring into its well and slipping the lever onto its pin (Fig. 8).
9. Coat the cylinder bore of the torque spider with lubricant and install the plunger assembly in the bore, aligning the guide pin in the plunger with the slot in the casting.
10. Press the metal retainer portion of the dust boot into the cylinder housing until it bottoms against the shoulder of the casting.
11. Assemble the parts shown in Fig. 4 on the wedge shaft.
12. Compress the wedge return spring and install the retainer ring holding the parts in assembly.
13. Lubricate the wedge and rollers and install the wedge assembly into the actuator casting.
14. Make certain that the anchoring plungers are assembled correctly, and that the new dust boots fit into the groove under the slotted end of the plunger inserts.
15. Install the plunger in the cylinder bore, making certain the guide pin in the side of the plunger is aligned in the cylinder slot.
16. With the plunger assembled in the cylinder bore, press the boot

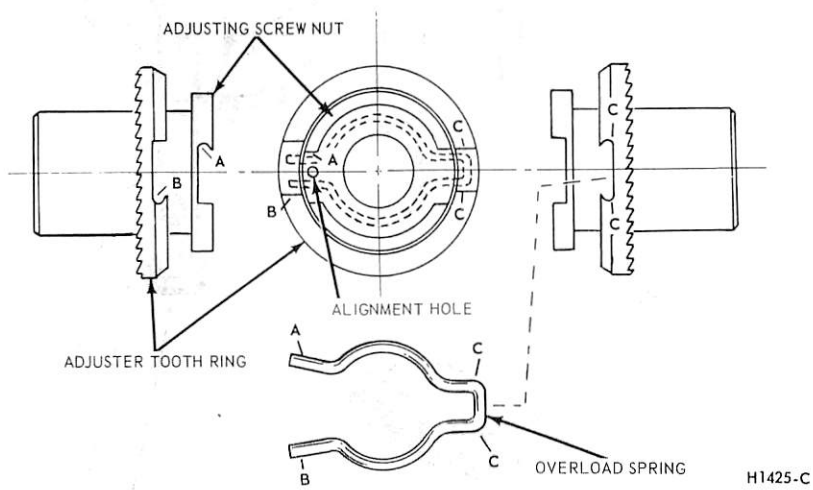

FIG. 6 Automatic Adjuster Details

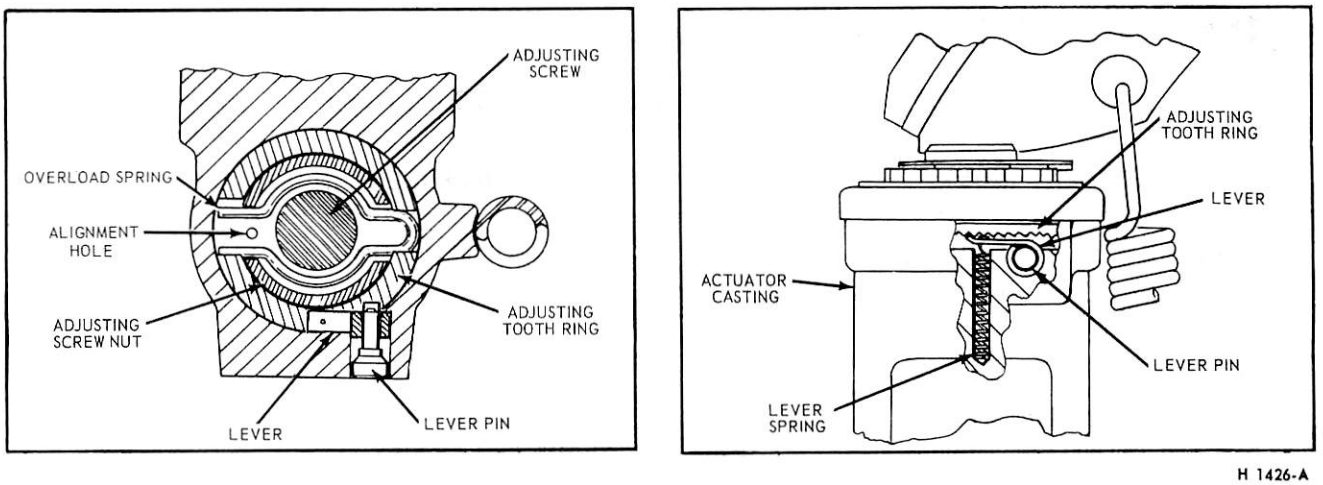

FIG. 7 Automatic Adjuster—Top and Side View

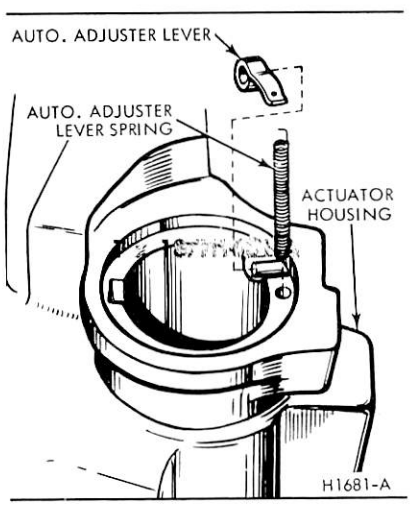

FIG. 8 Assembling Automatic Adjuster Lever and Spring

assembly retainer into the cylinder housing.

17. When installing the brake service chamber, make certain the end of the wedge shaft is seated in the piston assembly of the air chamber. Screw the air chamber into the wedge housing until the chamber bottoms, then back out less than one turn to align the chamber for line connections. Tighten the air chamber lock nut as shown in Removal and Installation.
18. Assemble the shoes and shoe-to-shoe springs to the torque spider. A preliminary setting of the shoes can be made on the bench, using a 15 inch brake drum. To use a drum, set the wedge brake assembly in the drum and apply shop air several times to the air chamber. Each automatic adjuster mechanism will maintain 0.040 inch clearance so assembly can be easily removed from the drum. After mounting the brake assembly to the truck, apply the brakes several times before moving the vehicle to assure proper seating of the brake shoes.

PART 12-48 Air Brakes—Cam Type

Applies To B, C, CT, F, L, LN, N, W, 600 Thru 9000 Series Trucks

COMPONENT INDEX	Page	COMPONENT INDEX	Page

DESCRIPTION

The cam-type brake is an air-operated two shoe brake. The front brake (Fig. 1) shoes each use a one piece shoe lining. The rear shoes each use a two piece lining (Fig. 3).

Air is applied to the brake chamber push rod which, in turn, causes a cam to rotate against rollers and forces the brake shoes outward against the brake drums.

ADJUSTMENTS

SLACK ADJUSTER ADJUSTMENT

Apply the brakes and measure the travel of the brake chamber push rod (Fig. 1). If equipped with a Maxi-brake unit, the minimum air pressure should be 90 psi while measuring the travel. The travel should be kept to the minimum possible without causing the brakes to drag. The maximum travel should not exceed the dimensions listed in the specifications. **Adjustment of the yoke on the brake chamber push rod should not be changed.** When new, the yoke is adjusted so that the slack adjuster brake chamber push rod angle is slightly greater than 90 degrees when the brakes are properly adjusted and the brakes are applied. Brake lining wear will not change this angle as long as the slack adjusters are kept adjusted to compensate for lining wear.

FRONT

This procedure applies only to trucks equipped with S-cam operated brakes.

A push rod travel, that reaches or exceeds the maximum listed in the Brake Chamber Push Rod Adjustment table in specifications (Part 12-40) indicates need of adjustment. Turn the adjusting screw clockwise until the push rod travels 3/4 inch in going from released to fully applied position (Fig. 1). When making the adjustment, turn the screw in quarter turns.

REAR

This procedure applies to vehicles equipped with either standard or Maxi-brake S-cam type slack adjusters.

A push rod travel, that reaches or exceeds the maximum listed in the Brake Chamber Push Rod Adjustment table in specifications indicates need of adjustment. Depress the lock sleeve and turn the hexagon head of the wormshaft clockwise until the push rod travels one inch in going from released to fully applied position (Fig. 2). Be sure that the lock sleeve comes back out and engages the hexagon head of the wormshaft so as to lock the adjustment.

When adjusting either front or rear slack adjusters, raise the wheels and make certain that there is no brake drag.

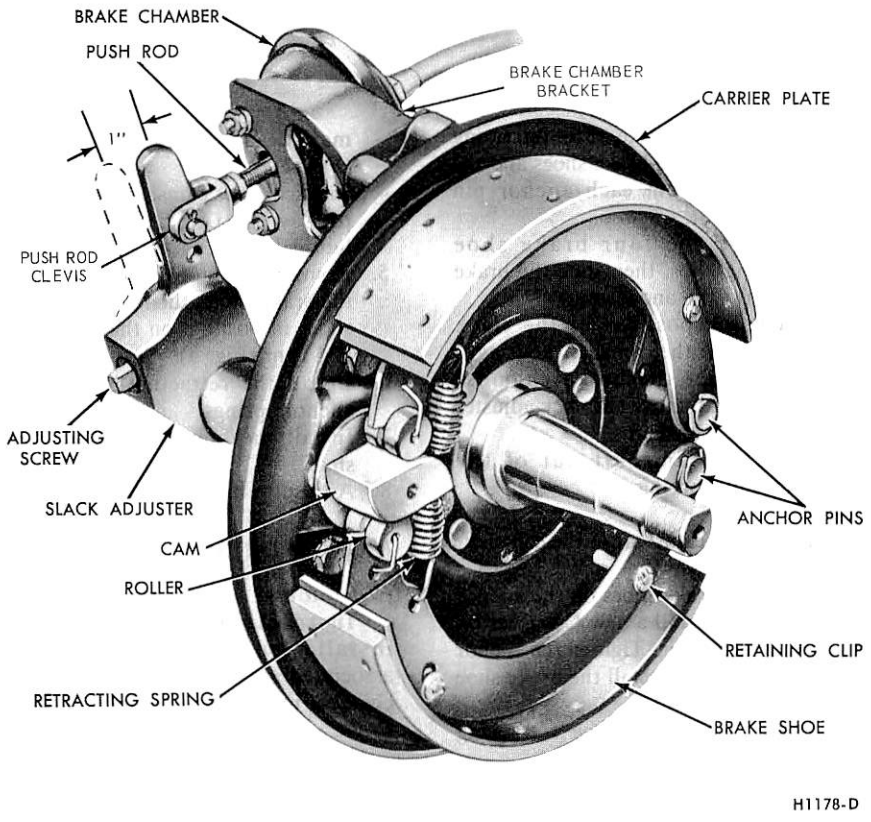

FIG. 1 Front Brake Assembly—S-Cam Type

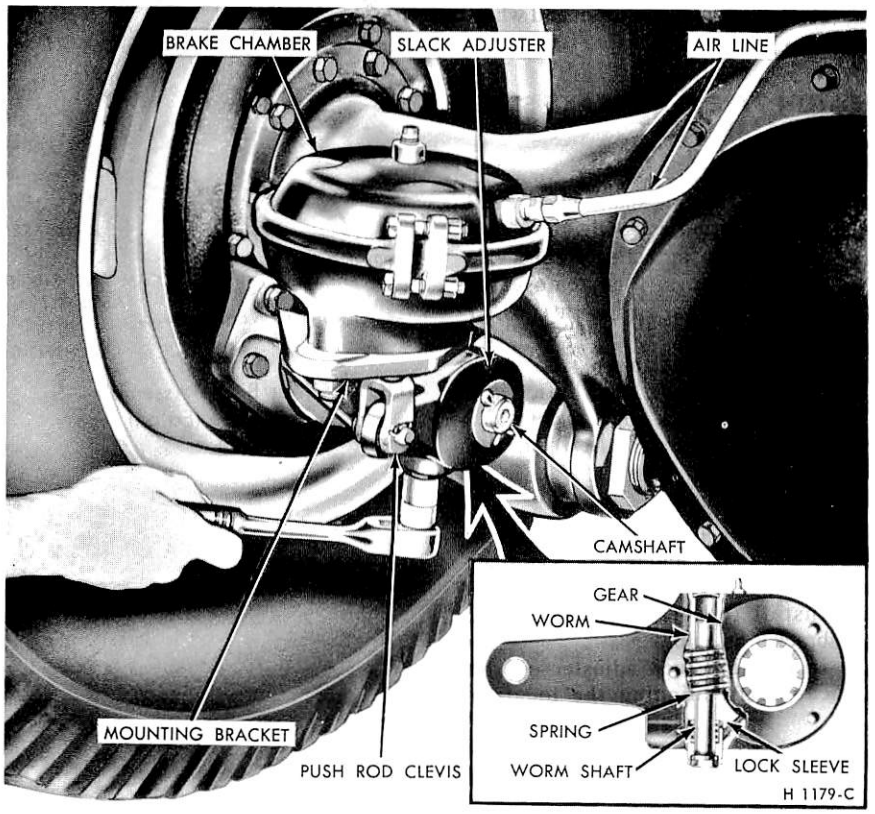

FIG. 2 Rear Brake Adjustment

REMOVAL AND INSTALLATION

BRAKE SERVICE AIR CHAMBER

Removal

1. Release all air from the system, then disconnect the air line at the brake chamber (Figs. 1 and 2).
2. Disconnect the push rod clevis from the slack adjuster.
3. Remove the attaching nuts and the brake chamber assembly.

Installation

1. If a replacement chamber is being installed, transfer the brake line fitting to the replacement brake chamber.
2. Position the brake chamber assembly on the mounting bracket and install the attaching nuts.
3. Install the clevis and cotter pin.
4. Connect the air line to the brake chamber.
5. Build up pressure in the system and inspect for leaks.
6. Adjust the brakes.

SLACK ADJUSTER

Removal

1. Remove the clevis pin attaching the slack adjuster to the brake chamber push rod (Figs. 1 and 2).
2. Remove the lock ring (front) or cotter pin (rear) attaching the slack adjuster to the camshaft.
3. Mark the position of the slack adjuster on the camshaft, then slide the slack adjuster off the shaft.

Installation

1. Place the slack adjuster on the camshaft, aligning the locating marks. Excessive front camshaft end play may be remedied by installing an additional spacer at the cam end of the camshaft. Install the lock ring (front) or the cotter pin (rear).
2. Connect the brake chamber push rod to the slack adjuster by installing the clevis pin in the upper hole, and install the cotter pin.
3. Lubricate the slack adjuster, and adjust the brakes.

FRONT BRAKE SHOE AND CAMSHAFT

Removal

1. Remove the wheel and hub and drum assembly.
2. Remove the brake shoe retracting spring from the brake shoes and the C-washer from each anchor pin (Fig. 1).
3. Remove the four brake shoe retaining clips, then slide the brake shoes off the anchor pin.
4. Mark the position of the slack adjuster on the camshaft housing.
5. Disconnect the brake chamber clevis, and remove the slack adjuster from the camshaft.
6. Pull the camshaft out of the camshaft housing.

Installation

1. Install the camshaft in the camshaft housing.
2. Slide the brake shoes on the anchor pins, and install a new C-washer on each anchor pin. Tighten the anchor pin lock nuts. Install the brake shoe hold down clips.
3. Install the brake shoe retracting spring.
4. Install the slack adjuster on the camshaft, lining up the marks. Install the camshaft snap ring.
5. Connect the brake chamber push rod clevis to the slack adjuster by installing the pin in the upper hole of the slack adjuster.
6. Install the hub and drum and wheel.

EATON TYPE REAR BRAKE SHOE AND CAMSHAFT

Removal

1. Remove the axle shaft, wheels, and hub and drum assembly.
2. Remove the retracting springs and anchor springs, then remove the brake shoes and cam roller assemblies (Fig. 3).
3. Mark the position of the slack adjuster on the camshaft, then remove the slack adjuster (Fig. 2).
4. Remove the camshaft from the backing plate.

Installation

1. Insert the camshaft through the backing plate and into the camshaft housing.
2. Install the brake chamber and bracket assembly.
3. Install the slack adjuster on the camshaft, aligning the locating marks, and install the cotter pin (Fig. 2).
4. Lubricate the camshaft, rollers, and pins with Lubriplate. Do not lubricate the cam face.
5. Position the cam rollers and pins in the brake shoes, then place the brake shoes in position on the anchor pin and cam (Fig. 3).
6. Install the retracting springs and anchor springs.
7. Install the hub, wheels, and axle shaft.
8. Adjust the brakes and slack adjuster.

MGM SHORTSTOP UNIT

Removal and Installation

Instructions for removal and installation of this unit and the associated service brake operating air chamber unit are covered in the Parking Brake section of this manual.

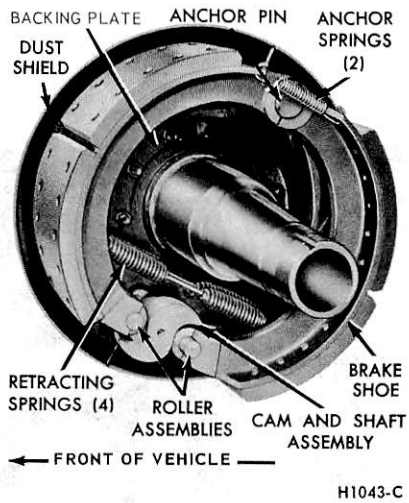

FIG. 3 Rear Brake Assembly—S-Cam Type (Eaton)

OVERHAUL

Major repair operation is applicable only to the brake chamber. If any of the components listed below are found to be worn or damaged they must be replaced.

Slack Adjuster
Front Camshaft
Rear Camshaft
Foot Control Valve
Stop Light Switch
Quick Release Valve
Relay Valve

SERVICE AIR CHAMBER

Disassembly

1. Before disassembling the brake chamber, mark both the non-pressure and pressure plates with relation to the clamping ring so that the bolts of the clamping ring can be placed at the same location during assembly. This will eliminate the possibility of installation interference when the brake chamber is installed on vehicle.
2. Pull the push rod outward against the spring so as to compress the spring and thus relieve the tension of the spring on the diaphragm and clamp ring (Fig. 4). Clamp the push rod in this position by using a vise or vise grip pliers on the rod at the non-pressure plate.
3. Remove the two clamp ring nuts and bolts. Spread the clamp ring slightly, and push the clamp ring off of the non-pressure plate half of the chamber and onto the pressure plate half.
4. Remove the pressure plate and diaphragm assembly from the non-pressure plate half of the chamber.
5. Remove the yoke and lock nut from the push rod. Release the vise clamp from the push rod. Remove the push rod assembly, return spring, seal, and seal spring from the non-pressure plate half of the chamber.

Assembly

Always be sure that the correct return spring is used in any brake chamber. Also be sure that the brake chamber on the opposite side of the axle has the same return spring; otherwise uneven braking will result.

If a new diaphragm is installed in the brake chamber on one side of the axle, a new one should be installed in the corresponding brake chamber on the opposite side also; otherwise uneven braking may result.

1. Rest the push rod assembly upright on a flat surface, then position in order the seal spring, push rod seal, return spring, and non-pressure plate over the push rod.
2. Force the non-pressure plate half of the chamber down against the spring until it rests on the flat surface. While holding the non-pressure plate against the tension of the return spring, clamp the push rod at the non-pressure plate with vise grip pliers or a similar tool (Fig. 4).
3. With the push rod held secure to the non-pressure plate, place the clamp ring over the clamping surface of the non-pressure plate, aligning the marks made before disassembly.
4. Position the diaphragm in the pressure plate half of the chamber and join with the open end of the non-pressure plate half, aligning the marks made during disassembly. While holding the two halves together, work the clamp ring over the clamping surface of the pressure plate half.
5. Using a vise grip pliers or similar tool, clamp one set of clamp ring lugs and draw them together. Assemble the bolt and nut in the other set of lugs and tighten. Remove the vise grip pliers and install the remaining bolt and nut. Tighten each clamp ring bolt and nut only enough to prevent leakage at the clamp ring surface.

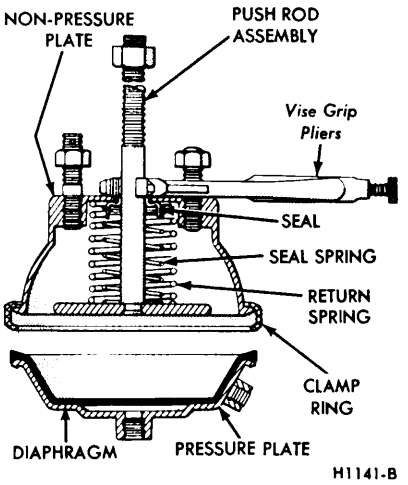

FIG. 4 Service Brake Chamber Assembly

PART 12-50 Vacuum Brake Booster—Single Diaphragm—Dash-Mounted (Bendix)

Applies to F-100—F-250 (6200 GVW)

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BOOSTER		PUSH ROD	
Removal and Installation	50-03	Adjustment	50-02
DESCRIPTION	50-01		

DESCRIPTION

Service information for only the vacuum boosters is given here. Adjustments and repairs for the hydraulic brake systems are given in Parts 12-01 and 12-02.

The single diaphragm type vacuum booster is a self-contained vacuum hydraulic power braking unit. It is of the vacuum-suspended type which utilizes engine intake manifold vacuum and atmospheric pressure for its power. It consists of three basic elements combined into a single unit as shown in Figs. 1 and 2.

The three basic elements are:

1. A vacuum power chamber which consists of a front and a rear shell, a diaphragm, a diaphragm plate, a hydraulic push rod and a vacuum diaphragm return spring.
2. A mechanically-actuated control valve, integral with the vacuum power diaphragm, which controls the degree of power brake application or release in accordance with the foot pressure applied to the valve operating rod through the brake pedal linkage.
3. A hydraulic dual master cylinder which supplies hydraulic pressure to the brake system.

The Bendix single diaphragm, dash-mounted booster is to be replaced as a unit. The vacuum check valve is the only component serviced on the booster assembly.

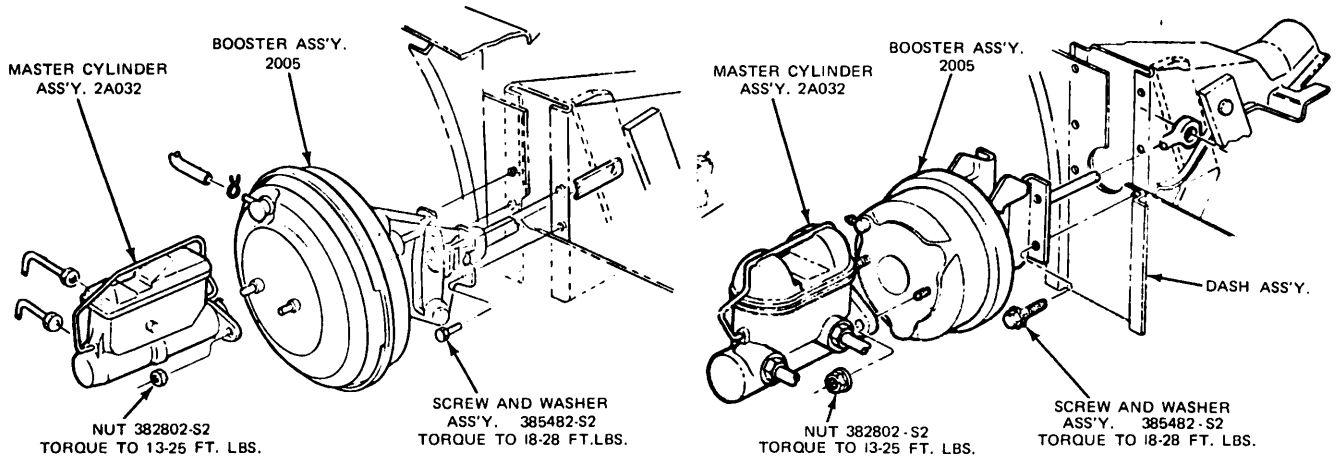

FIG. 1 F-100-250 (6200 G.V.W.) Vacuum Booster and Dual Master Cylinder

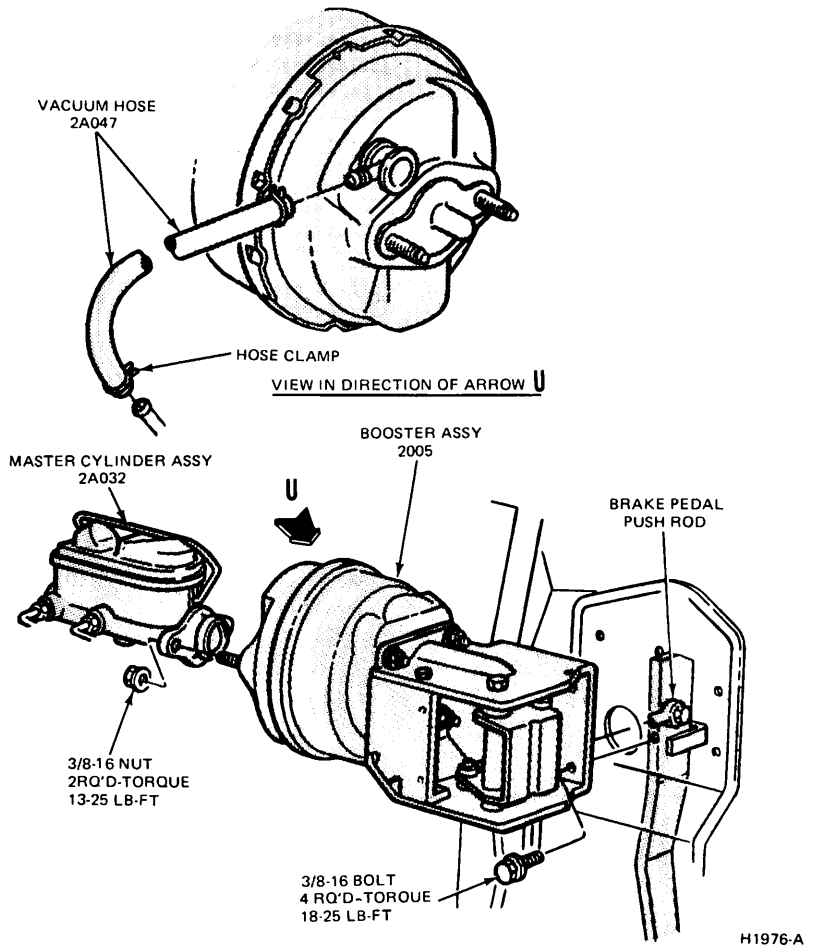

FIG. 2 Econoline Brake Booster Installation

ADJUSTMENTS

PUSH ROD ADJUSTMENT

The push rod is provided with an adjustment screw to maintain the correct relationship between the booster control valve plunger and the master cylinder piston. If the plunger is too long it will prevent the master cylinder piston from completely releasing hydraulic pressure and can cause the brakes to drag. If the plunger is too short it will result in excessive pedal travel and an undesirable clunk in the booster area. Remove the master cylinder for access to the booster push rod.

To check the adjustment of the screw, fabricate a gauge of the dimensions shown in Fig. 3. Then place the gauge against the master cylinder mounting surface of the booster body as shown in Fig. 3. The push rod screw should be adjusted so that the end of the screw just touches the inner edge of the slot in the gauge.

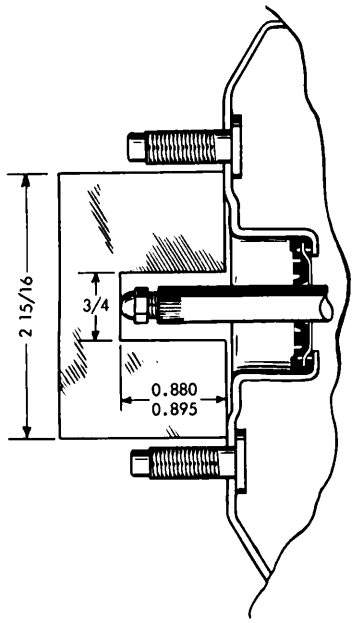

FIG. 3 Booster Push Rod Gauge Dimensions and Adjustment

REMOVAL AND INSTALLATION

BOOSTER

F-100-350

Removal

1. Support the master cylinder with a prop from the underside.
2. Remove the master cylinder-to-booster retaining nuts.
3. Loosen the clamp that secures the manifold vacuum hose to the booster, and then remove the hose.
4. Pull the master cylinder off the booster and leave it supported by the prop far enough away to allow removal of the booster assembly.
5. From inside the cab, remove the attaching bolt, nut and plastic bushings and disconnect the booster push rod from the brake pedal. Remove the nuts that retain the booster mounting bracket to the dash panel.
6. Remove the booster assembly from the engine compartment.

Installation

1. Mount the booster and bracket assembly to the engine side of the dash panel by sliding the bracket mounting bolts and valve operating rod in through the holes in the dash panel.
2. From inside the cab, install the booster mounting bracket-to-dash panel retaining nuts.
3. Position the master cylinder to the booster assembly, install the retaining nuts and remove the prop from underneath the master cylinder.
4. Connect the manifold vacuum hose to the booster and secure with the clamp.
5. From inside the cab connect the booster valve operating rod to the brake pedal with the attaching bolt, nut and plastic bushings.
6. Start the engine and check the operation of the brake system.

ECONOLINE

Removal

1. Disconnect the two hydraulic brake lines from the master cylinder.
2. Remove the cotter pin and clevis pin which secures the brake pedal push rod to the bellcrank.
3. Remove the four 3/8-16 bolts which secure the master cylinder and bracket assembly to the dash panel (Fig. 2).
4. Detach the vacuum hose from the brake booster and remove the booster and master cylinder assembly.
5. Remove the two 3/8-16 nuts which secure the master cylinder to the booster and remove the master cylinder.

Installation

1. Check and, if necessary, adjust the brake booster push rod (Fig. 3).
2. **Attach the master cylinder to the booster and torque the retaining nuts to 13-25 ft-lbs.**
3. Attach the vacuum hose to the brake booster.
4. **Position the master cylinder and booster assembly on the dash panel. Install the four retaining bolts and torque them to 18-25 ft-lbs.**
5. Attach the brake pedal push rod to the bellcrank. Insert and secure the cotter pin.
6. Connect the hydraulic brake tubes to the master cylinder. Torque the tube nuts to specifications. Bleed the hydraulic system as outlined in Part 12-01.

PART 12-52 Vacuum Brake Booster—Tandem Diaphragm—Dash-Mounted (Bendix)

Applies To F-350 With Disc Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BOOSTER		PUSH ROD	
Removal and Installation	52-02	Adjustment	52-01
DESCRIPTION	52-01		

DESCRIPTION

Service information for only the vacuum booster is given here. Adjustments and repairs for the hydraulic brake system is given in Parts 12-01 and 12-24.

The tandem diaphragm type vacuum booster, is a self-contained vacuum hydraulic power braking unit. It is of the vacuum suspended type which uses engine intake manifold vacuum and atmospheric pressure for its power. It consists of three basic elements combined into a single unit, as shown in Fig. 1.

These three basic elements are:

1. A vacuum power chamber which consists of a front and a rear shell, a center plate, a front and a rear diaphragm, a hydraulic push rod and a vacuum diaphragm return spring.
2. A mechanically actuated control valve, integral with the vacuum power diaphragms, controls the degree of power brake application or release in accordance with the foot pressure applied to the valve operating rod through the brake pedal linkage.
3. A hydraulic dual master cylinder which supplies hydraulic pressure to the brake system.

The Bendix tandem diaphragm, dash-mounted booster is to be replaced as a unit.

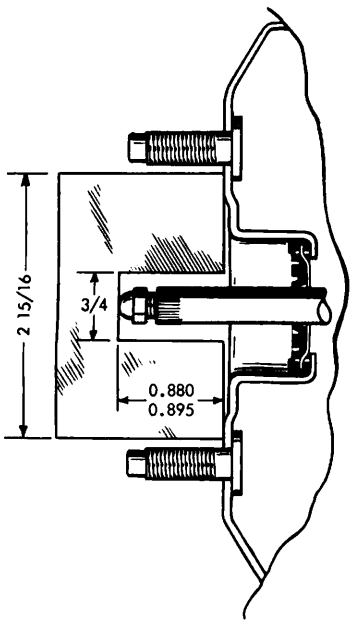
ADJUSTMENTS

PUSH ROD ADJUSTMENT

The push rod is provided with an adjustment screw to maintain the correct relationship between the booster control valve plunger and the master cylinder piston. If the plunger is too long it will prevent the master cylinder piston from completely releasing hydraulic pressure and can cause the brakes to drag. If the plunger is too short it will result in excessive pedal travel and an undesirable clunk in the booster area. Remove the master cylinder for access to the booster push rod.

To check the adjustment of the screw, fabricate a gauge of the dimensions shown in Fig. 2. Then place



H1330-D

FIG. 2 Bendix Booster Push Rod Gauge Dimensions and Adjustments

the gauge against the master cylinder mounting surface of the booster body as shown in Fig. 2. The push rod screw should be adjusted so that the end of the screw just touches the inner edge of the slot in the gauge.

REMOVAL AND INSTALLATION

BOOSTER

Removal

1. Support the master cylinder with a prop from the underside.
2. Remove the master cylinder-to-booster retaining nuts.
3. Loosen the clamp that secures the manifold vacuum hose to the booster, and then remove the hose.
4. Pull the master cylinder off the booster and leave it supported by the prop far enough away to allow removal of the booster assembly.
5. From inside the cab, remove the attaching bolt, nut and plastic bushings and disconnect the booster push rod from the brake pedal. Remove the nuts that retain the booster mounting bracket to the dash panel.
6. Remove the booster assembly from the engine compartment.

Installation

1. Mount the booster and bracket assembly to the engine side of the dash panel by sliding the bracket mounting bolts and valve operating rod in through the holes in the dash panel.
2. From inside the cab, install the booster mounting bracket-to-dash panel retaining nuts.
3. Position the master cylinder to the booster assembly, install the retaining nuts and remove the prop from underneath the master cylinder.
4. Connect the manifold vacuum hose to the booster and secure with the clamp.
5. From inside the cab connect the booster valve operating rod to the brake pedal with the attaching bolt, nut and plastic bushings.
6. Start the engine and check the operation of the brake system.

PART 12-53 Vacuum Brake Booster—Single Diaphragm, Frame-Mounted (Bendix)

Applies to 500–900 Series except P-500

COMPONENT INDEX	Page	COMPONENT INDEX	Page

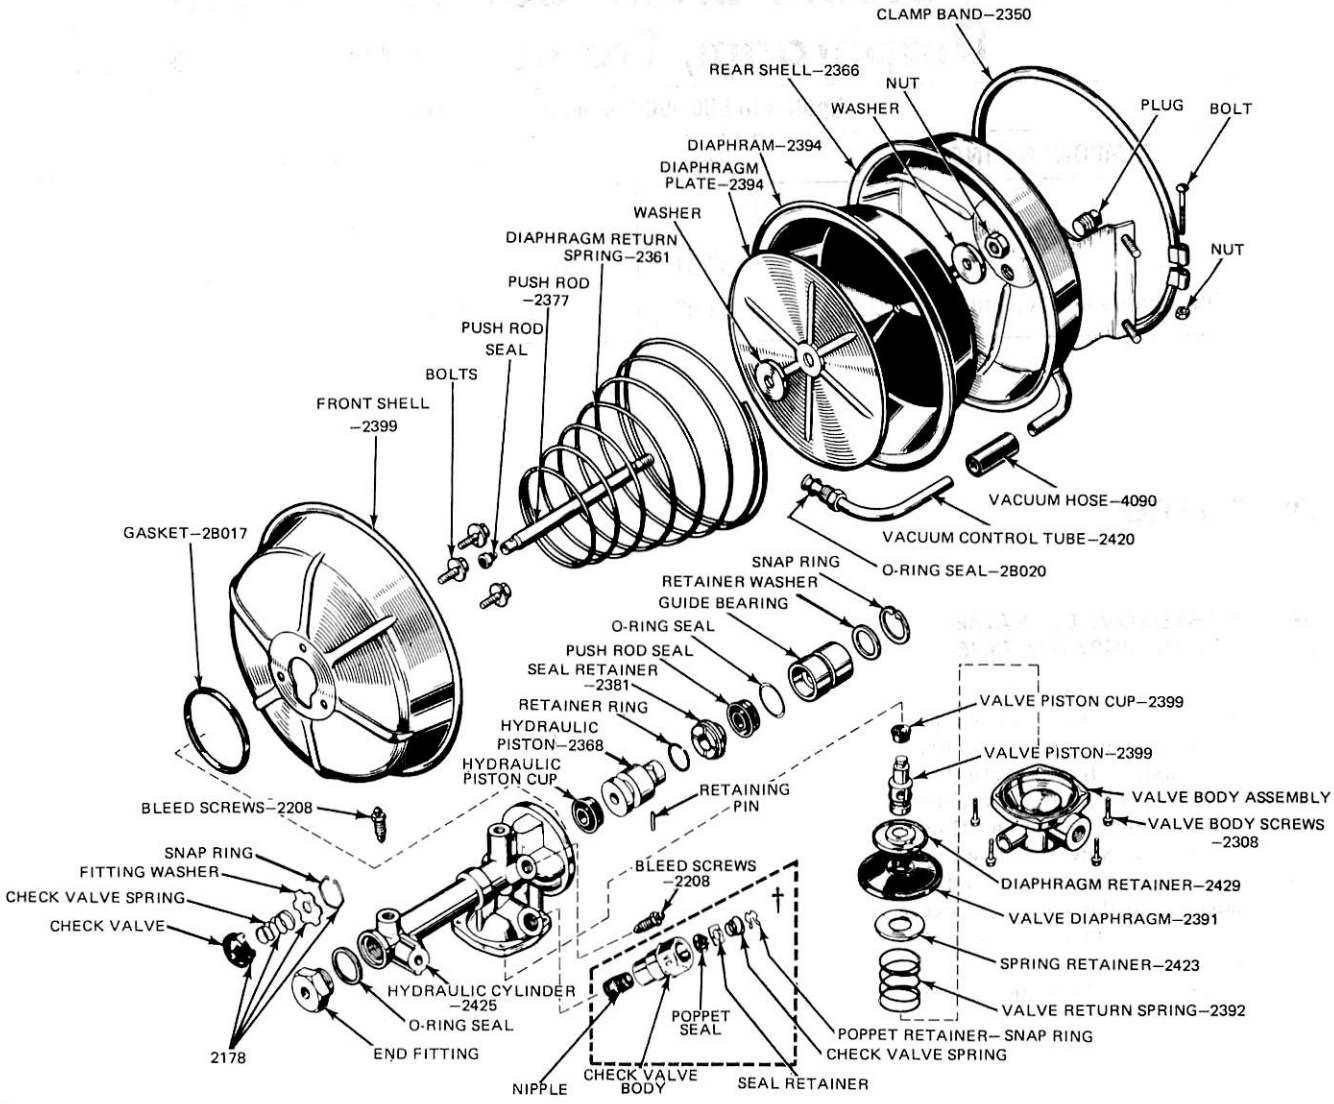
Disassembly and Assembly	53-03	Removal and Installation	53-02

DESCRIPTION

BENDIX (HYDROVAC) FRAME-MOUNTED DIAPHRAGM TYPE BOOSTER

The frame-mounted diaphragm type vacuum booster consists of a vacuum chamber, a hydraulically actuated vacuum control valve, and a hydraulic cylinder all in a single sealed unit (Fig. 1). A vacuum check valve, of the spring loaded disc type, is installed in the system adjacent to the vacuum source for maintaining maximum vacuum in the system.

Two booster assemblies are used on a split brake system.



† USED ON SPLIT SYSTEM INSTALLATION ONLY.

H1019-E

FIG. 1 Bendix Single Diaphragm, Frame-Mounted Booster — Disassembled

REMOVAL AND INSTALLATION

BENDIX DIAPHRAGM-TYPE FRAME-MOUNTED BOOSTER

Removal

1. Depress the brake pedal several times to remove all vacuum from the system.
2. Loosen the booster air inlet tube clamp, and remove the tube.
3. Disconnect the hydraulic lines and vacuum hose from the booster.
4. Remove the booster mounting bolts, and remove the booster from the bracket.

Installation

1. Position the booster on the mounting bracket. Then, install the mounting bolts using new lockwashers.
2. Connect the hydraulic lines. Tighten the connections securely.
3. Connect the air inlet tube to the booster. Tighten the hose clamp securely.
4. Bleed the brake system as outlined under Hydraulic System Bleeding, Part 12-01.
5. Connect the vacuum tube to booster hose to the booster. Tighten the hose clamps securely.
6. Perform the checks and tests as outlined in Part 12-01.

CONTROL VALVE

Removal and Installation

1. Clean all dirt from around the breather hose to air inlet tube connection and valve cover to booster mating surface.
2. Disconnect the breather hose from the air inlet tube and remove and discard the 4 valve body and cover attaching screws.
3. Discard the valve body and cover assembly, diaphragm, diaphragm plate, return spring and spring retainer.

4. Assemble a new diaphragm plate and diaphragm to the control valve piston. Make certain the inner bead of the diaphragm is seated in the groove of the control valve piston.
5. Install the spring retainer over the poppet seat end of the diaphragm seating against the diaphragm with the flange toward the valve body. Position the return spring between the spring retainer and the valve body assembly.
6. Seat the bead of the diaphragm in the groove around the valve cover flange and attach the cover to the slave cylinder with the four (4) cap screws tightened to 40-60 in-lbs.
7. Attach the breather hose to the air inlet tube. Inspect the entire length of this hose and replace it if any indication of leakage is noted.
8. Check booster operation.

OVERHAUL

BENDIX FRAME-MOUNTED DIAPHRAGM-TYPE BOOSTER

Disassembly

1. Scribe a mark across the front and rear shells and across the flange of the hydraulic cylinder. Disconnect the control tube nut from the control valve seat, and remove the seal from the tube.
2. Remove the nut and bolt from the clamp band. Disassemble the clamp band and the rear shell. **The plug should be removed from the rear shell only if the plug is damaged.**
3. Roll the bead of the diaphragm back from the flange of the front shell. Compress the diaphragm return spring slightly, and remove the snap ring from the groove near the end of the hydraulic cylinder bore. **Remove the hydraulic parts, push rod and diaphragm parts as an assembly.**
4. Slide the diaphragm return spring off the hydraulic piston end of the push rod. Remove the 3 bolts securing the hydraulic cylinder to the front shell, and remove the hydraulic cylinder and gasket from the front shell.
5. **The diaphragm assembly should be removed from the push rod only if necessary to replace damaged parts.**
6. Remove the retainer ring from the groove in the hydraulic piston, and press the pin from the hole in the piston and push rod. Remove the cup from the piston. If a new seal is to be installed in the end of the push rod, remove the old seal from the rod. **Be careful to avoid damaging the rod. Slide the seal retainer, seal, O-ring, guide bearing, retainer washer and snap ring from the push rod.**
7. Scribe a mark across the flanges of the valve body and housing. Remove the 4 screws, and then remove the valve body (Fig. 1). Remove the cups from the control valve piston.

Assembly

1. Install the check valve, spring, washer and snap ring in the hydraulic cylinder end fitting. Then assemble the O-ring seal and end fitting on the hydraulic cylinder.
2. Install the cups, back-to-back, on the control valve piston. Then assemble the piston, diaphragm retainer and valve diaphragm. **Be sure the inner bead of the diaphragm is seated in the piston groove.**
3. Install the spring retainer, flange down, on the spring in the valve body. Install the piston and diaphragm assembly on the retainer. Press the outer bead of diaphragm into the groove of the valve body.
4. Dip the control valve piston in clean heavy duty ESA-M6C25-A (C6AZ-10542-A) brake fluid, and assemble the piston in the control valve hydraulic cylinder bore. Align the scribe marks on valve body and housing, and attach with screws. Tighten screws to 40-60 in-lbs.
5. To install a new push rod seal in the push rod, place a new seal on a clean block of wood, rubber side down. With the push rod resting vertically on the seal stem, strike the threaded end of the push rod with a rawhide hammer to seat the seal stem in the push rod. **Be sure the shoulders of the push rod and seal are in contact.**
6. Slide the snap ring, retainer washer, guide bearing with O-ring seal in outer groove of guide bearing, seal cup and seal retainer on the push rod as shown in Fig. 1.
7. Attach the piston to the push rod with the retaining pin and retainer ring. Dip the cup in clean heavy duty ESA-M6C25-A (C6AZ-19542-A) brake fluid, and install the cup on the piston.
8. If the diaphragm, diaphragm plate and push rod were disassembled, assemble the nut, washer, diaphragm plate, diaphragm, washer and nut on the push rod. Install the nuts on the end of the push rod in two places.
9. Install the gasket in the groove on the flange end of the hydraulic cylinder. Align the cutout in the front shell with the port in the hydraulic cylinder, and install the cap screws. Tighten screws.
10. Install the diaphragm return spring, large coil first, against the diaphragm plate. Wet the hydraulic cylinder bore with the clean heavy duty ESA-M6C25-A (C6AZ-19542-A) brake fluid, and ease the hydraulic piston, cups and seals into the cylinder bore. Roll back the outer edge of the diaphragm, and press against the diaphragm to compress the return spring. Guide the parts on the push rod into the hydraulic cylinder bore, and install the snap ring in the cylinder bore. Be sure the snap ring is fully seated before releasing the pressure on the spring.
11. **Lightly coat both sides of the diaphragm bead with a silicone lubricant or talcum powder. Align the scribe marks on the front and rear shells, and press the rear shell flange and diaphragm bead into position against the front shell flange. Assemble the clamp band on the shells, and secure with bolt and nut. Tap the band lightly with a rawhide hammer while tightening the bolt and nut to specifications.**
12. Assemble a new seal on the control vacuum tube. Then assemble the tube and hose to the rear shell tube. Tighten the tube nut to specifications.
13. If removed, install the plug in the rear shell.

PART 12-54 Vacuum Brake Booster—Tandem Diaphragm—Frame Mounted (Bendix)

Applies to LT–LNT–LTS 800 and LT–LTS 900 With Single Brake System

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BOOSTER		Disassembly	54-02
		Removal and Installation	54-01
Assembly	54-03	CONTROL VALVE	
Cleaning and Inspection	54-03	Removal and Installation	54-01
		DESCRIPTION	54-01

DESCRIPTION

The tandem diaphragm (Hydrovac) (Fig. 1) is a self-contained hydraulic vacuum power brake unit actuated by the vehicle master cylinder pressure.

The tandem diaphragm Hydrovac consists of three functional components:

1. Two power chambers that contain separate power diaphragms that are connected by a push rod shaft extension to a single push rod, hydraulic cylinder.
2. A hydraulic cylinder that contains a hydraulic piston and cup assembly and a residual pressure check valve.
3. A vacuum control valve that is actuated by a control valve piston. The control valve piston in turn is actuated by pressure from the master cylinder.

REMOVAL AND INSTALLATION

BOOSTER ASSEMBLY

Removal

1. Depress the brake pedal several times to remove all vacuum from the system.
2. Loosen the booster air inlet tube clamp, and remove the tube.
3. Disconnect the hydraulic lines and vacuum hose from the booster.
4. Remove the booster mounting bolts, and remove the booster from the bracket.

Installation

1. Position the booster on the mounting bracket. Then, install the mounting bolts using new lockwashers.
2. Connect the hydraulic lines. Tighten the connections securely.
3. Connect the air inlet tube to the booster. Tighten the hose clamp securely.
4. Bleed the brake system as outlined under Hydraulic System Bleeding, Part 12-01.
5. Connect the vacuum tube to booster hose to the booster. Tighten the hose clamps securely.
6. Perform the checks and tests as outlined in Part 12-01.

CONTROL VALVE

Removal and Installation

1. Clean all dirt from around the breather hose to air inlet tube connection and valve cover to booster mating surface.
2. Disconnect the breather hose from the air inlet tube and remove and discard the 4 valve body and cover attaching screws.
3. Discard the valve body and cover assembly, diaphragm, diaphragm plate, return spring and spring retainer.
4. Assemble a new diaphragm plate and diaphragm to the control valve piston. Make certain the inner bead of the diaphragm is seated in the groove of the control valve piston.
5. Install the spring retainer over the poppet seat end of the diaphragm seating against the diaphragm with the flange toward the valve body. Position the return spring between the spring retainer and the valve body assembly.
6. Seat the bead of the diaphragm in the groove around the valve cover flange and attach the cover to the slave cylinder with the four (4) cap screws tightened to 40-60 in-lbs.
7. Attach the breather hose to the air inlet tube. Inspect the entire length of this hose and replace it if any indication of leakage is noted.
8. Check booster operation.

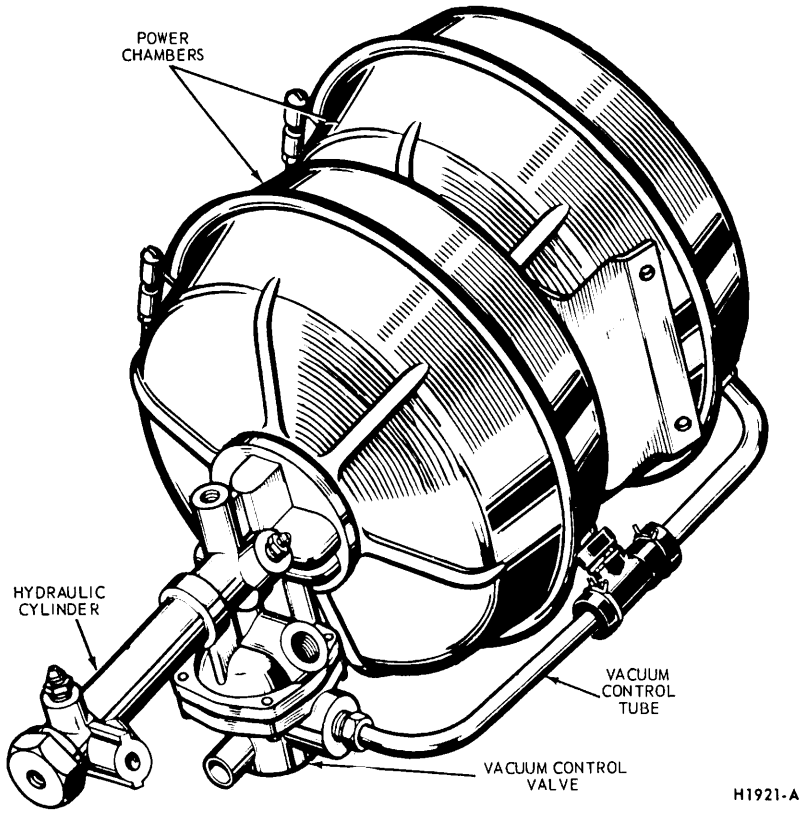


FIG. 1 Bendix Tandem Diaphragm — Frame-Mounted Vacuum Booster

OVERHAUL

The following service procedures cover disassembling, cleaning, inspecting and assembling the tandem diaphragm Hydrovac. Always be careful when handling hydraulic parts to avoid getting mineral oil or grease on the parts. Do not handle rubber cups or seals with greasy hands.

When overhauling a unit, always use the correct repair kit for that unit. Plug all open ports and clean the dirt from the outside of the unit with a mild soap or a detergent solution. Then, remove the plugs and apply clean, dry air pressure to the hydraulic input port on top of the hydraulic cylinder to blow brake fluid out of the unit.

Disassembly

Refer to Figure 2.

1. Scribe a mark across both clamping rings onto the shell surfaces beside each ring. Scribe across the top surface of the hydraulic cylinder flange and onto the front shell. Also scribe across the flanges of the control valve body and control valve housing below the hydraulic cylinder.
2. Disconnect the control tube and nut from the control valve port. Remove the three hose clamps and the hose tee. Remove the ring seal from the control tube.
3. Remove the nut, screw and rear clamping ring; then remove the rear shell (Fig. 3).
4. Remove the nut, screw and front clamping ring. Then separate the front, center and rear shells and remove the diaphragm assemblies.
5. Clamp the hydraulic cylinder in a vise equipped with soft-jawed inserts. Be careful to avoid damage to the cylinder.
6. Press on the spring retainer to compress the diaphragm return spring and remove the three bolts that secure and support plate and front shell to the hydraulic cylinder (Fig. 4). Slowly release pressure on the return spring and pull the push rod and hydraulic piston from the hydraulic cylinder.
7. Slide the return spring off the hydraulic piston end of the push rod. Do not remove the spring retainer from the other end of the push rod except to replace damaged parts.
8. Remove the snap ring from its groove in the hydraulic piston and press the valve plunger pin from the hole in the piston and push rod (Fig. 5).
9. Slide the hydraulic piston, snap ring, seal retainer (piston stop), push rod cup, push rod bearing and support plate and piston stop assembly from the push rod.
10. Remove the cup from the hydraulic piston and O-ring from its groove in the push rod bearing.
11. Remove the end fitting from the hydraulic cylinder. Use needlenose pliers to remove the snap ring from the end cap and disassemble the residual pressure check valve parts.
12. Remove the end fitting seal from the push rod. **Be careful not to scratch the push rod.**
13. Clamp the nut on the push rod seat end of the rear shaft in a vise and remove the nut by unscrewing the shaft with a drift punch through the holes in the shaft which are close to

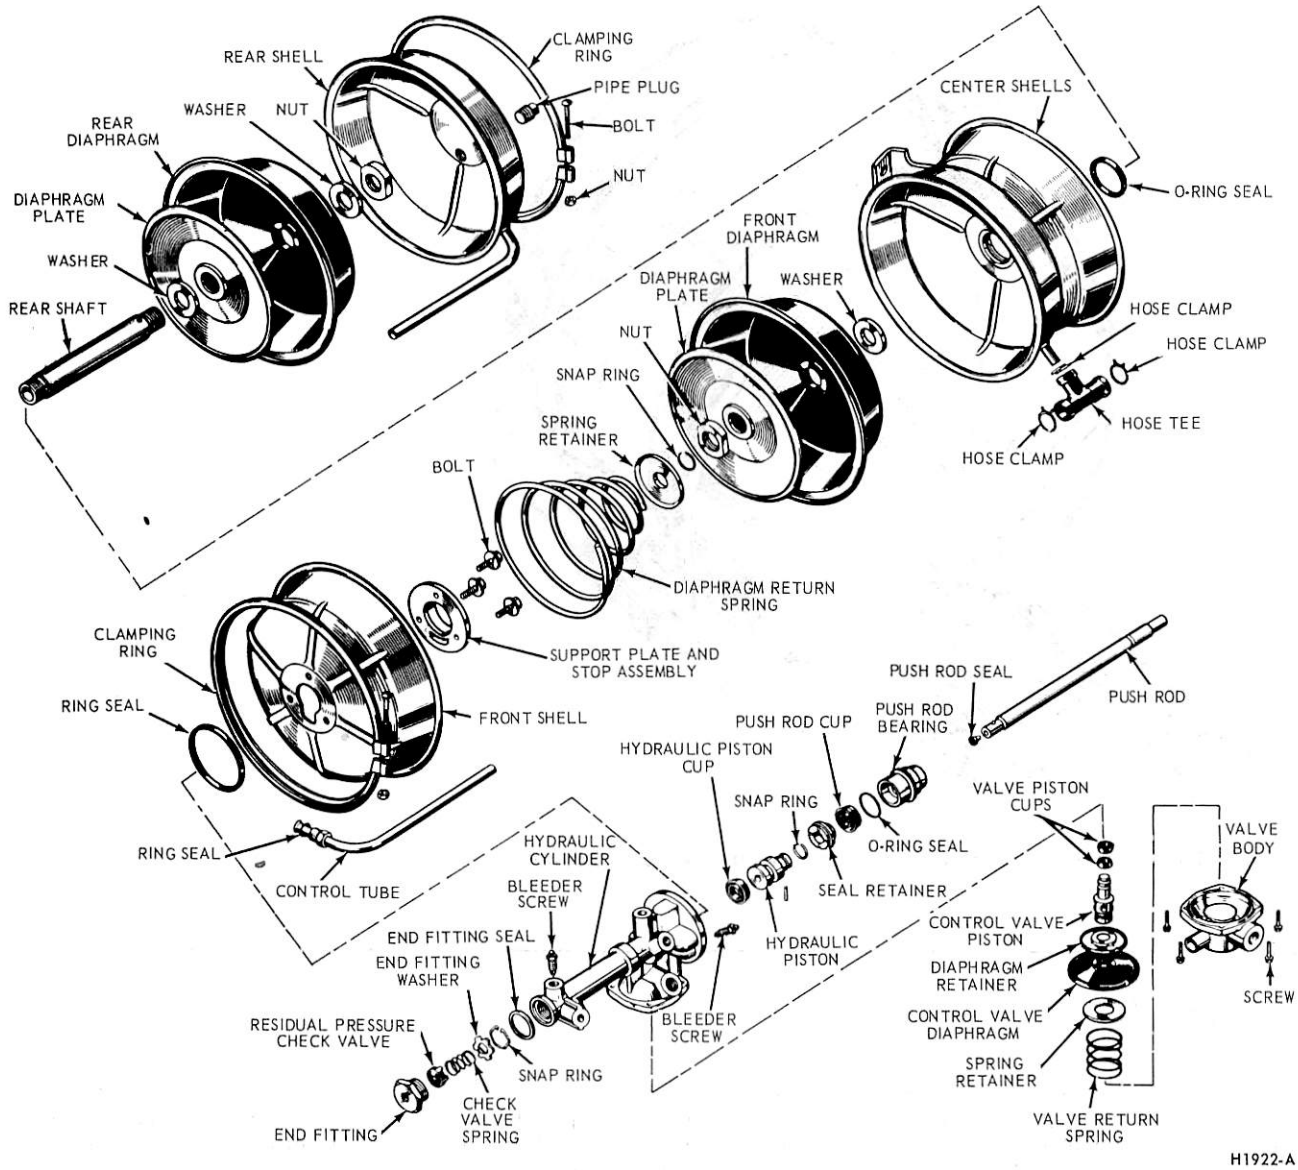

FIG. 2 Bendix Tandem Diaphragm — Frame-Mounted Vacuum Booster — Disassembled

the rear diaphragm (Fig. 6). Remove the assembly from the vise and then remove the front diaphragm and diaphragm plate from the shaft.

14. Slide the center shells off the shaft. Use an ice pick or probe to remove the O-ring seal from its groove in the hub of the center shells.
15. Clamp the nut on the rear end of the shaft in a vise and loosen the shaft with a drift punch as in Step 13. Remove the nut, washer, rear diaphragm, diaphragm plate and washer from the shaft.
16. Remove the screws, valve body and control valve parts from the valve housing (Fig. 7).
17. Remove the cups from the control valve piston. Slide the control valve diaphragm and diaphragm retainer off the opposite end of the piston.

Cleaning and Inspection

Thoroughly clean all metal parts in a metal parts cleaner. Discard all old parts which are to be replaced with new parts.

Rinse all metal hydraulic parts in clean isopropyl alcohol. Clean plastic parts and any rubber parts to be re-used in clean isopropyl alcohol.

Inspect the diaphragms for kinks, cracks or tears and replace any questionable diaphragms. Inspect all metal and plastic parts for burrs, nicks, cracks or scores and remove them with crocus cloth or replace the damaged part.

Inspect the shells for dents, cracks or broken welds. Do not attempt to disassemble the center shell assembly. Inspect the hydraulic cylinder bore and control valve bore for surface damage. Polish with crocus cloth to remove deposits, light score marks or pitted areas. Replace part if damage cannot be removed with crocus cloth.

Blow out all ports with clean, dry shop air to remove metal parts cleaner and dirt. Rinse bores and passages with clean isopropyl alcohol or brake fluid.

Assembly

1. Assemble the valve piston cups back-to-back in grooves of the control valve piston (Fig. 7).
2. Slide the diaphragm retainer, flange side first, onto the other end of the control valve piston. Wet the I.D. of the diaphragm in alcohol and slide it over the end of the piston and seat it against the retainer. Assemble the spring retainer onto the hub of the diaphragm with the flange side away from the diaphragm.

3. Assemble the control valve piston and diaphragm assembly on the valve return spring. Position the spring in the valve body around the vacuum poppet guides and press the diaphragm bead firmly into the groove on the flange of the valve body.
4. Dip the control valve piston and cups in clean brake fluid and insert them in the control valve bore of the hydraulic cylinder. Align the scribe marks on the flanges of the valve body and housing and attach the body to the housing with four screws. Tighten the screws to 40-60 in-lbs.
5. Assemble the washer, rear diaphragm plate, rear diaphragm and washer as shown in Fig. 6 on the end of the shaft close to the holes in the shaft.
6. Install the nut on the end of the shaft and grip the nut in a vise. Use a drift through the shaft holes to tighten the nut to 10-15 ft-lbs. Stake the nut in two places.
7. Assemble the O-ring seal in its groove inside the hub of the center shells. Coat the seal and bearing surface with a silicon lubricant. Coat the outer surface of the rear shaft with a silicone lubricant.
8. Insert the end of the rear shaft, from side shown, through the bearing hub and seal of the center shells.
9. Assemble the washer, front diaphragm, and diaphragm plate on the end of the shaft. Screw the nut on the shaft and tighten the nut to 10-15 ft-lbs. Stake the nut in two places.
10. To assemble a new push rod seal (Fig. 5) in end of the push rod, place the new seal on a clean block of wood, rubber face down. With the push rod resting vertically on the seal stem, strike the end of the push rod with a rawhide hammer to seat the seal. Be sure that the shoulders of the seal and rod are in contact.
11. Wet the push rod, push rod bearing and all hydraulic parts in clean brake fluid. Slide the support plate and piston stop assembly, push rod bearing, with O-ring seal installed in its groove, push rod cup, and seal retainer on the push rod as shown.
12. Position the snap ring on the piston but **not** in its groove. Attach the piston to the end of the push rod with the valve plunder pin. Then, slide the snap ring into its groove in the piston to cover the plunger pin holes.
13. Dip the hydraulic piston cup in clean brake fluid and assemble it on the piston as shown.

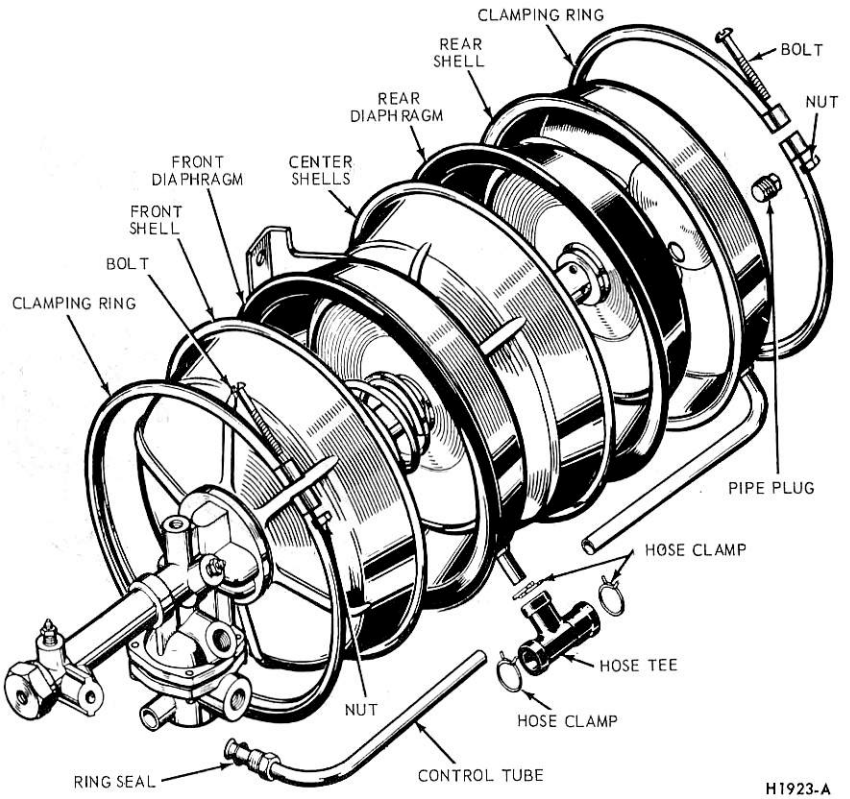

FIG. 3 Separating Booster Shells

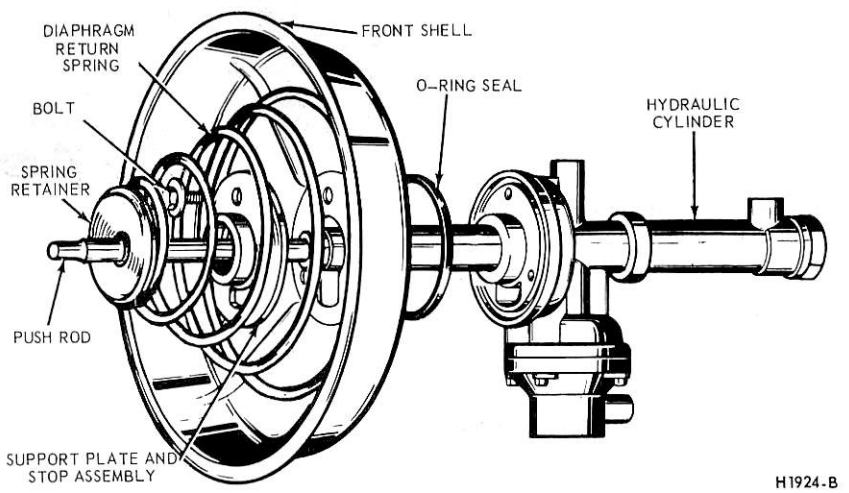

FIG. 4 Support Plate and Front Shell Removed

14. Install the residual pressure check valve in the end fitting. Then, assemble the check valve spring and washer in the end fitting and secure them with the snap ring.
15. Assemble the gasket on the end fitting and screw the fitting into the end of the hydraulic cylinder. Tighten the end fitting to 50-85 ft-lbs.
16. Position the ring seal in its groove around the flange of the hydraulic cylinder (Fig. 4).
17. Slide the small diameter end of the diaphragm return spring over the piston end of the hydraulic push rod.

Wet the hydraulic cylinder bore and hydraulic piston with clean brake fluid.

18. With the small coil of return spring bottomed against the spring retainer on the push rod, place the large coil of the spring inside the front shell with the hydraulic piston through the hole in the shell.
19. Compress the return spring slightly and guide the hydraulic piston, seal retainer, push rod cup, and push rod bearing into the cylinder bore. Seat the hydraulic cylinder flange against the front shell with the ring seal in place. Position the support plate and stop assembly on the other side of the shell and install the three bolts that secure the stop assembly and front shell to the hydraulic cylinder. Release pressure on the spring.
20. Lightly coat both sides of the beads of front and rear diaphragms with talcum powder or a silicon lubricant.
21. Guide the rear shaft onto the push rod and align the scribe marks on the shell flanges next to the front diaphragm. Press the shells together to seat the bead of the front diaphragm in the shell flanges all the way around.
22. Assemble the clamping ring on the shell flanges with scribe marks aligned and secure it with the screw and nut. Tap the ring lightly with a rawhide hammer while tightening the screw and nut to 30-40 in-lbs.
23. Press the rear shells together with the shells aligned to the scribe marks and the bead of the rear diaphragm in the shell flanges all the way around. Assemble the clamping ring on the shell flanges with the scribe marks aligned and secure it with the screw and nut. Tap the ring and tighten as in Step 22.
24. Attach the hose tee to the control tube on the rear shell and to the hose nipple on the center shells using hose clamps.
25. Assemble the ring seal on the end of the control tube and nut assembly and attach the tube to the hose tee with a hose clamp. Screw the tube nut into the control valve port. Tighten the tube nut to 80-120 in-lbs.
26. If removed, assemble the pipe plug in the rear shell and tighten it to 12-20 ft-lbs. If the bleeder screws were removed, assemble the screws in the hydraulic cylinder and tighten them to 10-15 ft-lbs. **The tube seat inserts in the input and output hydraulic ports should not be removed except to replace a damaged tube seat.**

PART 12-58 Vacuum Brake Booster — Single Diaphragm, Dash-Mounted (Midland)

Applies to F-, B-500-600 and LN-Series with Single or Split Hydraulic Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BOOSTER		Removal and Installation	58-03
Air Check	58-02	PUSH ROD	
Description	58-01	Adjustment	58-02

DESCRIPTION

MIDLAND-ROSS DIAPHRAGM TYPE — DASH-MOUNTED BOOSTER

The single diaphragm type vacuum booster is a self-contained vacuum-hydraulic power braking unit. It is of the vacuum-suspended type which utilizes engine intake manifold vacuum and atmospheric pressure for its power. It consists of three basic elements combined into a single unit as shown in Fig. 1.

The three basic elements are:

1. A vacuum power chamber which consists of a front and a rear shell, a diaphragm, a diaphragm plate, a hydraulic push rod and a vacuum diaphragm return spring.
2. A mechanically-actuated control valve, integral with the vacuum power diaphragm, which controls the degree of power brake application or release in accordance with the foot pressure applied to the valve operating rod through the brake pedal linkage.
3. A hydraulic dual, or single, master cylinder, which supplies hydraulic pressure to the brake system (Figs. 2 and 3).

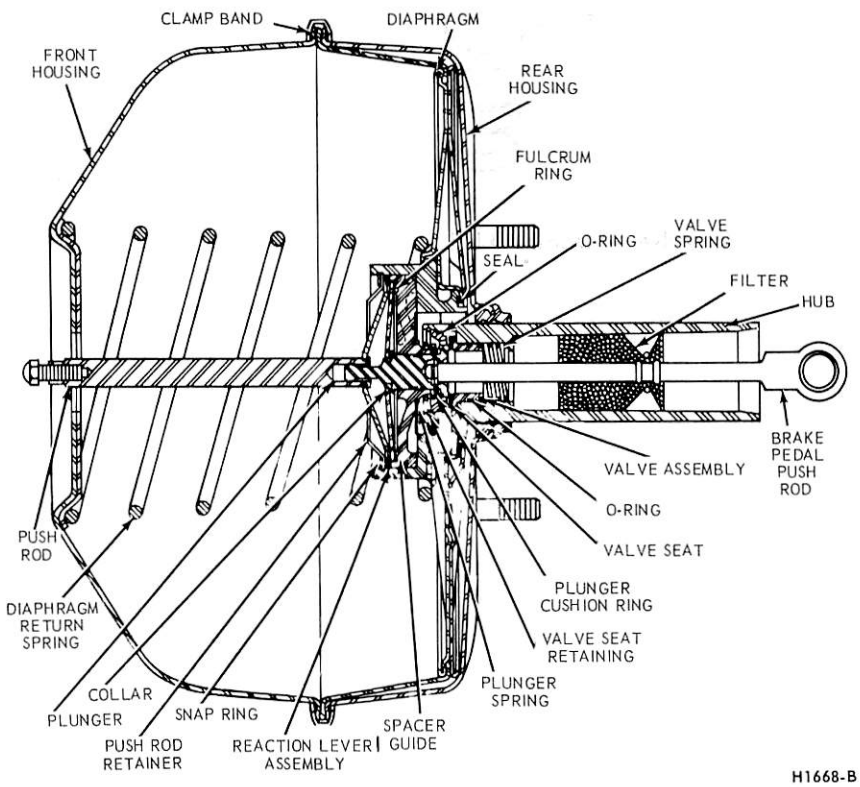

FIG. 1 Midland-Ross Dash-Mounted Booster

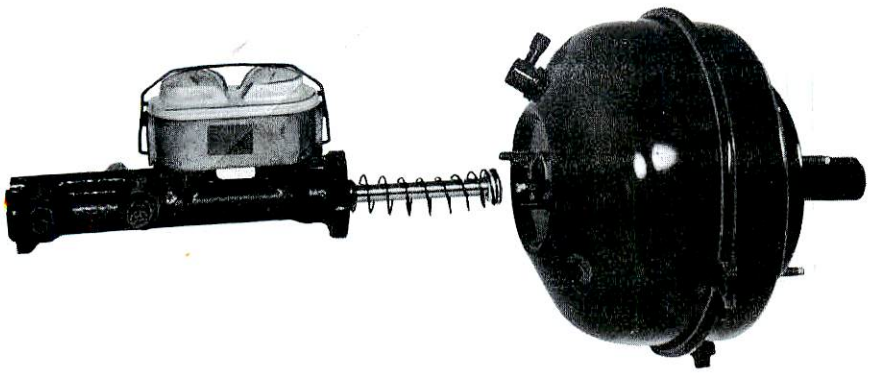
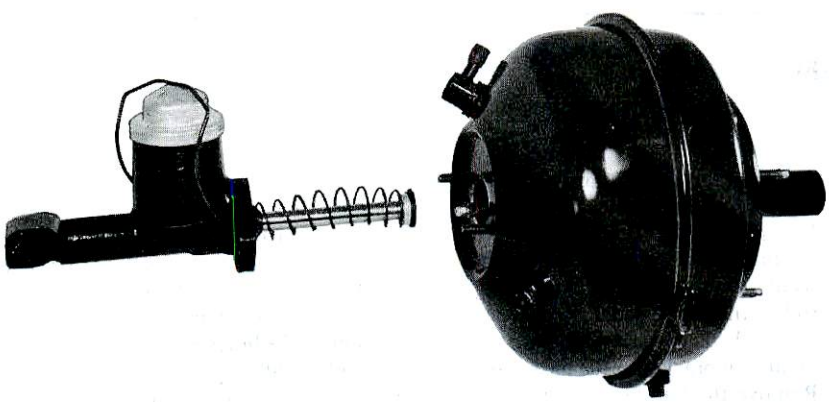


H1983-A

FIG. 2 Booster with Dual Master Cylinder (Split System)



H1984-A

FIG. 3 Booster with Single Master Cylinder (Single System)

ADJUSTMENTS

PUSH ROD

The push rod is provided with an adjustment screw to maintain the correct relationship between the booster control valve plunger and the master cylinder piston. If the plunger is too long, it will prevent the master cylinder piston from completely releasing hydraulic pressure and can cause the brakes to drag. If the plunger is too short, it will result in excessive pedal travel and an undesirable clunk in the booster area. Remove the master cylinder for access to the booster push rod.

To check the adjustment of the screw, fabricate a gauge of the dimensions shown in Fig. 2. Then place the gauge against the master cylinder mounting surface of the booster body as shown in Fig. 4. The push rod screw should be adjusted so that the end of the screw just touches the inner edge of the slot in the gauge.

Air Check

Whenever the master cylinder or booster has been repaired or replaced, the brake system must be checked for proper return flow of hydraulic brake fluid from the wheel cylinders to the reservoir of the master cylinder. This check will assure that the brake booster to master cylinder push rod is properly adjusted to allow the master cylinder compensating valve to open when the brake pedal is in the fully-released position.

The air check is made after the brake booster and master cylinder has been installed and before the master cylinder hydraulic line connection is made and the reservoir is filled with brake fluid.

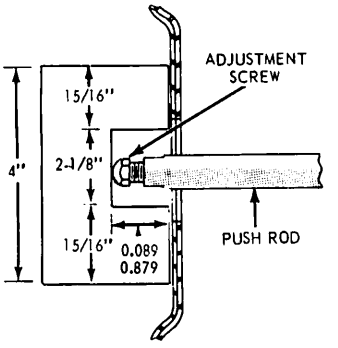
1. Connect the brake vacuum line to the vacuum booster, if required. Start the engine.
2. Carefully position the nozzle of an air hose to the master cylinder discharge port. Place a hand over the master cylinder reservoir and apply air pressure through the air hose nozzle.

Be careful not to allow dirt to enter into the system.

If free passage air pressure is felt on the hand located over the master cylinder reservoir, the brake booster

push rod is properly adjusted.

If no air pressure is felt on the hand located over the reservoir, the master cylinder must be removed and the push rod length shortened. To shorten the push rod length, turn the acorn-type screw on the brake booster push rod inward, one turn at a time, until the air check shows the brake master cylinder compensating valve is open.



H1665-B

FIG. 4 Push Rod Gauge Dimensions and Adjustment

REMOVAL AND INSTALLATION

MIDLAND DIAPHRAGM-TYPE DASH-MOUNTED BOOSTER

The brake booster is serviced as an assembly only.

Removal

1. Support the master cylinder with a prop from the underside.
2. Remove the master cylinder-to-booster attaching nuts.
3. Remove the clip that retains the master cylinder outlet line to the bracket on the dash panel.
4. Loosen the clamp that secures the manifold vacuum hose to the booster and remove the hose. Remove the reservoir hose from the booster unit, if so equipped.
5. Pull the master cylinder off the booster, and leave it supported by the prop far enough away to allow removal of the booster assembly.
6. From inside the cab, remove the eccentric bolt and lock nut that secure the booster valve operating rod to the brake pedal. Remove the nuts that retain the booster mounting bracket to the dash panel.
7. Remove the booster assembly from the engine compartment.

Installation

1. Mount the booster and bracket assembly to the engine side of the dash panel by sliding the bracket mounting studs and of the valve operating rod in through the holes in the dash panel.
2. From inside the cab, install the booster mounting bracket-to-dash panel attaching nuts.
3. Check the push rod adjustment as described in this part.
4. Position the master cylinder to the booster assembly, install the retaining nuts, and remove the prop.
5. Position the master cylinder outlet line to the bracket on the dash panel, and install the retaining clip.
6. Connect the manifold vacuum hose to the booster and secure with the clamp. Connect the reservoir hose to the booster if so equipped.
7. From inside the cab, connect the booster valve operating rod to the brake pedal with the eccentric bolt and lock nut. Adjust the brake pedal free travel as described in Part 12-02.
8. Start the engine and check the operation of the brake system.

PART 12-60 Vacuum Brake Booster — Single Diaphragm, Frame-Mounted (Midland)

Applies to P-500 Series Trucks

COMPONENT INDEX	Page	COMPONENT INDEX	Page
BOOSTER		BOOSTER - Continued	
Description	60-01	Removal and Installation	60-02
Disassembly and Assembly	60-02		

DESCRIPTION

MIDLAND (HI-POWER) DIAPHRAGM TYPE-FRAME MOUNTED BOOSTER

The frame-mounted diaphragm type vacuum booster consists of a vacuum chamber, a hydraulically actuated vacuum control valve, and a hydraulic cylinder, all in a single sealed unit (Fig. 1).

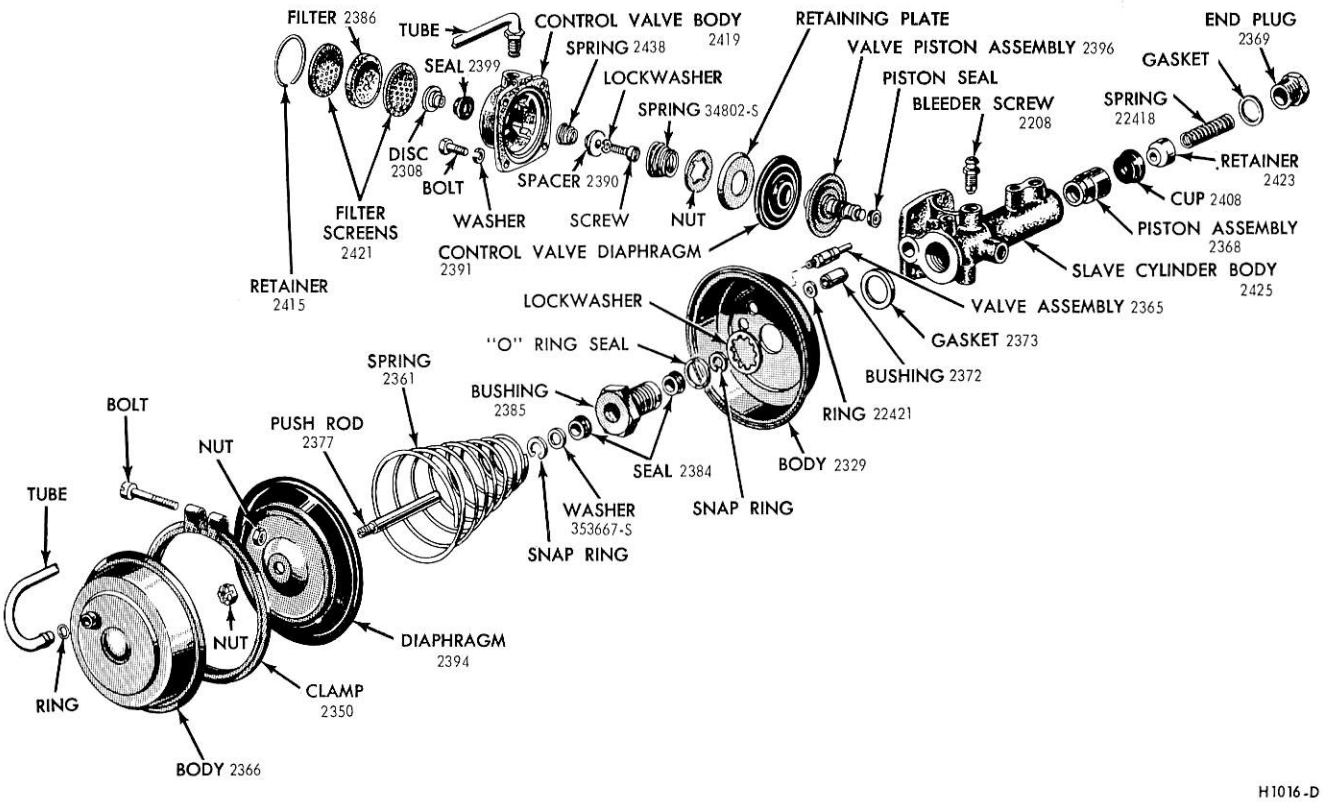


FIG. 1 Midland Hi-Power Vacuum Booster — Disassembled

REMOVAL AND INSTALLATION

Removal

1. With the engine stopped, depress the brake pedal several times to remove all vacuum from the booster system.
2. Disconnect the 2 hydraulic lines and vacuum hose from the booster.
3. Loosen the air breather hose clamp and disconnect the hose from the booster.
4. Remove the 3 mounting bolts and lockwashers and remove the booster.

Do not remove the breather or the vacuum check valve unless operating conditions indicate repairs are necessary.

Installation

1. Position the booster on the mounting bracket, and install the mounting bolts, using new lockwashers.
2. Connect the hydraulic lines to the booster. Tighten connections securely.
3. Connect the air intake hose to the control valve air inlet tube. Tighten the hose clamp securely. If necessary, clean the air inlet element.
4. Bleed the brake system as outlined under Hydraulic System Bleeding Part 12-01.
5. Connect the vacuum hose to the vacuum check valve (or tube) on the booster. Tighten the clamps securely.
6. Perform the checks and tests as outlined in Part 12-01.

OVERHAUL

MIDLAND (HI-POWER) BOOSTER

Disassembly

1. Remove the by-pass tube from both the control valve body and the rear body (Fig. 1).
2. Mark both halves of the diaphragm body with a scriber. Mark the flanges of the control valve body and the slave cylinder body so the parts can be assembled in their original positions.
3. Carefully remove the body clamp. Then, remove the rear body and the diaphragm with the return spring.
4. Remove the push rod, spring retainer and collar from the coils of the return spring.
5. Remove the valve body cover and gasket. Scribe a line on the side of the valve body cover and valve body.
6. Remove the valve body, spring, and the piston and diaphragm assembly from the slave cylinder body.
7. Remove the end plug, copper gasket, spring (and spring seat, on frame-mounted units) and spring retainer from the end of the slave cylinder.
8. Remove the piston cup and hydraulic piston assembly from the cylinder. If the assembly does not fall free of the cylinder bore, it may be pushed out by inserting the push rod in the bushing.
9. Remove the check valve retainer, check valve and return spring from the hydraulic piston.
10. Mount the slave cylinder body in a vise, and remove the push rod bushing, lockwasher, and front body from the slave cylinder body.
11. Remove the gasket, rubber seal, and transfer bushing from the slave cylinder body. Remove the 2 push rod bushing snap rings, and remove the washer and 2 seals from the bushing. Remove the O-ring seal from the outside diameter of the push rod bushing.
12. Remove the seal from the lower end of the control valve piston. Remove the seal from the piston boss.
13. Remove the retainer nut from the piston boss by prying the inner tangs of the nut away from the boss, and remove the diaphragm plate and control valve diaphragm.
14. Remove the screw, lock washer, spacer, spring, disc, and seal from the control valve body.

Assembly

1. Position a new seal in the control valve body. Assemble the spring and spacer in the valve body and secure with the screw and lockwasher. Tighten the screw securely.
2. Position the control valve diaphragm and plate and secure it in place with the attaching nut.
3. Install the control valve piston seal on the piston.
4. Insert the check valve spring, valve, and retainer in the hydraulic piston. Be sure the check valve floats freely and does not bind in the bore.
5. Install the transfer bushing, rubber seal, and gasket on the front body end of the slave cylinder body.
6. Install the push rod seals, washer, and snap rings in the push rod bushing. Both push rod seals should be installed with the open end of the seal facing the slave cylinder body. Install the lockwasher over the end of the bushing. Install the bushing seal.
7. Mount the slave cylinder body in a vise. Position the front body over the end of the slave cylinder, inserting the transfer bushing with proper hole in the front body.
8. Thread the push rod bushing in place. Be sure the front body seats squarely on the slave cylinder body, and tighten the bushing securely.
9. Coat the piston bores in the slaves cylinder body with brake fluid. Dip the hydraulic cylinder piston, seals, spring retainer, and spring in the brake fluid.
10. Install the hydraulic piston in the slave cylinder bore with the recessed end (or the large bore of the piston) toward the push rod bushing. Carefully position the piston cup with the recessed end toward the large spring, spring retainer, and spring on top of the piston.

On a frame-mounted booster, install the spring seat in the spring coils.

11. Position a new copper gasket on the end plug and screw the plug in the slave cylinder. Tighten the end plug securely.
12. Dip the control valve piston and diaphragm in the brake fluid. Position the control valve spring on the diaphragm with the small end of the spring over the piston boss.
13. Position the control valve body over the spring, align the scribe marks, install the valve body on the slave cylinder body and secure with 4 attaching bolts and lockwashers. Tighten the bolts securely.
14. Position a new gasket on the control valve body, position the valve body cover over the gasket and secure the cover with 4 bolts and lockwashers. Tighten the bolts securely.
15. Position the collar over the threaded end of the push rod. Position the spring retainer in the spring as shown in the insert in Fig. 1. Insert

the push rod and collar in the coils of the spring and through the retainer. Position the diaphragm over the threaded end of the push rod and secure it with the push rod nut. Tighten the nut securely. After the nut is tightened coat the threads of the push rod with shellac to prevent leakage. Coat the push rod with brake fluid.

16. Place the return spring over the push rod bushing.
17. Place the rear body on top of the diaphragm with the scribe mark on the rear body in alignment with that on the front body. Compress the return spring, and install and tighten the clamp, making certain the diaphragm bead is properly positioned between the 2 halves of the body.
18. Install the by-pass tube.

PART 12-70 Parking Brake—Cable Actuated, Rear Wheels

Applies To Bronco, E-100-300; F-100-350 Series Truck

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTMENT	70-03	PARKING BRAKE EQUALIZER TO CONTROL ASSEMBLY CABLE Removal and Installation	70-06
DESCRIPTION	70-01	PARKING BRAKE EQUALIZER TO REAR WHEEL CABLE Removal and Installation	70-07
PARKING BRAKE CONTROL Removal and Installation	70-04		

DESCRIPTION

CABLE ACTUATED REAR WHEEL PARKING BRAKE

On F-100, F-250, F-350, E-100, E-200, E-300 and Bronco models, a cable actuated parking brake assembly is contained in each rear wheel brake assembly (Figs. 1 and 2).

On the F-100, F-250, F-350, E-100, E-200, E-300 and Bronco models, the manually operated parking brake lever cable is routed to the equalizer lever (Figs. 3, 4, 5, 6, 7 and 8), which through the equalizer assembly and brake cables connects to the parking brake lever assembly in each rear wheel.

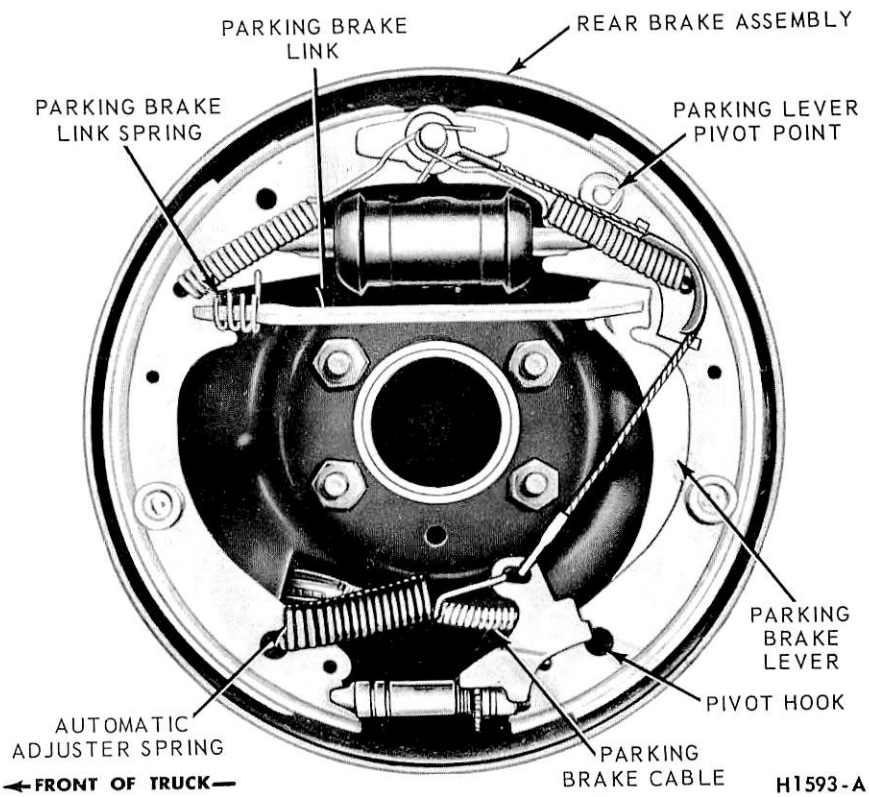

FIG. 1 Parking Brake Assembly—Cable Operated— F-100-250, E-100-200 and Bronco

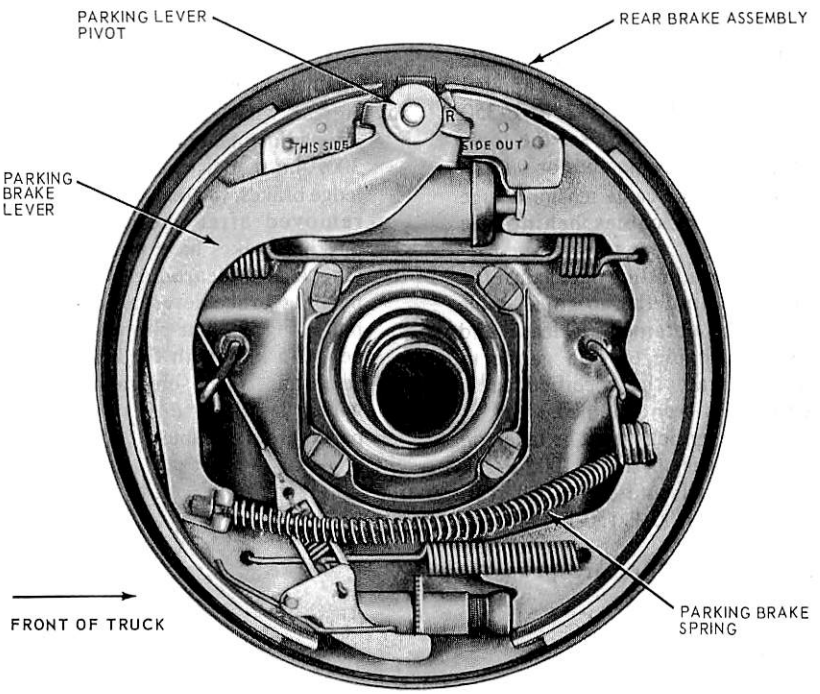

FIG. 2 Parking Brake Assembly—Cable Operated—(E-300, F-250-350)

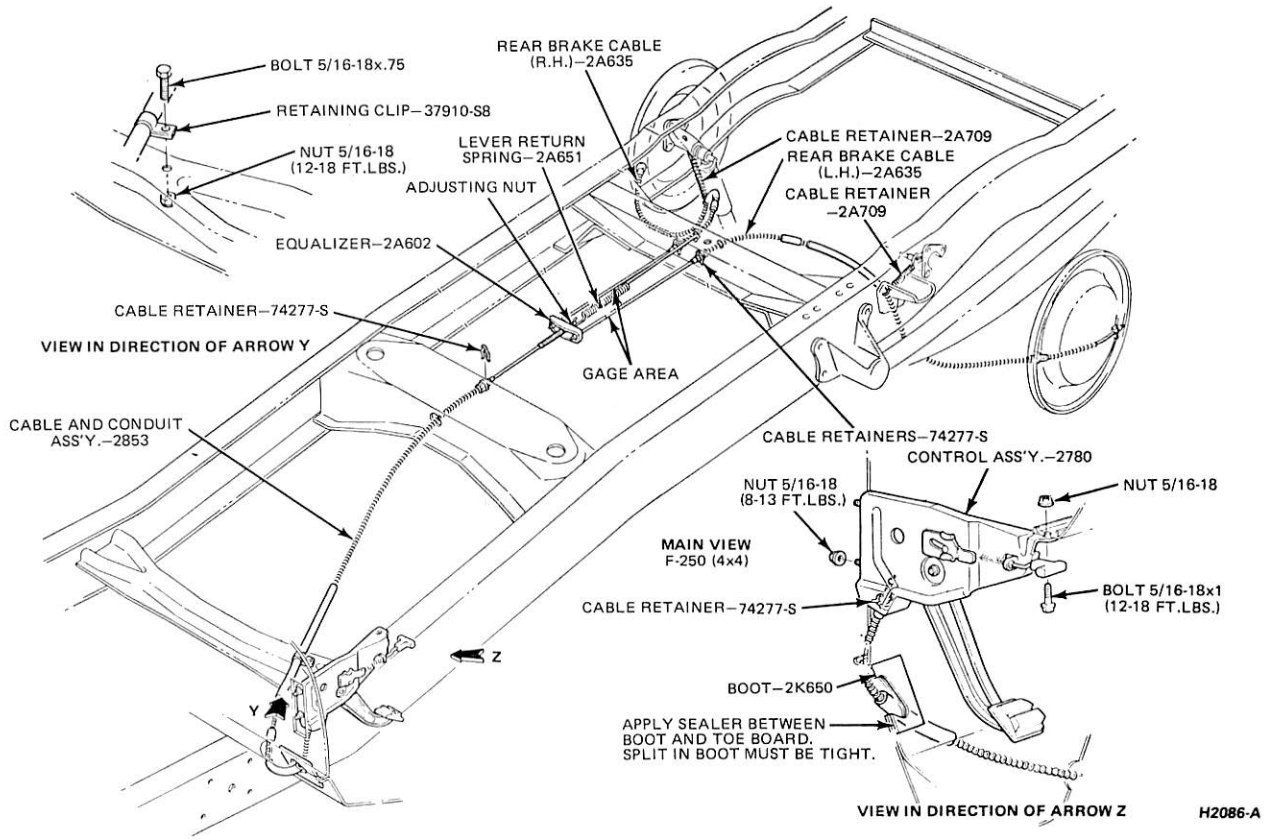

FIG. 3 Parking Brake System—F-250 (4 x 4)

ADJUSTMENT

CABLE ACTUATED REAR WHEEL PARKING BRAKE

Adjust the service brakes before attempting to adjust the parking brake cables.

Place the parking brake lever in the fully released position, then check the slack in the parking brake two rear cables.

The cables should be tight enough to provide full application of the rear brake shoes, when the parking brake lever or foot pedal is placed in the fully applied position, yet loose enough to ensure complete release of the brake shoes when the lever is in the released position.

If the cables are loose, adjust them as follows:

1. Set the parking brake control handle (if applicable) in the fully applied position. On F-100, F-250, F-350 and Bronco o models set the foot-350 pedal at two notches or clicks.
2. Attach a brake cable tension gauge to the brake cables behind the equalizer.
3. Tighten the adjusting nut against the equalizer until the specified cable tension is obtained. Release and reset the cable tension gauge to make certain the specified cable tension has been obtained.

   The cable tensions **must** be taken on **both rear cables** on the E-100, E-200 and E-300 models and on the left rear cable only for F-100, F-150, F-350, and Bronco models.
4. When the cables are properly adjusted, tighten the lock nut against the equalizer.
5. If rear wheel brake drag is noted after adjustment on F-250, F-350, E-300, and models equipped with web ledge brakes, the rear drums must be removed after the service and parking brakes have been adjusted. Check the clearance betweenthe parking brake lever and the cam plate (Fig. 9). The clearance should be 0.015 inch with the brakes fully released. If the clearance is not within specifications, readjust the parking brake cable.

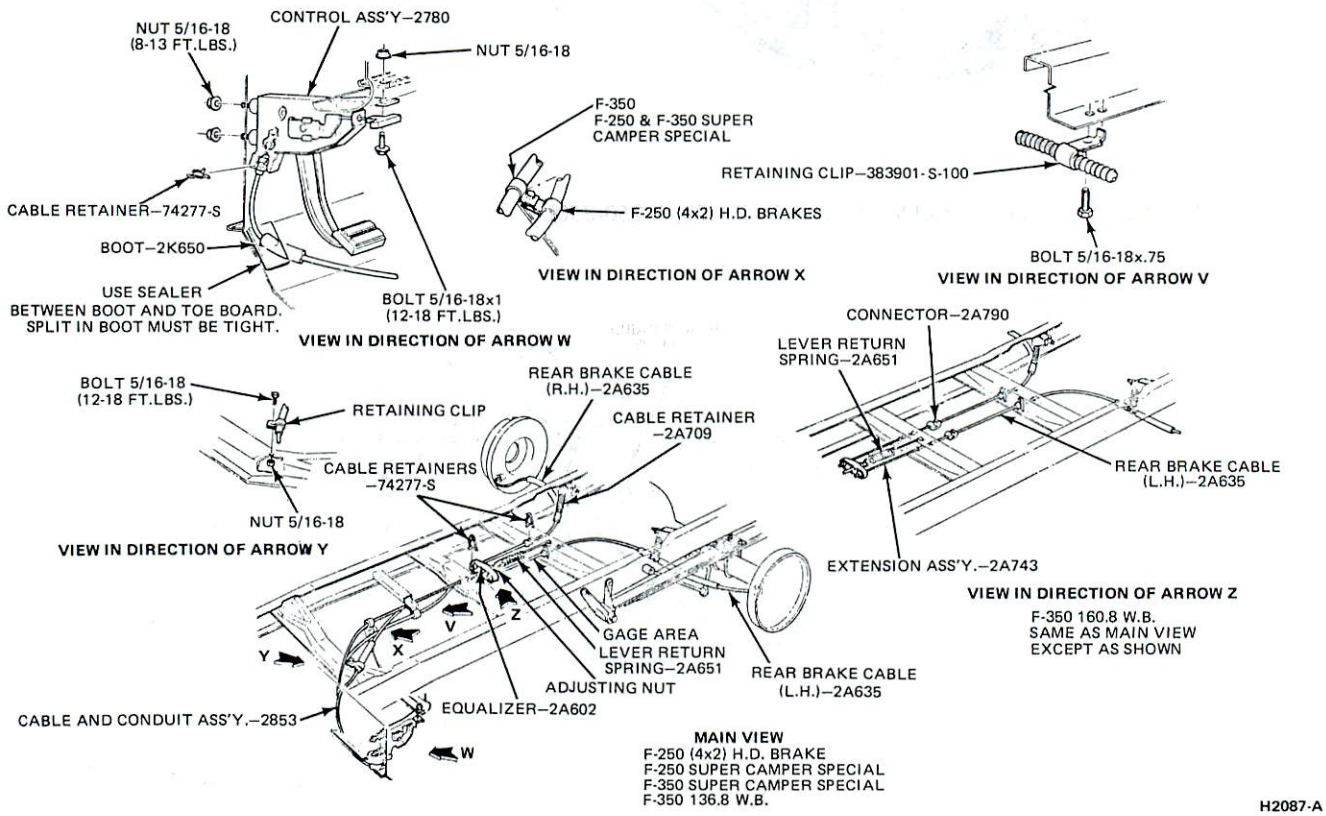

FIG. 4 Parking Brake System—F-250 (4 x 2), F-350

REMOVAL AND INSTALLATION

PARKING BRAKE CONTROL

F-100-350 SERIES

Removal

1. Loosen the adjusting nut at the equalizer (Fig. 3, 4 and 5).
2. Working under the left front fender, remove the two nuts attaching the parking brake control assembly to the dash panel.
3. Working under the instrument panel, remove the bolt and nut attaching the control assembly to the lower flange of the instrument panel.
4. Remove the forward ball end of the parking brake cable from the control assembly clevis. Remove the hair pin retainer retaining the cable assembly to the control and remove the control.

Installation

1. Connect the forward ball end of the parking brake cable to the clevis of the control assembly and install the cable assembly to control retainer.
2. Position the control assembly to the lower flange of the instrument panel and install the attaching bolt and nut.
3. Working under the left front fender, install and tighten the two nuts attaching the parking brake control assembly to the dash panel.
4. Adjust the parking brake equalizer lever to its original position. Check cable tension and adjust the parking brake, if necessary, following the instructions given in Parking Brake Adjustment.

BRONCO

Removal

1. Loosen the adjusting nut at the equalizer (Fig. 6).
2. Open the hood and remove the two nuts attaching the parking brake control assembly to the dash panel.
3. Working under the instrument panel, remove the bolt and nut attaching the control assembly to the lower flange of the instrument panel.
4. Remove the forward ball end of the parking brake cable from the control assembly clevis and remove the control.

Installation

1. Connect the forward ball end of the parking brake cable to the clevis of the control assembly.
2. Position the control assembly to the lower flange of the instrument panel and install the attaching bolt and nut.
3. Working in the engine compartment, install and tighten the two nuts attaching the parking brake control assembly to the dash panel. Lower the hood.
4. Adjust the parking brake equalizer lever to its original position. Check cable tension and adjust the parking brake, if necessary, following the instructions given in Parking Brake Adjustment.

ECONOLINE

Removal

Refer to Figures 7 and 8.

1. Push the equalizer lever slightly forward, and disconnect the ball end of the cable from the equalizer lever.
2. Remove the bolts retaining the parking brake handle assembly to

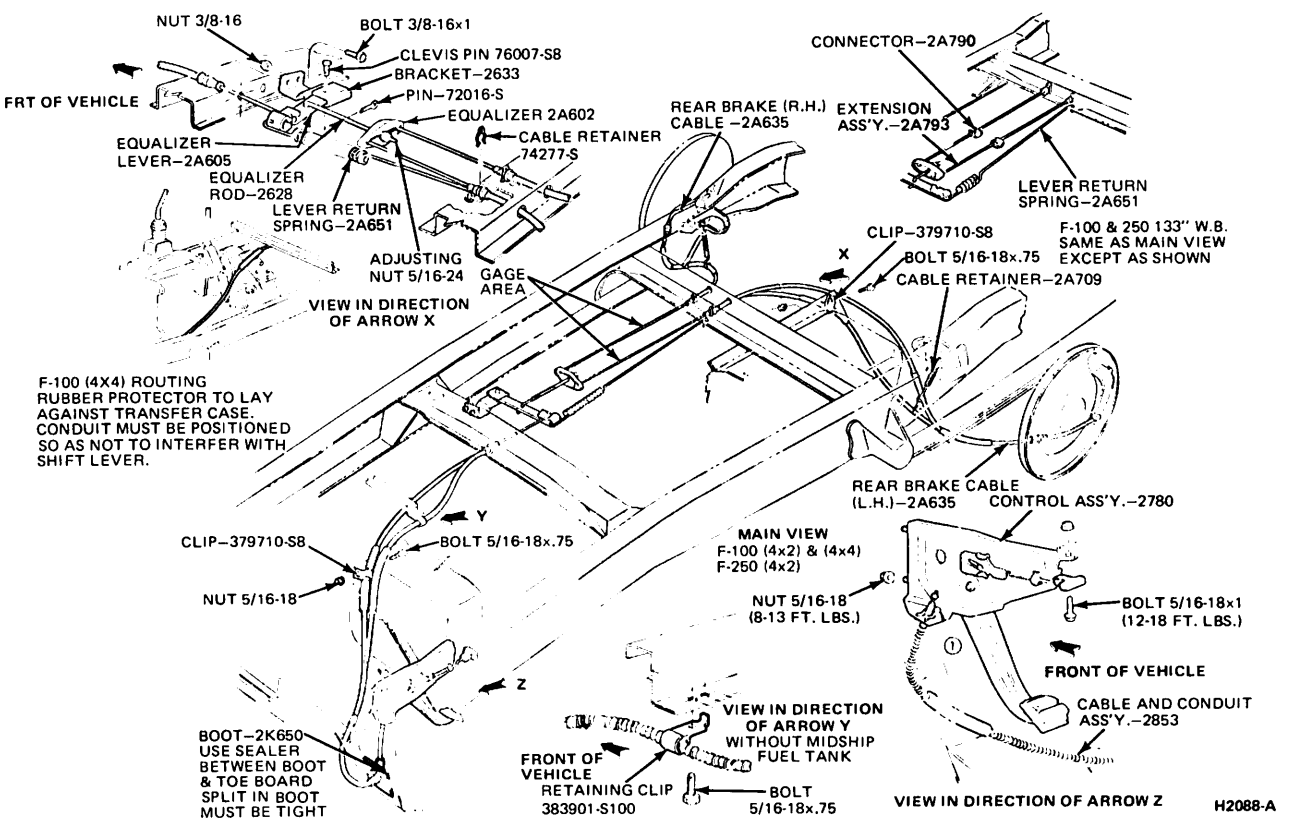

FIG. 5 Parking Brake System—F-100, F-250

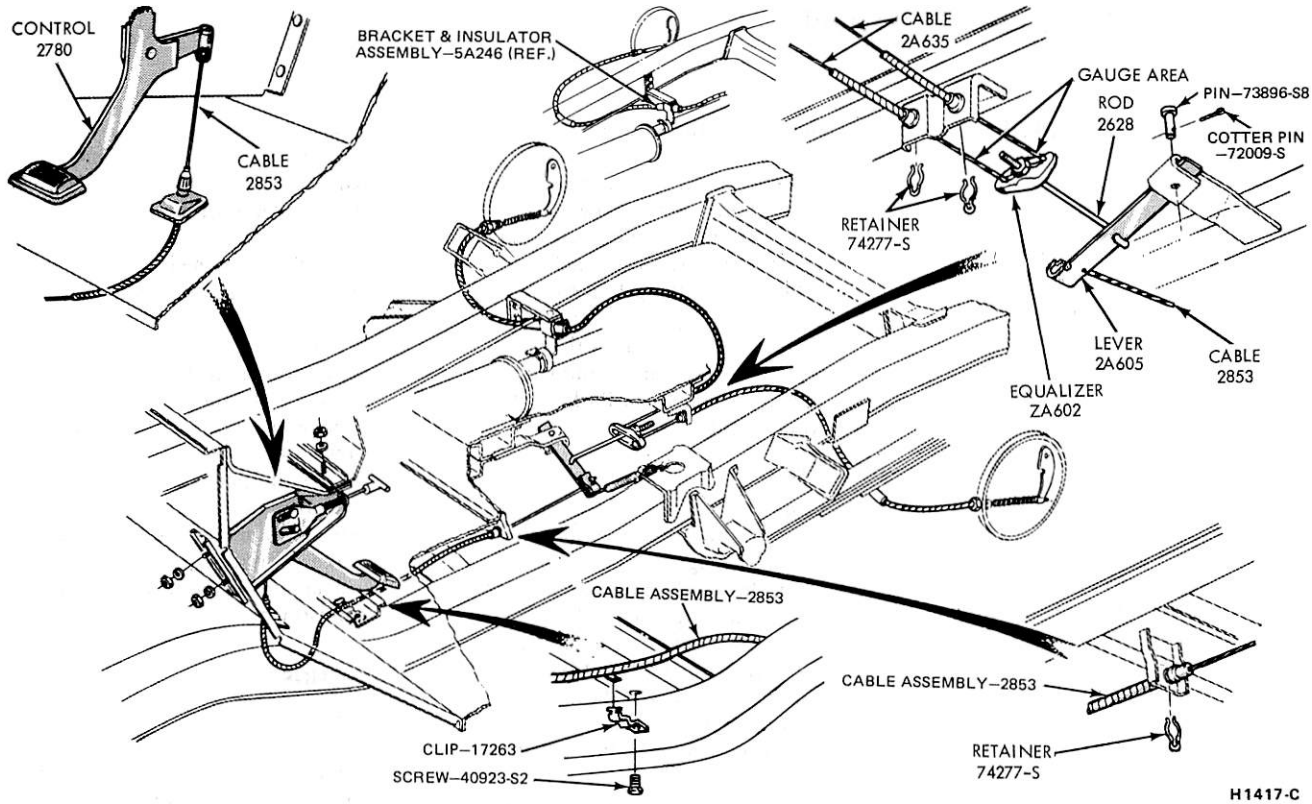

FIG. 6 Parking Brake System—Bronco

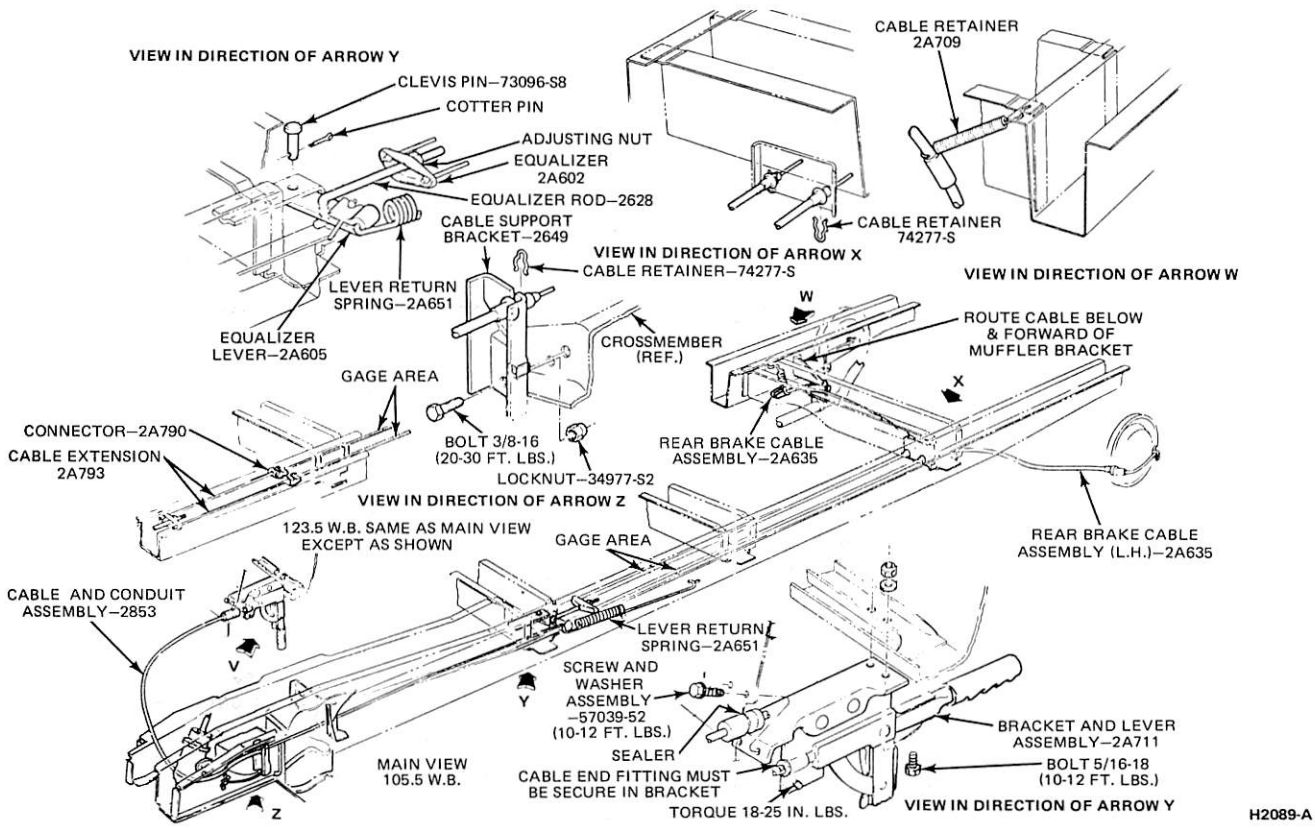

FIG. 7 Parking Brake System—E-100, E-200

the dash panel and instrument panel. Remove the handle assembly.

Installation

1. Position the parking brake handle assembly under the instrument panel and install the bolts retaining the handle to the dash panel and instrument panel.
2. Push the equalizer lever slightly forward, and insert the ball end of the cable in the slot on the equalizer lever.
3. Adjust the parking brakes.

PARKING BRAKE EQUALIZER TO CONTROL ASSEMBLY CABLE

Removal

1. Raise tvehicle on a hoist. Push the equalizer lever slightly forward, and disconnect the cable rear (ball) end from the lever.
2. Remove the parking brake cable retaining U-clip at the crossmember.
3. Lower the vehicle, open the hood, and remove the cable retaining clamp on the fender apron.
4. Remove the cable retaining U-clip at the handle assembly. Remove the cable from the vehicle.

On F-100 through F-350 vehicles it will be necessary to remove the access cover located on the body left front mounting reinforcement. With the use of a fish-wire or cord attached to the control lever end of the cable, remove the cable from the vehicle.

Installation

1. Position the new cable through the dash panel and connect it to the parking brake handle assembly. Secure the cable to the handle assembly with the U-clip. On an F-100 through F-350 vehicle, transfer the fish-wire or cord to the new cable. Position the cable to the vehicle, routing the cable through the dash panel and through the crossmember. Remove the fish-wire and secure the cable to the control with the retaining clip.
2. Install the cable retaining clamp to the fender apron, and raise the vehicle on a hoist.
3. Route the cable through the crossmember(s) and secure in place with the U-clip(s).
4. Push the equalizer lever forward and connect the cable rear (ball) end to the lever. Adjust the parking brake cable at the equalizer assembly.

On a F-100 through F-350 vehicle, install the access cover on the body left-front mounting reinforcement.

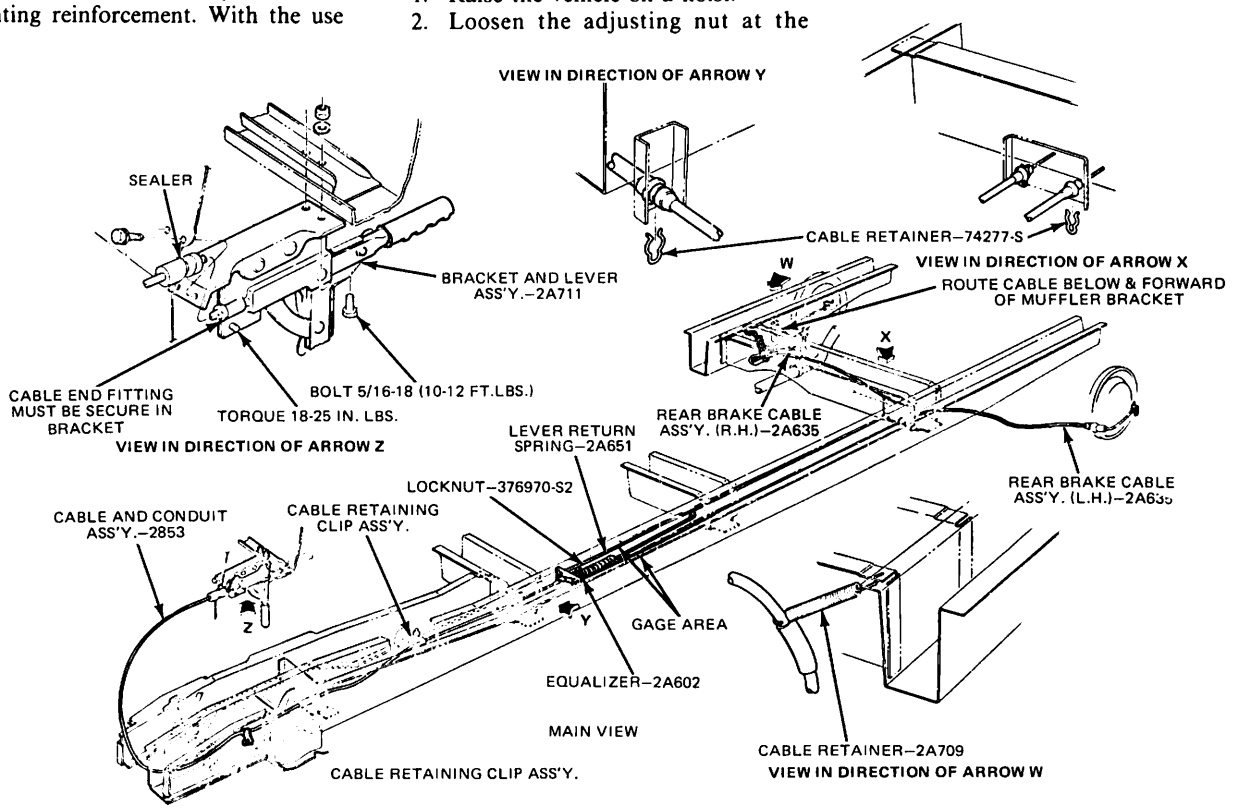
BRONCO

Removal

1. Raise the vehicle on a hoist.
2. Loosen the adjusting nut at the equalizer assembly (Fig. 5) and remove ball end of the brake control to equalizer cable from the equalizer arm. Remove the clip retaining the cable housing to the bracket.
3. Lower the vehicle.
4. From inside of vehicle, disconnect the cable at the parking brake control clevis.
5. Raise the vehicle on a hoist.
6. Pull the parking brake control to equalizer cable through the hole in the dash panel and remove it from the vehicle.

Installation

1. Position the parking brake control to equalizer cable upward through the hole in the dash panel. Position the cable to the mounting bracket.
2. Lower the vehicle.
3. Connect the cable to the parking brake control clevis.
4. Raise the vehicle on the hoist.
5. Position the cable housing to the bracket and install the retaining clip.
6. Connect the ball end of cable to the equalizer arm and install the adjusting nut.
7. Adjust the parking brakes.
8. Lower the vehicle. Check the operation of the parking brake control.



H2090-A

FIG. 8 Parking Brake System—E-300

ECONOLINE

Removal

1. Remove the parking brake handle as outlined in this section.
2. Remove the ball end of the cable from the parking brake handle.
3. Remove the cable clip at the frame crossmember below the steering gear.
4. Remove the ball end of the cable from the equalizer and remove the cable.

Installation

1. Place the cable ball in the equalizer slot.
2. Install the parking brake handle as outlined in this section.
3. Push the equalizer slightly forward and install the cable ball end in the parking brake handle.
4. Install the retaining clip at the frame crossmember below the steering gear.

PARKING BRAKE EQUALIZER TO REAR WHEEL CABLE

Removal

1. Raise the vehicle and remove the hub cap, wheel, and brake drum. Loosen the lock nut on the equalizer rod and disconnect the cable from the equalizer.
2. Remove the horseshoe-type clip that retains the cable housing to the frame bracket and pull the cable and housing out of the bracket.
3. Working on the wheel side (Fig. 1), compress the prongs on the cable retainer so that they can pass through the hole in the carrier plate. Draw the cable retainer out of the hole.
4. With the spring tension off the parking brake lever, lift the cable out of the slot in the lever, and remove the cable through the carrier plate hole.

Installation

1. Pull enough of the cable through the housing so that the end of the cable may be inserted over the slot in the parking brake lever. Pull the excess slack from the cable and insert the cable housing into the carrier plate access hole so that the retainer prongs expand.
2. Thread the front end of the cable housing through the frame bracket and install the horseshoe-type retaining clip. Insert the ball end of the cable into the equalizer and tighten the lock nut on the equalizer slightly.

If the vehicle is equipped with web ledge brakes, check the clearance between the parking brake operating lever and the cam plate (Fig. 4). The clearance should be 0.015 inch with the brakes in the fully released position.

3. Install the rear brake drum, wheel, and hub cap, then adjust the rear brake shoes.
4. Tighten the lock nut on the equalizer rod until the slack is taken out of the cables.
5. Rotate both rear wheels to make sure that the parking brakes are not dragging.

Removal and Installation	77-03	Adjustment	77-02

DESCRIPTION

EXTERNAL CONTRACTING BAND TYPE PARKING BRAKE

The band type parking brake consists of a brake drum bolted to the transmission main shaft companion flange, and an external contracting type band mounted on the rear of the transmission (Figs. 1 and 2).

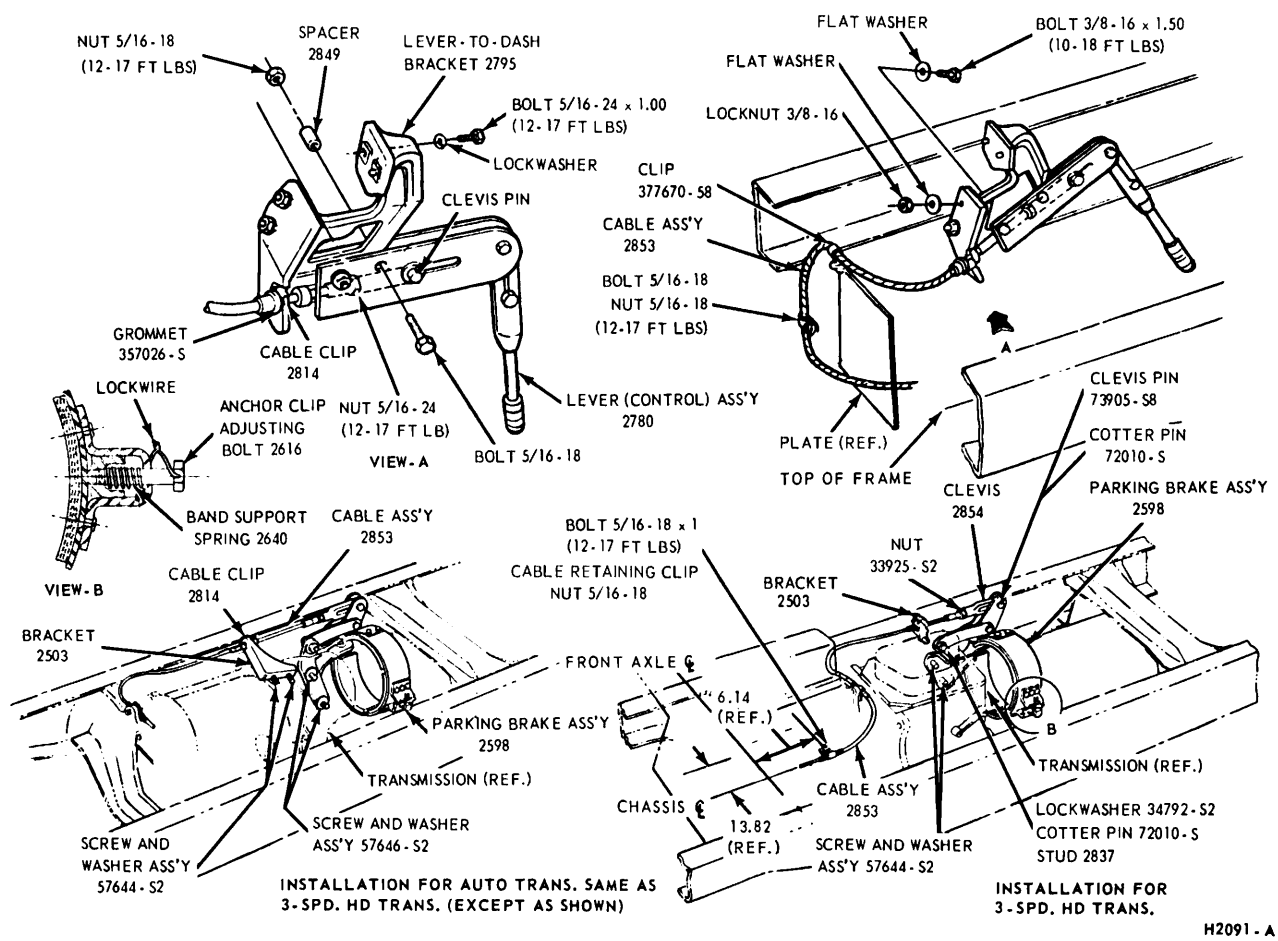

FIG. 1 External Band Type Parking Brake System

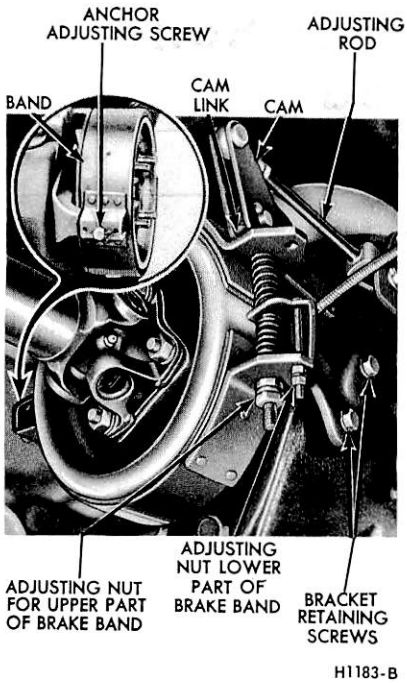

FIG. 2 External Band Adjustment

ADJUSTMENTS

PARKING BRAKE LEVER ADJUSTMENT

The orscheln parking brake (Fig. 1) is over center locking type. It is adjusted (while in the released position) by turning the lever knob. When properly adjusted, it pulls over center with a distinct click. No other adjustment is normally required.

EXTERNAL BAND ADJUSTMENT

1. On cable-controlled parking brakes (Fig. 1), move the parking brake lever to the fully released-position.
2. Check the position of the cam to make sure the flat portion is resting on the brake band bracket. If the cam is not flat with the bracket, remove the clevis pin from the upper part of the cam, and adjust the clevis rod to allow the flat portion of the cam to rest on the brake band bracket. Install the clevis pin and cotter pin (Fig. 2).
3. Remove the lock wire from the anchor adjusting screw, and turn the adjusting screw clockwise until a clearance of 0.010 inch is established between the brake lining and the brake drum at the anchor bracket. Install the lock wire in the anchor adjusting screw.
4. Loosen the lock nut on the adjusting screw for the lower half of the brake band, and adjust the screw to establish a 0.010 inch clearance between the lining and the brake drum at the lower half of the brake band (Fig. 2). Tighten the lock nut.
5. Turn the upper band adjusting rod nut until a 0.010 inch clearance is established between the upper half of the band and the drum.

REMOVAL AND INSTALLATION

BAND AND DRUM

Removal

1. Shift the transmission into low gear and disconnect the drive shaft companion flange from the transmission output shaft flange by removing the four nuts (Fig. 2).
2. Apply the parking brake, remove the transmission output shaft flange attaching nut, then release the parking brake.
3. Remove the cotter pin and clevis pin, and disconnect the adjusting rod from the cam.
4. Remove the cotter pin and clevis pin, and remove the cam link from the cam.
5. Remove the lock wire and the anchor adjusting screw.
6. Remove the brake band adjusting bolts and nuts.
7. Remove the brake bracket retaining cap screws.
8. Lift the brake band and lining assembly off the drum.
9. Inspect the brake lining, and replace it if the distance between the brake lining surfaces and the top of the rivet is less than 1/32 inch.

When relining a parking brake band, follow the procedure used in Part 12-01.

10. Inspect the drum braking surface. If the drum is rough or scored, it should be replaced. Remove the drum and output shaft flange as an assembly.

Installation

1. Position the parking brake drum and output shaft flange assembly to the transmission output shaft, and install the attaching nut.
2. Position the parking brake band assembly over the drum, and install the bracket attaching screws.
3. Install the brake band adjusting bolt and nuts and springs.
4. Connect the cam link to the lower end of the cam with clevis and cotter pin.
5. Connect the adjusting rod to the upper end of the cam with clevis and cotter pin.
6. Adjust the parking brake, and install a lock wire in the anchor adjusting screw.
7. Apply the parking brake, torque the transmission output shaft flange nut to specifications, then release the parking brake.
8. With the transmission in low gear, connect the drive shaft at the flange and torque the four attaching nuts.

BAND ONLY

Removal

Refer to Figure 2.

1. Disconnect the drive shaft from the output flange by removing the four nuts.
2. Disconnect the handbrake linkage at the cam.
3. Disconnect the cam link from the transmission case stud.
4. Remove the two bolts retaining the parking brake bracket to the transmission.
5. Remove the lock wire and remove the anchor adjusting screw.
6. Loosen the brake adjusting bolts and nuts.
7. Remove the brake shoe assembly.
8. Remove the actuating linkage and bracket from the brake band.
9. Reline the brake band as outlined in Part 12-01.

Installation

1. Install the linkage and bracket on the brake band.
2. Position the brake band with linkage and bracket to the drum and anchor.
3. Install the anchor adjusting screw.
4. Install the two bracket to transmission retaining screws.
5. Connect the cam link to the transmission case stud.
6. Connect the hand brake linkage at the cam.
7. Connect the drive shaft to the output flange and install the four nuts.
8. Adjust the parking brake.

DRUM ONLY

Removal

Refer to Figure 2.

1. Disconnect the drive shaft by removing the four nuts and lock washers at the companion flange.
2. Back off the parking brake adjustment.
3. Remove the retaining nut and remove the brake drum and output shaft flange as a unit.
4. Separate the output flange from the brake drum.

Installation

1. Position the brake drum to the output shaft flange.
2. Install the drum and flange assembly on the output shaft and install the retaining nut. Tighten the nut to specifications.
3. Position the drive shaft and install the four nuts and lock washers.
4. Adjust the parking brake.

PART 12-79 Parking Brake-Internal Shoe, Transmission Mounted

Applies To F500 Thru LTS 900-Series Trucks

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION	79-01	PARKING BRAKE LEVER Adjustment	79-02
NINE-INCH DIAMETER DRUM Adjustment	79-02	TWELVE-INCH DIAMETER DRUM Adjustment	79-02
Removal and Installation	79-03	Removal and Installation	79-02

DESCRIPTION

INTERNAL EXPANDING SHOE TYPE PARKING BRAKE

The internal shoe-type parking brake (Figs. 1 and 2), mounted on the transmission includes a brake drum attached to the drive shaft (or coupling shaft), two brake shoes, an actuating cam mechanism, and cable or rod-type linkage connected to a parking brake lever (Fig. 3).

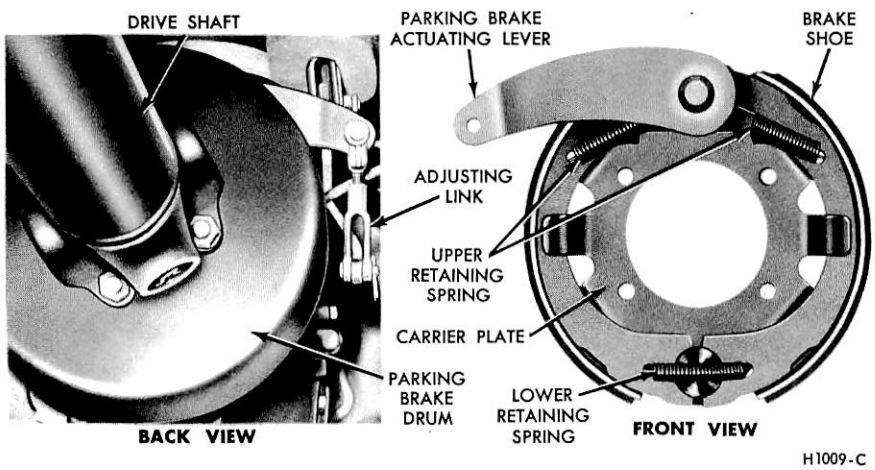

FIG. 1 Parking Brake—Transmission Mounted (9-inch Drum Shown)

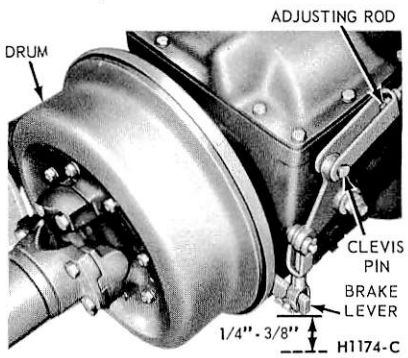

FIG. 2 Parking Brake—Transmission Mounted (12-inch Drum Shown)

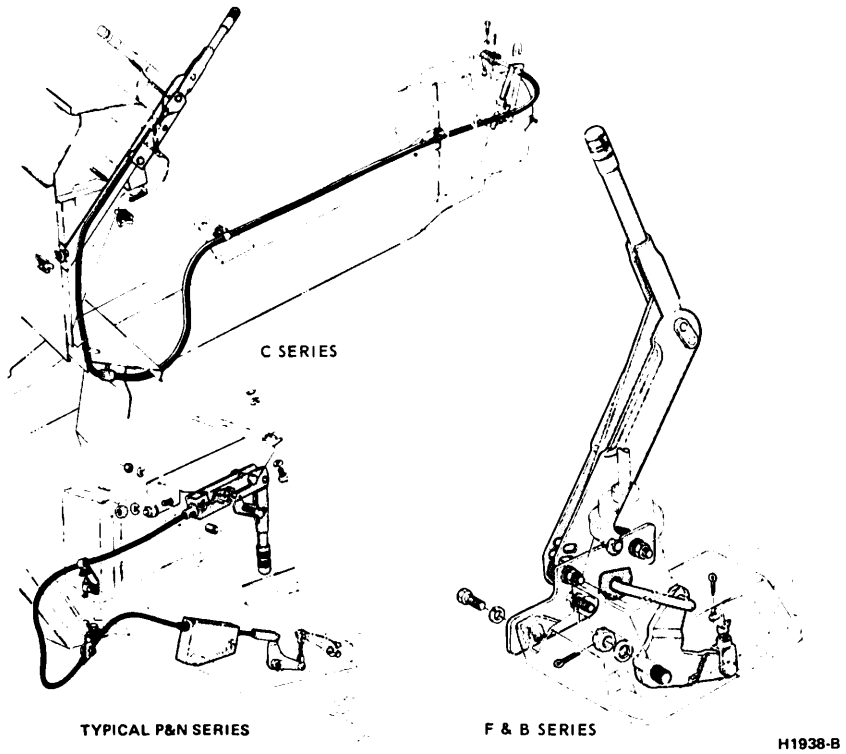

FIG. 3 Parking Brake Controls

ADJUSTMENTS

NINE-INCH DIAMETER DRUM ADJUSTMENT

1. Release the parking brake lever in the cab.
2. From under the truck, remove the cotter pin from the parking brake linkage adjusting clevis pin (Fig. 1). Remove the clevis pin.
3. Lengthen the parking brake adjusting link by turning the clevis. Continue to lengthen the adjusting link until the shoes seat against the drum when the clevis pin is installed.
4. Remove the clevis pin and shorten the linkage adjustment until there is 0.010 inch clearance between the shoes and the drum. The measurement should be taken at all points around the drum with the clevis pin installed.
5. Install a new cotter pin in the clevis retaining pin and check the brake operation.

TWELVE-INCH DIAMETER DRUM ADJUSTMENT

There is no internal adjustment on this brake. Adjustment is made on the linkage. Remove the clevis pin, loosen the nuts on the adjusting rod, and turn the clevis on the rod until a 1/4-3/8 inch free play is obtained at the brake lever (Fig. 2). Tighten the nuts, and connect the clevis to the bellcrank with the clevis pin.

PARKING BRAKE LEVER ADJUSTMENT

VEHICLES EQUIPPED WITH ORSCHELN LEVER

The Orscheln parking brake (Fig. 3) is the over center locking type. It is adjusted (while in the released position) by turning the lever knob. When properly adjusted, it pulls over center with a distinct click. No other adjustment is normally required.

REMOVAL AND INSTALLATION

INTERNAL SHOE TYPE PARKING BRAKE

Removal

1. Remove the universal joint assembly and drive shaft from the parking brake drum.
2. Remove the drum. Disconnect the parking brake actuating lever from the linkage.
3. On all transmissions except Transmatic Drive, remove the transmission spline flange. Remove the bolts retaining the carrier plate to the transmission housing. Slide the plate with the brake shoes and retaining springs from the transmission. Remove the actuating lever, shoe retaining springs, and then remove the shoes.
4. On Transmatic Drive, pry the parking brake shoe lower retaining spring from the shoes. Remove the bolts and lockwashers attaching the carrier plate to the transmission. **Do not remove the bolt that attaches the spline flange to the output shaft.**
5. With one hand on the actuating lever, slide the carrier plate away from the transmission housing and, at the same time, remove the actuating lever. Rotate the carrier plate and shoes as an assembly approximately 180 degrees, disconnect the brake shoe upper retaining springs, and remove the shoes.

Installation

If the brakes require relining, see Part 12-01 for relining procedures.

1. On all transmissions except Transmatic Drive, install the brake shoe lower retaining spring on the shoes. Position the shoes and lower retaining spring on the back side of the carrier plate, install the shoe upper retaining springs and the actuating lever. Place the assembly on the transmission and install the attaching bolts. Install the transmission spline flange.
2. On Transmatic Drive, position the brake shoe lower retaining spring in place. Lift the two shoes and spring as an assembly and place on the top back side of the carrier plate. The spring should be on the transmission side of the shoes. The carrier plate is still 180 degrees out of its normal position to facilitate the installation of the shoe upper retaining springs.
3. Install the brake shoe upper retaining springs. Rotate the carrier plate 180 degrees, position the actuating lever in the ball socket and push the carrier plate toward the transmission. **Be sure the ends of the actuating lever are properly seated. Install the lockwashers and bolts to attach the carrier plate to the transmission housing.**
4. Install the brake drum and the drive shaft.
5. Connect the actuating lever to the parking brake linkage. Check the brake operation and adjust the linkage as necessary.

PART 12-81 Parking Brake — Internal Shoe, Transfer Case Mounted

FIG. 1 Transfer Case Controls and Linkage

ADJUSTMENT

BRAKE LINKAGE ADJUSTMENT

1. Place the parking brake lever in its fully OFF position.
2. Disconnect the adjusting rod clevis at the bellcrank (Fig. 1).
3. Push the parking brake bellcrank toward the clevis to remove the free play from the parking brake shoe operating lever.
4. Adjust the adjusting rod length so that it can be positioned on the bellcrank. Install the clevis pivot pin, washers and cotter pin.
5. Tighten the adjusting rod jam nut.

REMOVAL AND INSTALLATION

DRUM, SHOES AND BACKING PLATE

Removal

1. Release the parking brake floor lever.
2. Disconnect the parking brake rod from the brake shoe operating lever.
3. Cut the lock wire and remove the capscrews retaining the brake drum to the brake flange. Remove the drum.
4. Remove the brake hub retaining snap ring (Fig. 2).
5. Using a suitable puller, remove the brake hub from the front output shaft gear (Fig. 3).
6. Unhook the brake shoe return springs and remove the brake shoes and lever (Fig. 4).
7. Remove the mounting bolts and lift off the brake backing plate, washer, deflector and gasket (Fig. 5).

Installation

1. Position a new gasket to the case and then mount the brake backing plate, deflector and stamped washer. Insert the cap screws with star washers and tighten to 60-77 ft-lbs.
2. Position the brake lever on the backing plate.
3. Position the brake shoes on the backing plate with actuating pawl in the web slot.
4. Install brake shoe return spring.
5. Slide the brake hub over the splines of the front output gear. Install the retaining ring.
6. Install the brake drum with lockwashers and cap screws. Torque the cap screws to 60-77 ft-lbs and insert lock wire.
7. Install the expansion plugs. The smaller plug goes in the bore or the front output gear and the larger in the brake hub.
8. Connect the parking brake rod to the shoe operating lever and adjust linkage as necessary.

PART 12-83 Parking Brake — Maxibrake — Rear Wheels, Air

Applies To 600 Thru 900 Series Trucks with Cam Type Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CHAMBER		DESCRIPTION	83-01
Disassembly and Assembly	83-02	PARKING BRAKE (MANUAL RELEASE)	
Removal and Installation	83-02	Adjustment	83-02

DESCRIPTION

AIR CHAMBER

On vehicles equipped with full air brakes of the S-cam type, a Maxibrake emergency stop safety feature is available.

The Maxibrake air brake chamber (used on the rear axle only) is much like the conventional brake chamber, and differs only in that it contains an independently operated spring loaded piston which, when released due to low air pressure, will set the service brakes (Fig. 1).

A manual control valve located in the cab exhausts the air from the safety chamber for safety stops, or to set the service brakes for parking.

SCHRADER VALVE

The air system on all vehicles with spring actuated rear wheel parking brakes is equipped with a Schrader valve for connection to an outside air supply. This valve permits the system to be recharged with air from an outside source, releasing the spring actuated parking brakes. The vehicle may then be towed in an emergency. **Outside air source can be used only if protected system is in operating condition.**

Schrader Valve Location

The Schrader valve is located on the protected air tank on F-, B-, and C-Series vehicles. On W-and WT-Series trucks, the Schrader valve is located on the air manifold under the right front side of the cab (just above right headlamp). All L-Series have the Schrader valve located on the outboard side of the left side air tank.

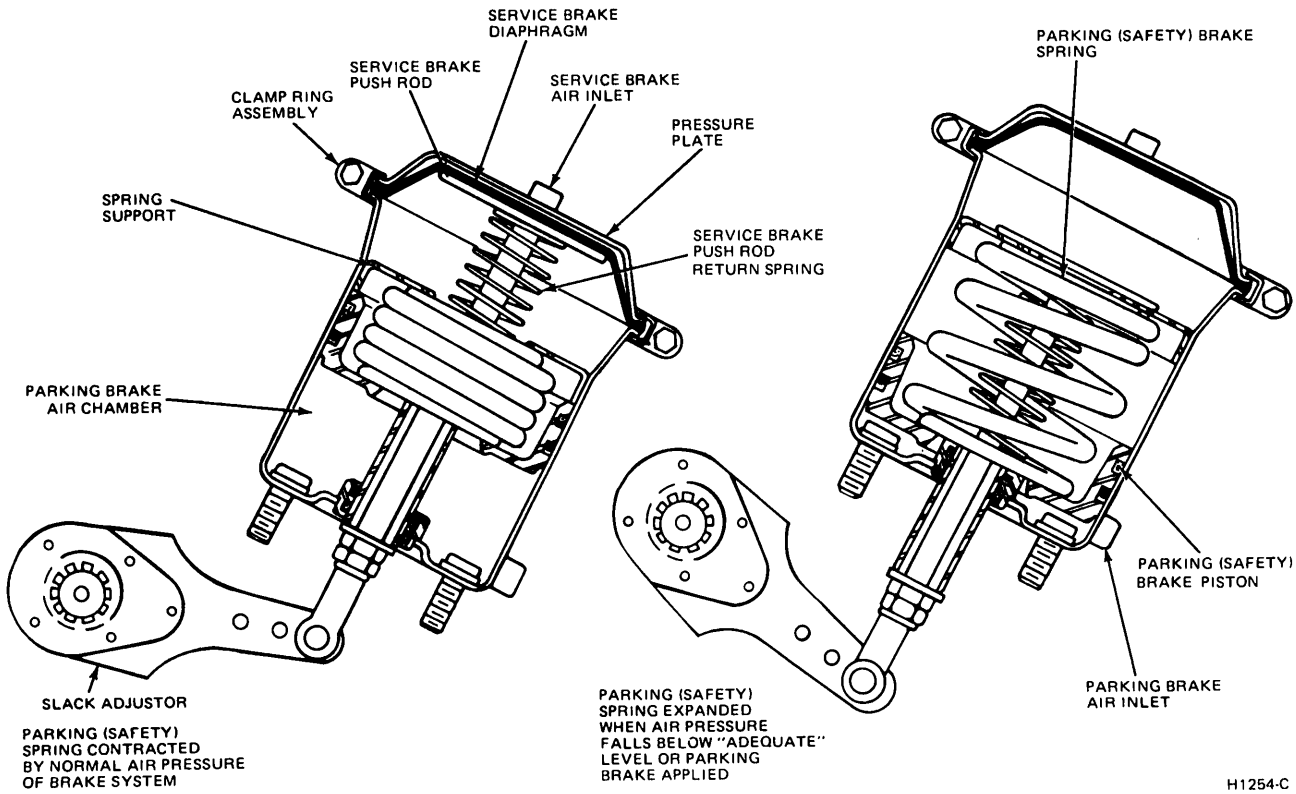

FIG. 1 Maxibrake Operation

ADJUSTMENT

SLACK ADJUSTER

Refer to Part 12-40 for slack adjuster adjustment.

MAXIBRAKE MANUAL RELEASE

If air pressure cannot be restored in the protected air system, the spring actuated brakes must be released as follows:

1. Disconnect air hoses from spring brake port of the chamber.
2. Install Schrader valves in chambers.
3. Charge the chambers with air from an outside source.
4. Remove the Schrader valves (after normal air pressure has been restored) and reconnect all lines.

REMOVAL AND INSTALLATION

AIR CHAMBER ASSEMBLY

Removal

1. Release all the air from the system, and then disconnect the air lines from the brake chamber.
2. Install a Schrader valve in the parking (spring) brake air chamber and charge the chamber with approximately 100 lbs. This will hold the parking brake spring compressed.
3. Disconnect the push rod yoke from the slack adjuster.
4. Remove the mounting nuts and remove the brake chamber.

Installation

1. Position the brake chamber assembly on the mounting bracket and install the attaching nuts. Torque the nuts to 110-150 ft-lbs.
2. Connect the push rod yoke to the slack adjuster.
3. Carefully release air from the parking brake chamber by means of the Schrader valve. Then, remove the Schrader valve. Connect the air lines to the brake chamber and build up the air pressure.
4. Adjust the brakes.

SERVICE BRAKE DIAPHRAGM

If a new diaphragm is installed in the brake chamber on one side of the axle, a new one should be installed in the corresponding brake chamber on the opposide side also; otherwise uneven braking may result.

Removal and Installation

1. Scribe the pressure plate, clamp ring and cylinder assembly to aid in reassembly.
2. Remove the clamp ring and pressure plate.
3. Remove the service brake diaphragm.
4. Place the service brake diaphragm on the pressure plate.
5. Position the pressure plate and diaphragm assembly on the cylinder assembly with the scribed marks in alignment.
6. Install the clamp ring so that the scribed marks are aligned and torque clamp ring bolts to 150-175 in-lbs.

DISASSEMBLY AND ASSEMBLY

SERVICE AND PARKING BRAKE CHAMBERS

Refer to Figure 2 for disassembled view.

Disassembly

1. Scribe the clamp ring, pressure plate and cylinder assembly so that they can be reassembled in the same position.
2. Mount the cylinder assembly in a vise, using one of the mounting studs with its nut or in a fixture such as shown in Figure 3.
3. Remove the clamp ring, pressure plate and service brake diaphragm (Figs. 4 and 5).
4. Remove the clevis yoke. Push inward on the service brake. Push rod face plate and remove the flanged nut from the push rod.
5. Remove the push rod assembly (push rod, spring retainer and return spring) as shown in Figure 5.
6. Free the push rod bushing from the cylinder boss using Tool T71T-2225-A inserted through the neck of the piston as shown in Fig. 6. Remove the bushing.
7. Install Tool T71T-2225-A through the cylinder assembly and loosely install spacer and nut as shown in Figure 7. This tool is used as a draw bar in order to safely release parking brake spring tension.
8. Tighten the nut on the tool shaft until the flat of the tool is centered and resting **firmly** against the parking brake spring support. This forces the spring to remain safely caged and permits the removal of the piston, spring support and spring assembly from the cylinder.
9. Remove the eight capscrews which hold the spring support in place (Fig. 8).
10. **Slowly** back off the nut on Tool T71T-2225-A until **all** spring pressure is released. Remove the tool and remove the parking brake spring support and the spring from the cylinder assembly.
11. Blow any loose dirt out of the cylinder with compressed air and wipe the cylinder walls clean. Using a drift the same outside diameter as the parking brake piston neck, or a socket of suitable size, drive the parking brake piston assembly out of the cylinder (Fig. 9).
12. Remove the wiper ring and the O-ring from the piston grooves (Fig. 10).

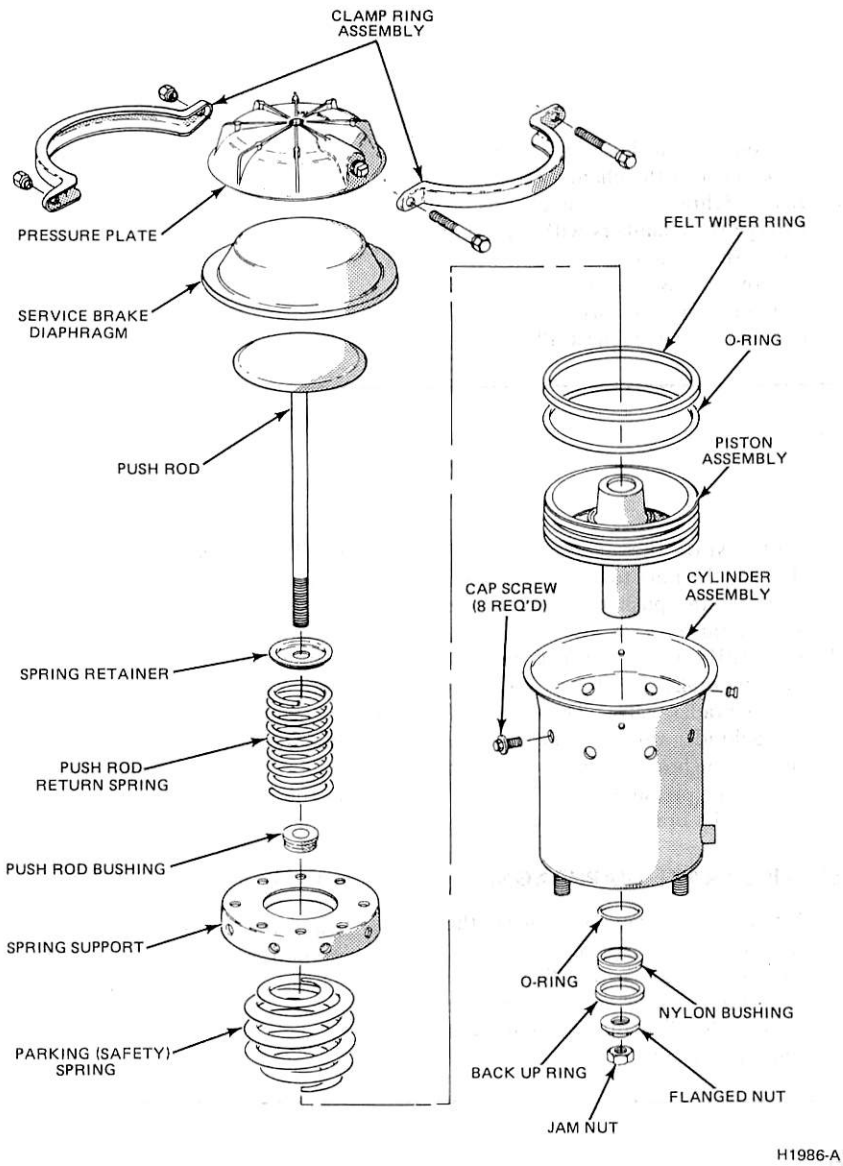

FIG. 2 Maxibrake—Disassembled View

13. Remove the O-ring, nylon bushing and back-up ring from the cylinder center boss. Use a sharp pointed instrument to remove the bushing; work clockwise from the cut to pry the bushing out of its groove; then remove the back-up ring.
14. Wash all metal parts in cleaning solvent. Inspect all parts for excessive wear or deterioration. Replace all seals and parts included in the seal kit.

Assembly

1. Coat the inside center boss groove with Lubriplate. Fill the piston O-ring groove (groove nearest neck) about half full of Lubriplate or equivalent. Lightly grease the inside of the cylinder wall with Lubriplate, or equivalent. Coat the safety piston spring with a rust inhibitor compound.
2. Install the back-up ring in the cylinder boss groove; then, the nylon bushing. **The bushing must be installed so that the side with a bevel edge faces towards the inside of the cylinder.**
3. Install the large O-ring in the bottom groove of the piston (groove nearest neck) and the saturated felt wiper in the top groove.
4. Insert the piston assembly into the cylinder, holding the felt wiper in place. Use a block of wood and a light hammer if necessary, to bottom

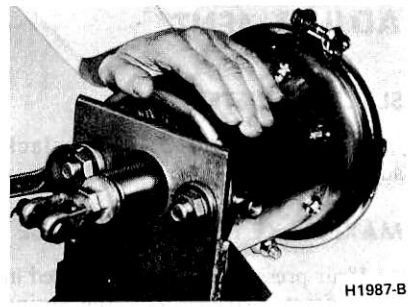

FIG. 3 Cylinder Assembly Mounted in Holding Fixture

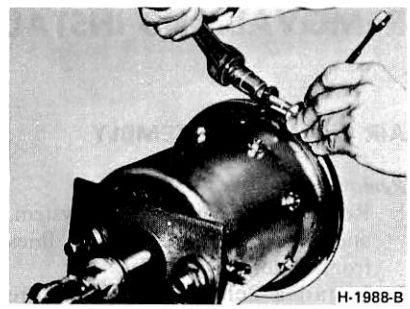

FIG. 4 Removing Clamp Ring Retaining Bolts

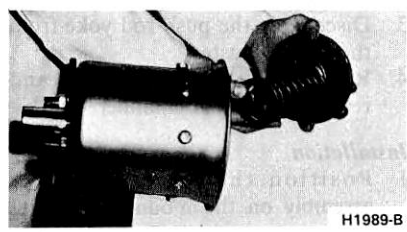

FIG. 5 Removing Push Rod Assembly

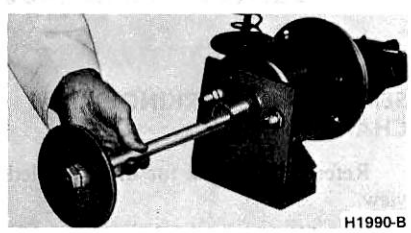

FIG. 6 Removing Push Rod Bushing

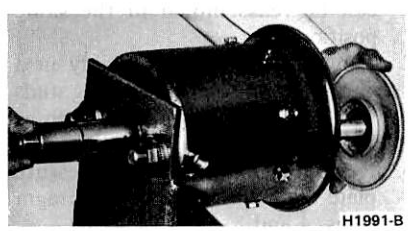

FIG. 7 Installing Tool T71T-2225-A

the piston assembly in the cylinder.

5. Place the safety piston spring on the piston in the cylinder. Place the safety piston spring support on the spring and install the draw bar Tool T71T-2225-A as shown in Figure 11.
6. Tighten the nut slightly while centering the spring over the piston hub and the spring support; then, tighten the nut, drawing the safety spring and the spring support into the cylinder until the holes in the spring support and the cylinder are in alignment.
7. Install the eight capscrews which secure the spring support to the cylinder (Fig. 12). Alternately tighten the capscrews.
8. Remove the draw bar tool.
9. Install the push rod bushing into the piston. Tap the bushing lightly to be sure that it is properly seated (Fig. 13).
10. Assemble the push rod spring retainer and the push rod return spring on the push rod and install the push rod and spring assembly in the cylinder. Secure the push rod with the flanged nut (Fig. 14).
11. Place the service brake diaphragm on the pressure plate (crown surface toward the pressure plate).
12. Position the pressure plate and diaphragm assembly on the cylinder assembly with the scribed marks in alignment. Apply hand pressure to the top of the pressure plate to compress the service piston return spring and install the clamp ring. Torque the clamp ring bolts to 150-175 in-lbs.
13. Install a Schrader valve in the safety chamber air inlet and charge the safety chamber with enough air to retract the safety piston (compressing the safety piston spring).
14. Screw the flanged nut on the push rod shaft until there is 1/16 inch space between the flange of the nut and the neck of the safety piston tube (Fig. 15). Lock the flanged nut in place with the jam nut.
15. Install the clevis yoke on the push rod. **Maintain a distance of 2 15/16 inches (plus or minus 1/8 inch) between the centerline of the clevis pin holes and the mounting flats of the cylinder assembly for Type 24 or 30 brake assemblies. This distance should be 3 1/4 inches (plus or minus 1/8 inch) for Type 36 units.**
16. After checking for air leaks, carefully release the air by depressing the Schrader valve; then, remove the Schrader valve.

Maximum permissible air leakage is 1 lb per minute at 100 psi test pressure.

SERVICE BRAKE DIAPHRAGM		Installation	84-04
Removal and Installation	84-03	Removal	84-04

DESCRIPTION AND OPERATION

BRAKE ASSEMBLY

The MGM Stopgard double diaphragm brake chamber assembly is used as a rear wheel service brake chamber, a spring applied parking brake and an emergency brake in case of air pressure loss (Figs. 1 and 2). This assembly is used with S-cam brakes only.

The brake chamber assembly consists of two separate air chambers each having its own application and release mechanism. The difference between the two chambers is that the service chamber applies the brake by air pressure and releases it by spring pressure. The spring brake chamber applies the brake by spring pressure and releases it by air pressure.

During normal driving (brakes released), the service brakes are held released by the diaphragm return spring in the service air chamber assembly. Air reservoir pressure against the spring brake chamber piston and diaphragm holds the parking emergency spring compressed.

During normal braking (service brakes applied) air pressure from the brake valve working against the service brake diaphragm applies the brakes. Air reservoir pressure in the spring brake chamber holds the parking-emergency spring compressed. Normal service brake operation is not affected by the spring brake.

During parking or an emergency

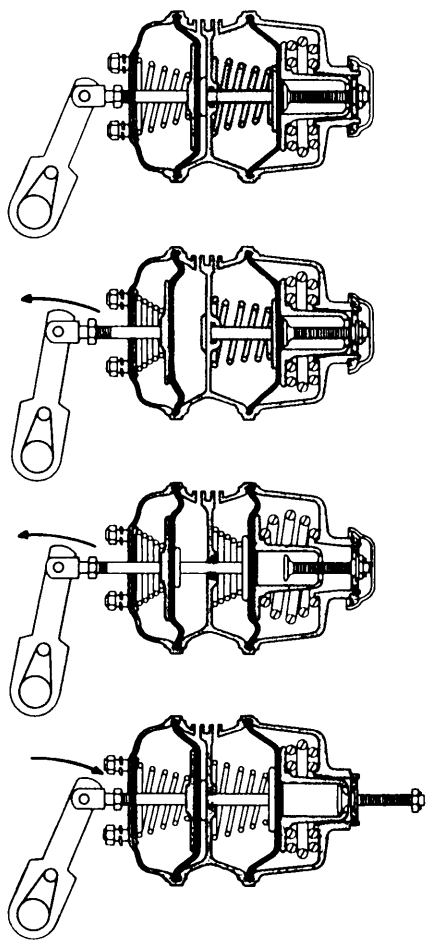

FIG. 1 MGM Stopgard Brake Operation

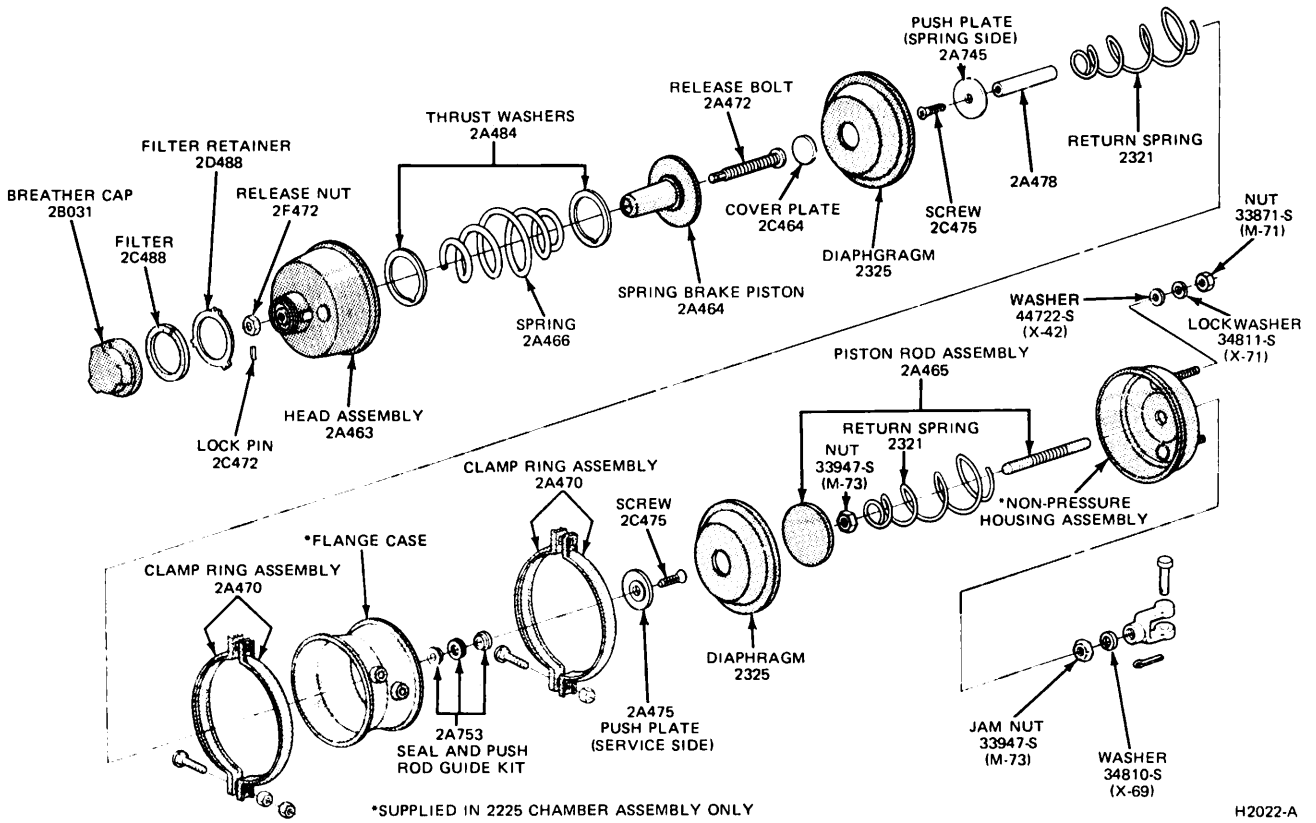

FIG. 2 MGM Stopgard Brake—Disassembled View

brake application, air is exhausted from the spring brake chamber. This permits the parking-emergency spring to expand, moving the spring brake piston and the service brake push rod against the slack adjuster assembly to apply the brakes.

Loss of system air pressure at the spring brake chamber will result in automatic application of the brakes. In the event it is necessary to move the vehicle before air pressure can be restored, the parking-emergency spring must be manually compressed. The procedure for manually releasing and then resetting the spring brake after repairs have been performed follows. **Do not drive vehicle until the air system is repaired.**

PARKING BRAKE AIR RELEASE

The air system on all vehicles with spring actuated rear wheel parking brakes is equipped with a Schrader valve for connection to an outside air supply. This valve permits the system to be recharged with air from an outside source, releasing the spring actuated parking brakes. The vehicle may then be towed in an emergency.

An outside air source can be used only if protected system is in operating condition.

A Schrader valve is located on the outboard side of the left side air tank for L-Series, on the protected air tank on C-Series and on the air manifold under the right front side of the cab (just above the right headlight) on the WWT-Series. If an auxiliary air source is not available and normal air pressure cannot be restored, the parking brake must be manually released.

PARKING BRAKE MANUAL RELEASE AND RESETTING

1. TO RELEASE: Block the wheels to prevent the vehicle from moving.
2. Remove (unscrew) the breather cap.
3. Using a 15/16 inch wrench, unscrew the release bolt (Fig. 3) approximately 30 turns until the brake shoes release from the drum. If the release bolt binds, apply rust penetrant (COAZ-19A501-A) or equivalent and allow it to soak into the threads.
4. TO RESET: If the release bolt threads are dry, coat the bolt with chassis lubricant. Screw the release bolt down into the unit until the nut bottoms against the case. Torque the nut to 50 ft-lbs.

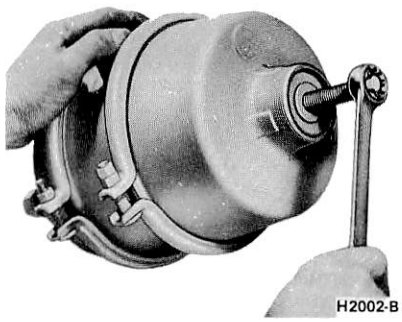

FIG. 3 Parking Brake Manual Release

REMOVAL AND INSTALLATION

COMPLETE UNIT

Removal

1. Exhaust all air from the system.
2. Disconnect all air lines from the brake air chambers.
3. **Follow manual release instructions.**
4. Remove the cotter pin from the clevis yoke pin and remove the clevis yoke pin.
5. Using a 15/16 inch wrench, remove the mounting stud nuts and lock washers. Remove the actuating unit.

Installation

1. Position the assembly on its mounting bracket.
2. Using a 15/16 inch wrench, install the two retaining bolts and lock washers. Torque the nuts to 150 ft-lbs.
3. Position the push rod yoke to the slack adjuster, insert the clevis yoke pin and install the cotter pin.
4. Tighten the push rod yoke lock nut.
5. Reset the parking brake as described under Parking Brake Manual Release and Resetting.
6. Connect the air lines to the brake air chambers. Charge the system and check for air leaks and proper operation. Refer to Part 12-40 and check adjustment of push rod travel.

SERVICE BRAKE DIAPHRAGM

Removal

1. **Follow Manual Release procedure.**
2. Exhaust all air from the system and disconnect the air lines from the brake chambers.
3. Holding the spring brake chamber with one hand, loosen the clamp ring retaining bolt nuts on the service brake chamber (Fig. 4).
4. Remove the clamp ring and lift the spring brake chamber away from the service brake chamber.
5. Remove the service brake diaphragm.
6. Inspect the diaphragm, return spring, service piston and the inside of the exposed chambers. Replace any worn or damaged parts.

Installation

1. Position the diaphragm over the service piston and return spring while checking alignment of the return spring to the chamber and piston.
2. Position the spring brake chamber on the diaphragm in the position as it was removed. Hold the two units together while installing the clamp ring.
3. Tighten the clamp nuts to 25-35 ft-lbs torque. Check all around the clamp ring to further insure proper actuator alignment and clamp seating. Using a soft hammer, tap the circumference of the clamp ring to further insure proper seating and retorque the clamp nuts to 25-35 ft-lbs.
4. Manually reset the parking (spring) brake (step 4 under Parking Brake Manual Release and Resetting).
5. Connect both air lines; then, operate both the spring brake and parking brake several times to insure proper operation.
6. With both brake chambers pressurized, soap test the clamp ring area to verify leak-free assembly; then, exhaust pressure in the service brake only and recheck torque on the clamp ring nuts.

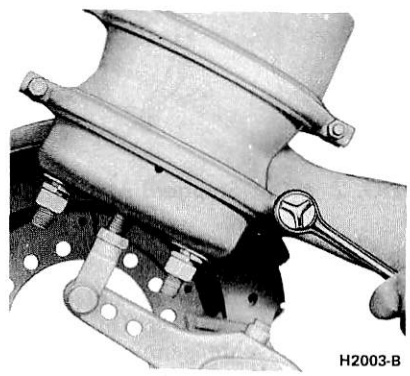

FIG. 4 Removing Service Brake Clamp Ring Retaining Bolt Nuts

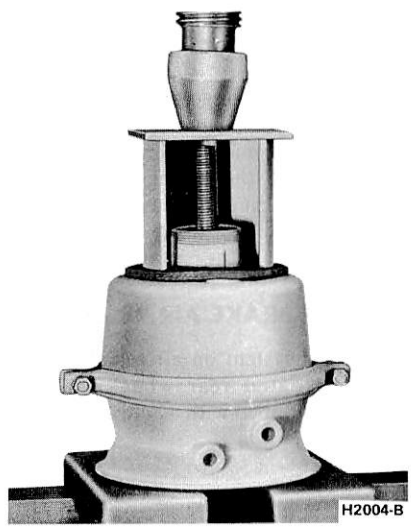

FIG. 5 Spring Brake Unit Positioned on Press

SPRING (PARKING) BRAKE DIAPHRAGM

Removal

1. Follow instructions (steps 1 through 4) under **Service Brake Diaphragm Removal. Be sure that the parking brake is manually released.**
2. Place the spring brake unit in a hydraulic press, using a slit tube and flat plate as shown in Figure 5. The slit tube can be fabricated locally using a 5 inch length of heavy 4 inch outside diameter pipe. The press ram must have a minimum of 8 inches of travel available **after** it has contacted the flat plate.
3. Take up very light pressure by the ram on the flat plate. Leave the press ram in this position and remove the clamp ring nuts (Fig. 6) and the clamp ring.
4. **Very slowly** release pressure on the press ram. At this point, there should be no outward pressure from within the actuator and the ram and plate should separate almost at once. **However, if tension remains between the press ram and the plate, either the unit is not fully manually released, or damage has occurred in the release mechanism. If the unit is released, but pressure is present, continue to relax the press slowly until the parking brake spring is fully extended and all parts are free.**
5. Lift off the head-spring-piston sub-assembly (Fig. 7). **Treat this sub-assembly with caution as the powerful parking brake spring is caged between the piston and head.**
6. Remove the parking brake diaphragm (Fig. 8). While the diaphragm is removed, inspect the inside of the flange case, return spring, push rod plate, screw and guide rings. (If service is required on any of these parts, refer to Parking (Spring) Brake Air Chamber and Spring Disassembly and Assembly). **Be sure that the screw holding the push rod plate to the push rod is very securely tight (Fig. 9).** Clean all exposed parts.

Installation

1. Check alignment of the return spring, position the diaphragm on the flange case, and place the parking brake spring and piston sub-assembly over the diaphragm (Fig. 7). Check for straight alignment of all parts and place the unit in a press with the split tube and flat plate in position on the case (Fig. 6).
2. Apply very light pressure to the plate with the press ram and reinstall the clamp ring (Fig. 6). Tighten the clamp ring nuts to 25-35 ft-lbs torque, and using a soft hammer, tap the circumference of the clamp ring to further insure proper seating. Retorque the clamp ring nuts to 25-35 ft-lbs.
3. With the assembly still in the press, attach a shop air line with 100-125 psi pressure to the spring brake inlet (Fig. 10). If a leak is discovered, disassemble unit, reposition parts and reassemble. If a leak still exists, change diaphragm. After passing the leak test, retighten the clamp ring nuts to 25-35 ft-lbs. torque. Also, install the second nut on each clamp ring bolt to form a secure lock.
4. Install the spring brake chamber assembly on the vehicle following the instructions under Service Brake Diaphragm Installation.

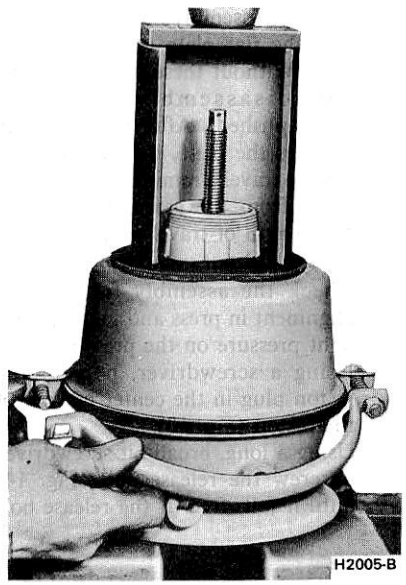

FIG. 6 Removing Spring Brake Chamber Clamp Ring

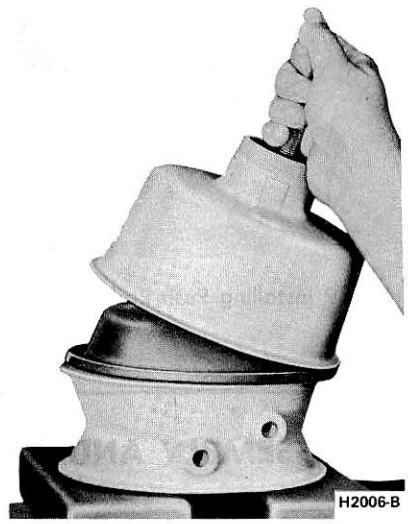

FIG. 7 Removing Parking (Spring) Brake Sub-Assembly

FIG. 8 Removing Parking (Spring) Brake Diaphragm

FIG. 9 Installing Push Rod Plate

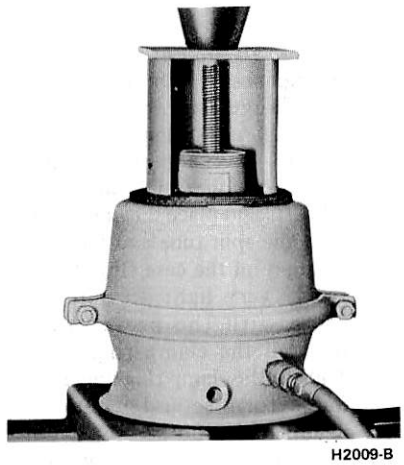

FIG. 10 Testing Spring Brake Diaphragm for Leaks

DISASSEMBLY AND ASSEMBLY

SPRING (PARKING) BRAKE AIR CHAMBER

Disassembly

1. Remove the spring brake section from the vehicle as described in steps 1 through 4 under Service Brake Diaphragm Removal.

If a broken power spring is suspected, confirmation can usually be made by screwing the release bolt **all the way into** the unit and vigorously shaking the assembly. Noticeable rattling from within the head end of the assembly normally confirms a fractured spring. Further evidence would be supplied by only light resistance when screwing the release hold down.

Even though a broken spring may have been confirmed, it is important to manually release the actuator again before further disassembly.

2. Remove the lock pin from the release bolt, using a 1/8 inch diameter punch (Fig. 11).
3. Remove the head-spring-piston sub-assembly from the flange case by following step 2 through step 5 of Spring (Parking) Brake Diaphragm Removal.
4. Position the head-spring-piston assembly in a press as shown in Figure 12. (It is important to position one 4 inch diameter, approximately 3-4 inch length slit-tube under the assembly supporting the piston and another 4 inch diameter, 4-6 inch length slit tube over the assembly between the head and the flat plate under the press ram. Without these tubes, the final **safe** disassembly cannot be accomplished). After the press ram touches the plate, the ram must be able to travel a minimum of 8 inches away from the assembly. Without this length of travel available, the spring will not completely relax.
5. Check the assembly for straight alignment in press and take up very light pressure on the press ram.
6. Using a screwdriver, pop off the piston plug in the center bottom of the piston (Fig. 13).
7. Using a long, broad-bit screwdriver unscrew the release bolt (Fig. 14) until it falls free. If the release bolt resists removal, take up slightly more pressure on ram.
8. With release bolt removed, **gradually** relax the ram (Fig. 15) until head loses contact with press ram (Fig. 16).
9. After disassembly all parts should be thoroughly washed in clean solvent and visually inspected for wear and/or damage. Replace any parts as required.

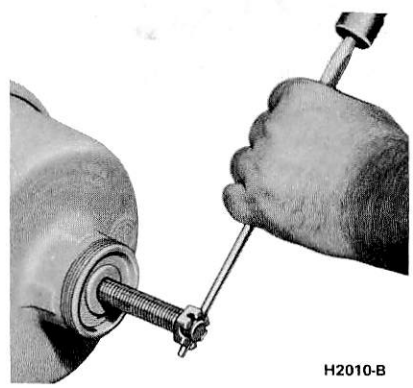

FIG. 11 Removing Lock Pin from Release Bolt

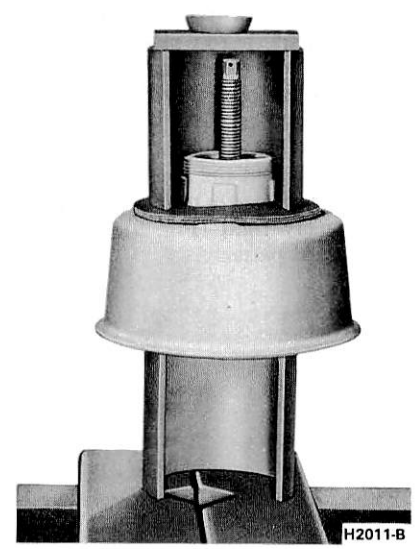

FIG. 12 Spring Brake Sub-Assembly Positioned in Press

Assembly

1. Prior to reassembly of the head-spring-piston sub-assembly, generously apply Chassis Lubricant (COAZ-19A501-A) to the inside of the head centerwell, the outside of the piston shank, the inside of the piston shank, and to the release bolt.
2. Place the slit-tube on the press base and position the parts on top in the following order: piston thrust washer (late models use a spring shield cup in place of this thrust washer), spring, thrust washer, and head—followed by the second slit-tube and the flat plate (Fig. 17).
3. Check straight up-and-down alignment of all parts and **standing to the side of the press,** take up tension very slowly on the press ram (Fig. 15). **Check alignment continually as straight-in reassembly is important.** If misalignment occurs, relax press and begin compression of spring again.
4. With the spring completely compressed between the piston and head and with the piston bottomed up inside the head, replace the release bolt up through the piston shank (Fig. 14).
5. Screw the bolt in until approximately 3 inches of the bolt extends through the head insert (Fig. 12).
6. Relax tension on the press ram slowly until the parts separate from the ram.
7. Remove the sub-assembly from the press and replace the release nut on the release bolt. Lock it in place with the lock pin (Fig. 1).
8. Replace the piston plug in the center hole of the piston. Firmly tap the center of the plug with a hammer so that it moves over-center to a flat position (Fig. 18).

FLANGE CASE

Disassembly

1. Follow step 1 through step 5 of Spring (Parking) Brake Diaphragm Removal.
2. With left hand holding the large push rod plate (Fig. 6), remove the screw holding the plate to the push rod. If the screw resists removal, it may be necessary to use a pair of padded pliers to securely hold the push rod from turning (Fig. 19). Use caution when finally unscrewing the screw for the push rod plate retains the return spring under light tension.
3. Remove all parts from the flange case and wash them thoroughly.
4. Remove the guide rings (Fig. 20) and the push rod seal. This seal can best be removed by inserting a small bladed screwdriver behind the seal in the groove (Fig. 21) and very carefully prying the seal out of the groove.

Assembly

1. Clean the seal groove in the case, lightly lubricate groove, lubricate a new push rod seal, and reinsert the seal into the groove carefully so as not to damage it. Seat the seal in the groove by running your finger around the inside diameter.
2. Replace the guide rings on both sides of the seal (Fig. 20). The widest flange side always faces away from the seal.

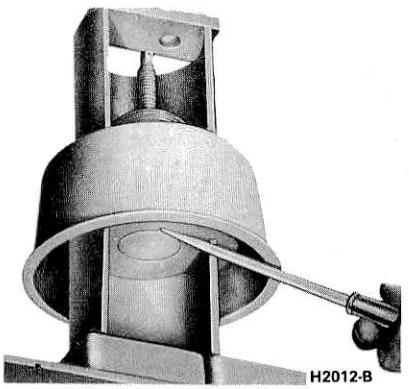

FIG. 13 Removing Piston Plug

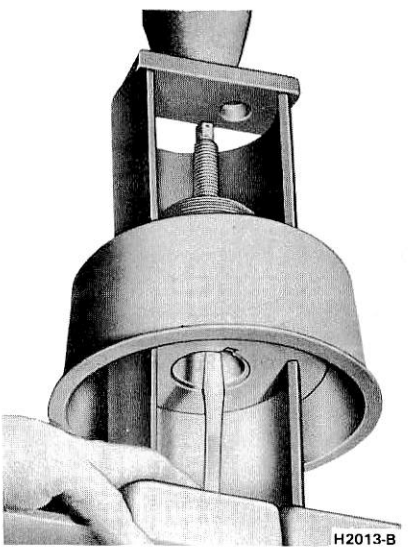

FIG. 14 Removing Release Bolt

3. Install the smaller push rod plate back on the push rod if it was removed and **securely** lock it with the screw. Take care not to mark or damage the surface of the push rod. Lubricate the tip of the push rod and insert it through the seal from the service brake side of the case.
4. Place the case and push rod sub-assembly on any 3 inch diameter support on a work bench. Install the return spring in the case and compress the spring enough with the large push rod plate to be able to reinstall the screw through the plate and into the push rod.

The screws holding the two plates to the push rod must be very securely tight. To properly tighten both screws, grip outside diameter of the bottom plate with a smooth-jaw vise and securely tighten the screw holding the upper, largeplate. This will tighten both screws at the same time.

5. Check alignment of the return spring in the flange case and to the large push rod— straightness is important (Fig. 22).
6. Inspect the diaphragm before further assembly and replace if worn, damaged, or over one (1) year old.
7. Follow step 1 through step 4 of Parking (Spring) Brake Diaphragm Installation to reassemble the flange case to the head-spring-piston sub-assembly.

PART 12-85 Parking Brake — MGM Shortstop — Rear Wheels, Air

Applies To 600 Thru 900 Series Trucks with Wedge Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CHAMBER		DESCRIPTION	85-01
Assembly	85-03	SHORTSTOP UNIT ONLY	
Disassembly	85-02	Manual Release	85-02
Removal and Installation	85-02	Removal and Installation	85-02

DESCRIPTION

MGM SHORTSTOP SYSTEM

The Shortstop parking and emergency brake system is available on trucks equipped with the Bendix Twinplex-wedge-type air brake.

Shortstop spring brake units provide mechanical spring actuation of the Twinplex wedge brakes whenever air pressure fails. During normal operation, the Shortstop power spring is held compressed by system air pressure under the piston in the unit (Fig. 1).

For parking operation, a control valve is provided in the cab. Pulling the valve knob out will release the air from the Shortstop pressure chamber, allowing the spring pressure to apply the brakes. The spring will be compressed again and the brakes released as soon as the parking valve is pushed in and/or system air pressure is restored by the compressor.

The air system on all vehicles with spring actuated rear wheel parking brakes is equipped with a Schrader valve for connection to an outside air supply. This valve permits the system to be recharged with air from an outside source, releasing the spring actuated parking brakes. The vehicle may then be towed in an emergency. An outside air source can be used only if protected system is in operating condition.

Schrader Valve Location

The Schrader valve is located on the protected air tank on F-, B-and C-Series vehicles. On W-and WT-Series trucks, the Schrader valve is located on the air manifold under the right front side of the cab (just above right headlamp). All L-Series have Schrader valve located on the outboard side of the left side air tank.

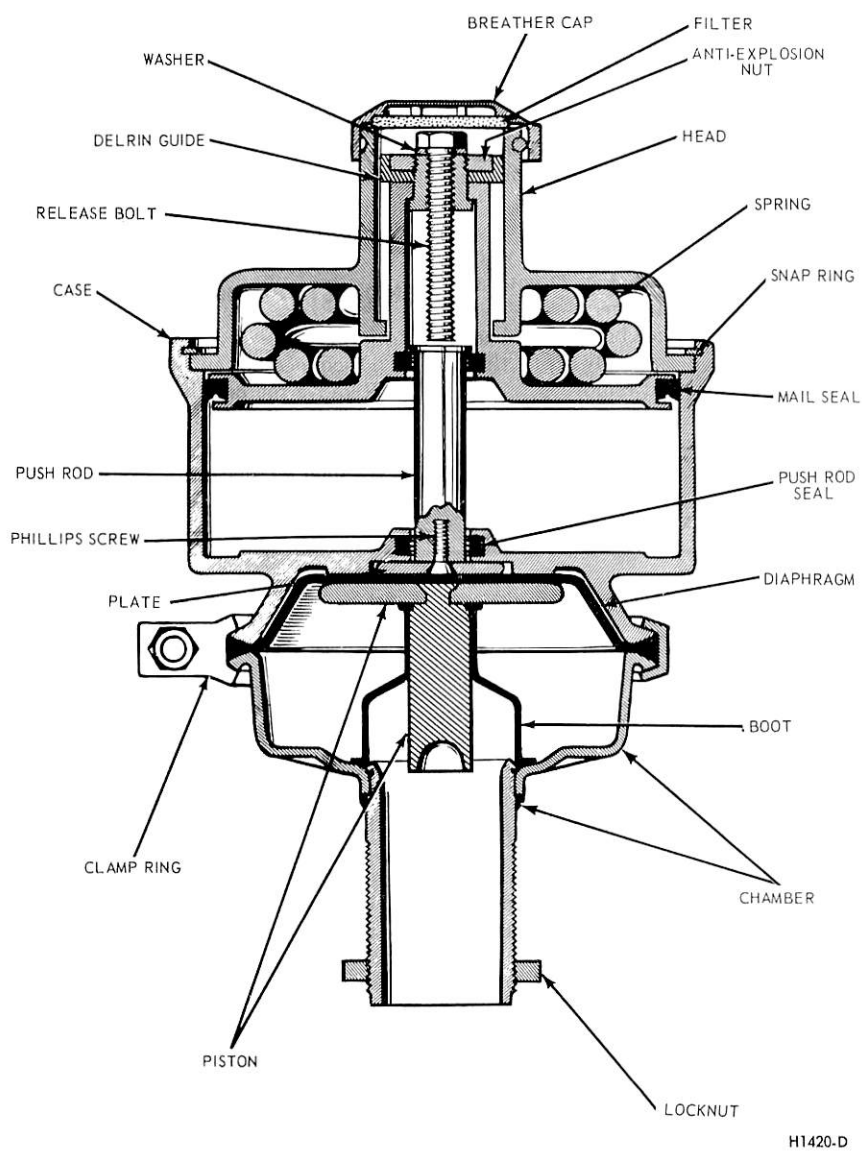

FIG. 1 MGM Shortstop Brake—Sectional View

ADJUSTMENTS

SPRING BRAKE MANUAL RELEASE

If air pressure fails in the Shortstop piston chamber, the power spring applies the brakes, and, unless pressure can be re-established, the service brakes must be released as follows in order to move the truck:

1. Remove the bolt and nut holding the cap and filter to the housing (Fig. 1), and remove the cap and filter.
2. Using a 9/16 inch deep socket wrench, unscrew the release bolt until it turns freely. The brake shoe pressure is now released. Follow this procedure until all Shortstop units are released.
3. When air pressure has been restored, screw the release bolt in until the lock washer holds it securely. This **MUST** be done to regain Shortstop protection.

REMOVAL AND INSTALLATION

COMPLETE UNIT

Removal

To remove the complete Shortstop unit from the brake assembly proceed as follows:

1. Disconnect all air lines to the unit.
2. Remove the breather cap and filter and unscrew the release bolt completely, using a deep-socket 9/16 inch wrench.
3. Loosen the lock nut on the service brake chamber tube (Fig. 1) with a drift punch and hammer.
4. Unscrew the service brake chamber and Shortstop assembly from the wedge housing and remove.

Installation

1. Be sure the release bolt is unscrewed completely.
2. Position the Shortstop unit and service brake chamber to the wedge housing and turn the unit into the housing until it bottoms.
3. Back the unit out less than one turn to align hose connections, and tighten the lock nut.
4. Connect the air lines, charge the Shortstop chamber with air and screw the release bolt in tight. Install the cap and filter.

SHORTSTOP UNIT ONLY

Removal

1. Disconnect all air lines to the unit.
2. Remove the breather cap and filter and unscrew the release bolt completely, using a deep-socket 9/16 inch wrench.
3. Remove the clamp ring fastening the Shortstop unit to the service brake chamber and remove the Shortstop unit.

Installation

1. Make sure the release bolt is completely unscrewed.
2. Position the Shortstop unit to the service brake chamber and install the clamp ring.
3. Connect the air lines, charge the Shortstop chamber with air and screw the release bolt in tight. Install the cap and filter.

OVERHAUL

Disassembly

1. With the unit removed from the vehicle, and using a sharp, thin-bladed penknife or screwdriver, remove the soft solder from the head of the Phillips screw shown in Figs. 1 and 2.
2. Position a Phillips head screwdriver to the screw and seat it in the screw slots with the aid of a light hammer.
3. Remove the Phillips head screw and the pressure plate (Figs. 1 and 2).
4. Remove the release bolt and the washer and insert a screwdriver through the release bolt hole. Hold the screwdriver firmly against the top of the push rod (Fig. 1) and charge the spring brake piston chamber with air (minimum 70 psi).
5. Remove the screwdriver and unscrew the anti-explosion nut and delrin guide washer, using a drift punch and hammer.
6. Exhaust the air pressure. Remove the sealant covering and assembly snap ring (Figs. 1 and 2) between the head and the case.

Place the spring brake assembly in an arbor press prior to final disassembly. Press must have 6 inch stroke remaining after unit is placed in the press.

7. Take up a slight tension on the press. Do not attempt to compress head into case.
8. Using a screwdriver, remove the snap ring from the groove in the case.
9. Relax the press slowly. The spring will push the head out of the case. **If the assembly has a broken spring, use a cage or screen for protection. When the spring is free, remove the whole assembly from the press.**
10. Remove the head and the spring from the case.
11. Grasp the piston by its hub and pull it straight out of the case.
12. Wash all parts in a suitable non-oily solvent.
13. Inspect all parts for wear or damage. Replace with new parts or refinish with emery or crocus cloth, if necessary.

Air Chamber Repair

1. Clean inside of the service brake chamber. If a new boot is required,

it should be cemented to the chamber tube and allowed to dry at least ten minutes (3M No. EC-2141 or EC-1357 Adhesive recommended).

2. Install the piston, making sure the wedge shaft fits into the piston seat.
3. If a new diaphragm is to be installed, cement the diaphragm to the piston and allow to dry at least ten minutes (3M No. EC-2141 or EC-1357 Adhesive recommended).
4. Install the clamp ring with the diaphragm between the service brake and spring brake chambers. Tighten the clamp ring bolt and nut. Tap the circumference of the ring with a soft hammer to seat the ring, and retighten the bolt and nut.
5. Connect the air lines, charge the spring brake with air and screw down the release bolt and washer.
6. Install the breaker cap and new polyurethane filter, securing them with the bolt and nut furnished. Actuate the spring brake several times to check operation. Actuate the service brake several times to check operation.

Assembly

Before assembly, check all parts to be sure they are perfectly clean. Then apply a low temperature moly-type lubricant to all inside surfaces.

1. Lightly lubricate the seal groove in the piston with a low temperature moly-type lubricant. Repeat the procedure for the collar seal and push rod seal (Figs. 1 and 2).
2. If removed from the piston, the push rod is installed by working the flanged end through the seal in the center of the piston.
3. Install the piston assembly in the case, starting the piston at a 45 degree angle. Slowly bring the piston hub up to 90 degrees and install the push rod in the seal.
4. Install the spring on the piston and the head on the spring.
5. Place the assembly in an arbor press and slowly compress the spring. Use care, making sure the piston hub enters the head opening correctly. Continue to compress the assembly, making sure the lip of the head seats against the shoulder of the case correctly.
6. Install the snap ring. Tap both ends of the snap ring to insure complete seating.
7. Relax the press pressure and remove the assembly from the press.
8. Using a screwdriver through the release bolt hole, press down firmly on the push rod while charging the cylinder with air (minimum 70 psi).
9. Remove the screwdriver and install the guide washer on the insert in the piston hub. Tighten the washer to 30 ft-lb. Make the following air leak tests:

Checking For Air Leaks

1. Charge the unit with air. Apply oil around the guide washer. If bubbles appear, replace the main seal.
2. Charge the unit with air. Apply oil around the push rod in the diaphragm end of the case. If bubbles appear, replace the push rod seal.
3. Install the pressure plate on the push rod. Use emery cloth to smooth burrs off the head of the Phillips head screw, if present.
4. Clean the snap ring groove area with solvent and apply a sealant to cover the snap ring (Fig. 1). If possible, allow the sealant to dry overnight before installing the unit on the truck.

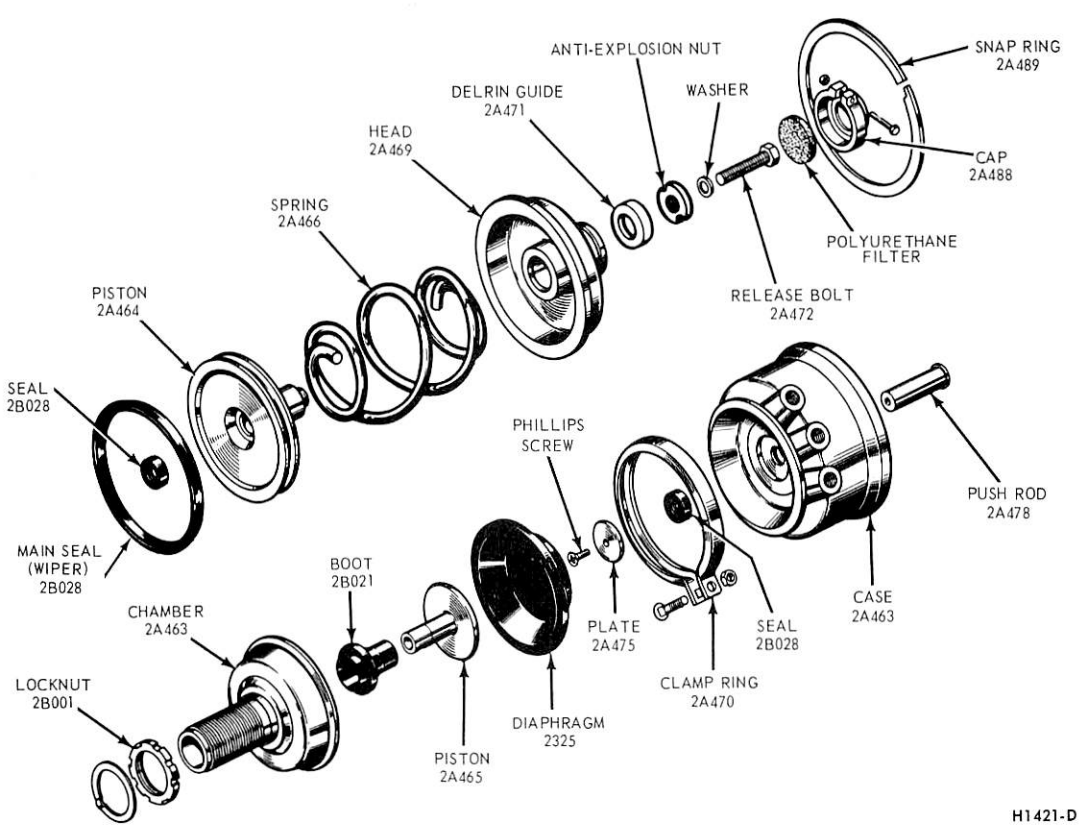

FIG. 2 MGM Shortstop Brake—Disassembled View

PART 12-86 Parking Brake — MGM Low Profile - Rear Wheels, Air

Applies to LT-Series with 30,000, 34,000 and 38,000 Lb. (34,000 Lb. Suspension) Axles and Wedge Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CHAMBERS		DESCRIPTION	86-01
Disassembly and Assembly	86-03		
Removal and Installation	86-03	PARKING BRAKE	
		Air Release	86-02
BREATHER (AIR) FILTER		Manual Release	86-02
Removal and Installation	86-03	Manual Resetting	86-02

DESCRIPTION AND OPERATION

The MGM Low Profile brake chamber assembly is used as a rear wheel service brake chamber, a spring applied parking brake and an emergency brake in case of air pressure loss (Fig. 1).

The brake chamber assembly consists of two separate air chambers each having its own application and release mechanism. The difference between the two chambers is that the diaphragm type service chamber applies the brake by air pressure and releases it by spring pressure. The piston type spring brake chamber applies the brake by spring pressure and releases it by air pressure.

During normal driving (brakes released), the service brakes are held released by the diaphragm return spring in the wedge assembly. Air reservoir pressure against the spring brake chamber piston holds the parking-emergency spring compressed.

During normal braking (service brakes applied) air pressure from the brake valve working against the service brake diaphragm applies the brakes. Air reservoir pressure in the spring brake chamber holds the parking-emergency spring compressed. Normal service brake operation is not affected by the spring brake.

During parking or an emergency brake application, air is exhausted from the spring brake chamber. This permits the parking-emergency spring to expand, moving the spring brake piston and the service brake push rod against the wedge assembly to apply the brakes.

Loss of system air pressure at the spring brake chamber will result in automatic application of the brakes. In the event it is necessary to move the vehicle before air pressure can be restored, the parking-emergency spring must be manually compressed. The procedure for manually releasing and then resetting the spring brake after repairs have been performed follows. **Do not drive vehicle until the air system is repaired.**

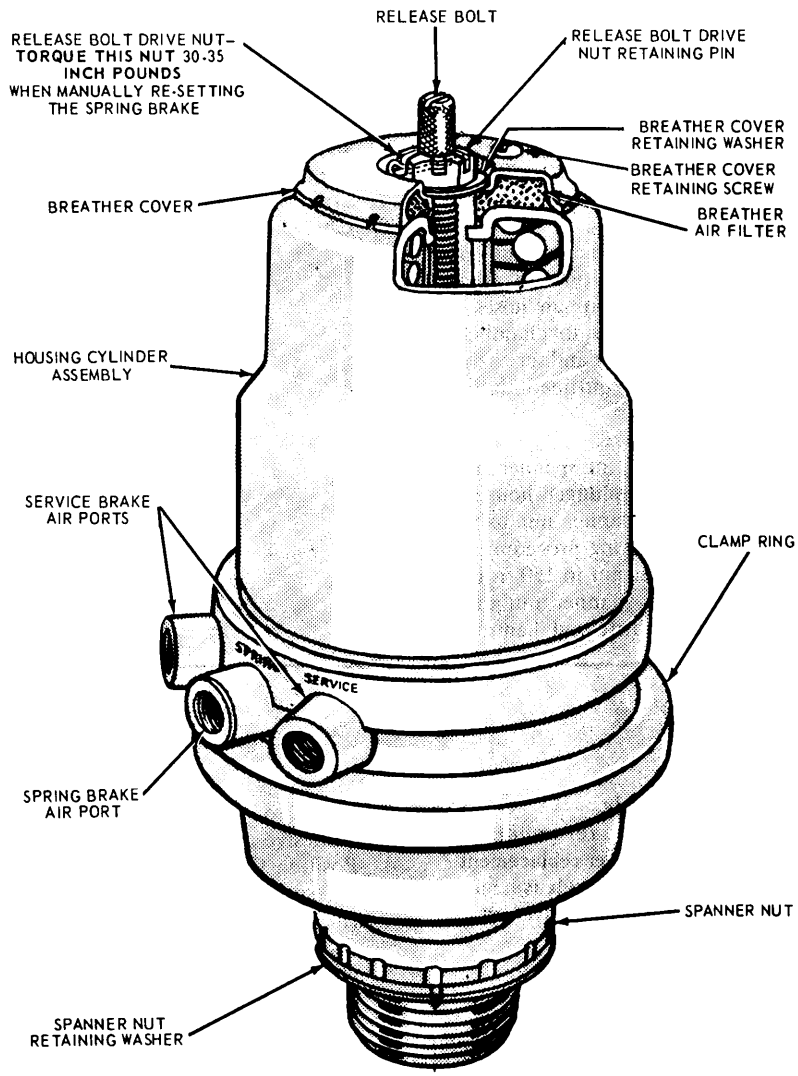

FIG. 1 MGM Low Profile Brake—Sectional View

ADJUSTMENTS

PARKING BRAKE AIR RELEASE

The air system on all vehicles with spring actuated rear wheel parking brakes is equipped with a Schrader valve for connection to an outside air supply. This valve permits the system to be recharged with air from an outside source, releasing the spring actuated parking brakes. The vehicle may then be towed in an emergency.

An outside air source can be used only if protected system is in operating condition.

A Schrader valve is located on the outboard side of the left side air tank. **If an auxiliary air source is not available and normal air pressure cannot be restored, the parking brake must be manually released.**

PARKING BRAKE MANUAL RELEASE

1. Block the wheels to prevent the vehicle from moving.
2. Using a 3/4 inch deep socket, unscrew the release bolt (Fig. 1) approximately 1 3/4 inches. **Do not use an air impact wrench since this will damage the assembly.**

PARKING BRAKE MANUAL RESETTING

1. If the breather cover and filter are loose, tighten the breather cover retaining screw.
2. Using a 3/4 inch deep socket, screw the release bolt until the nut securely butts the flat washer against the breather cover. **Torque the drive nut 30-35 in-lbs. Do not over torque the nut or use an air impact wrench since this will damage the assembly.**

REMOVAL AND INSTALLATION

AIR CHAMBERS

Removal

1. **Manually compress the parking-emergency spring** by unscrewing the release bolt as outlined under Manual Release.
2. Remove air hoses from the assembly **after exhausting system air pressure.**
3. Disengage the spanner nut retaining washer from the spanner nut, loosen the spanner nut and remove the assembly.

Installation

1. **Make sure the parking-emergency spring is compressed** and the spanner nut is screwed onto the chamber tube as far as it will go (to end of threads).
2. Install a new spanner nut washer with raised part of washer toward the plunger housing, and screw the assembly into the housing until it bottoms.
3. If necessary, back chamber out not more than one full turn to align chamber for connecting air hoses.
4. Connect all air lines to chamber, charge system with air and screw the release bolt in as outlined under Manual Resetting.
5. Apply parking brake.
6. Engage raised part of spanner nut washer in slot of plunger housing and tighten the spanner nut using either of the following procedures:
   a. Torque spanner nut to 150 ft-lbs.
   b. Hand tighten spanner nut and then using a drift and hammer advance (tighten) it 1 1/2 teeth.
7. Bend spanner nut washer into one of the nut slots and release the parking brake.
8. Check all connections for leaks.

OVERHAUL

The parking brake air chamber is serviced as an assembly only and should not be disassembled except for performing the following maintenace:

Replace or clean the breather (air) filter each 50,000 miles or one (1) year during on-highway operation and each 24,000 miles during off-highway operation. If cleaning is performed, use isopropyl alcohol and dry with compressed air. **Do not operate vehicle without a breather ccover or filter.**

Replace the service brake diaphragm each 50,000 miles or one (1) year.

BREATHER (AIR) FILTER

Removal and Installation

1. Build up system air pressure to governor cut-out to insure full compression of the parking-emergency spring.
2. Using a 3/4 inch deep socket, unscrew the release bolt (Fig. 1) approximately 1 inch.
3. Remove the breather cover retaining screw.
4. Remove the breather filter by carefully stretching it over the cover.
5. Reinstall a new or cleaned filter.
6. Position the cover on the top of the housing cylinder and install the cover retaining screw. Screw the release bolt in until the nut securely butts the flat washer against the cover. **Torque the nut 30-35 in-lbs. Do not over torque the nut or use an air impact wrench since this will damage the assembly.**

The filter and cover must be replaced if damaged. Cover replacement requires removal of the release bolt drive nut retaining pin and drive nut.

SERVICE AIR CHAMBER

Disassembly

1. Manually compress the parking-emergency spring by unscrewing the release bolt as described under Manual Release.
2. Scribe a locating mark on the spring brake, clamp ring and service air chambers to permit reassembly in the same position.
3. Remove the breather (air) filter.
4. Remove the clamp ring and separate the two chambers. **Do not attempt to disassemble the spring brake chamber.**
5. Remove the diaphragm, piston and piston boot from the service air chamber (Fig. 2).

Assembly

1. Clean inside of the service brake chamber. If a new boot is required, it should be cemented to the chamber tube and allowed to dry at least ten minutes (3M No. EC-2141 or EC-1357 Adhesive recommended).
2. Install the piston, making sure the wedge shaft fits into the piston seat.
3. If a new diaphragm is to be installed, cement the diaphragm to the piston and allow to dry at least ten minutes (3M No. EC-2141 or EC-1357 Adhesive recommended).
4. Position the service air chamber to the spring brake chamber aligning the scribe marks made before disassembly. Install the clamp ring with the diaphragm between the service brake and spring brake chambers. Tighten the clamp ring bolt and nut. Tap the circumference of the ring with a soft hammer to seat the ring, and retighten the bolt and nut.
5. Connect the air lines, charge the spring brake with air and screw down the release bolt and washer.
6. Install the breather cover and new polyurethane filter. Actuate the spring brake several times to check operation. Actuate the service brake several times to check operation.

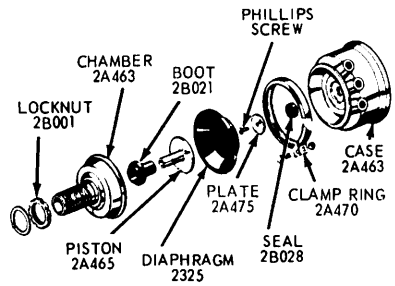

FIG. 2 MGM Low Profile Service Air Chamber—Disassembled

PART 12-87 Parking Brake — Anchor Lok — Rear Wheels, Air

Applies to C-, L-, W- and WT-Series with Cam-Type Brakes

COMPONENT INDEX	Page	COMPONENT INDEX	Page
AIR CHAMBER		DESCRIPTION	87-01
Disassembly and Assembly	87-02	PARKING BRAKE (MANUAL RELEASE)	
Removal and Installation	87-02	Adjustment	87-02

DESCRIPTION

The Anchorlok service and spring (parking) brake assembly is used on W-Series trucks with S-cam brakes.

The brake chamber assembly consists of two separate air chambers. Each chamber has its own diaphragm and push rod (Fig. 1). The service brake chamber applies the brake by air pressure and is released by spring pressure when air is exhausted. The parking or emergency brake is applied by spring pressure and is released by air pressure.

The diaphragms should be replaced every 50,000 miles or each year.

The air system on all vehicles with spring actuated rear wheel parking brakes is equipped with a Schrader valve for connection to an outside air supply. This valve permits the system to be recharged with air from an outside source, releasing the spring actuated parking brakes. The vehicle may then be towed in an emergency.

Outside air source can be used only if protected system is in operating condition.

On W and WT-Series trucks, the Schrader valve is located on the air manifold under the right front side of the cab (just above right headlamp).

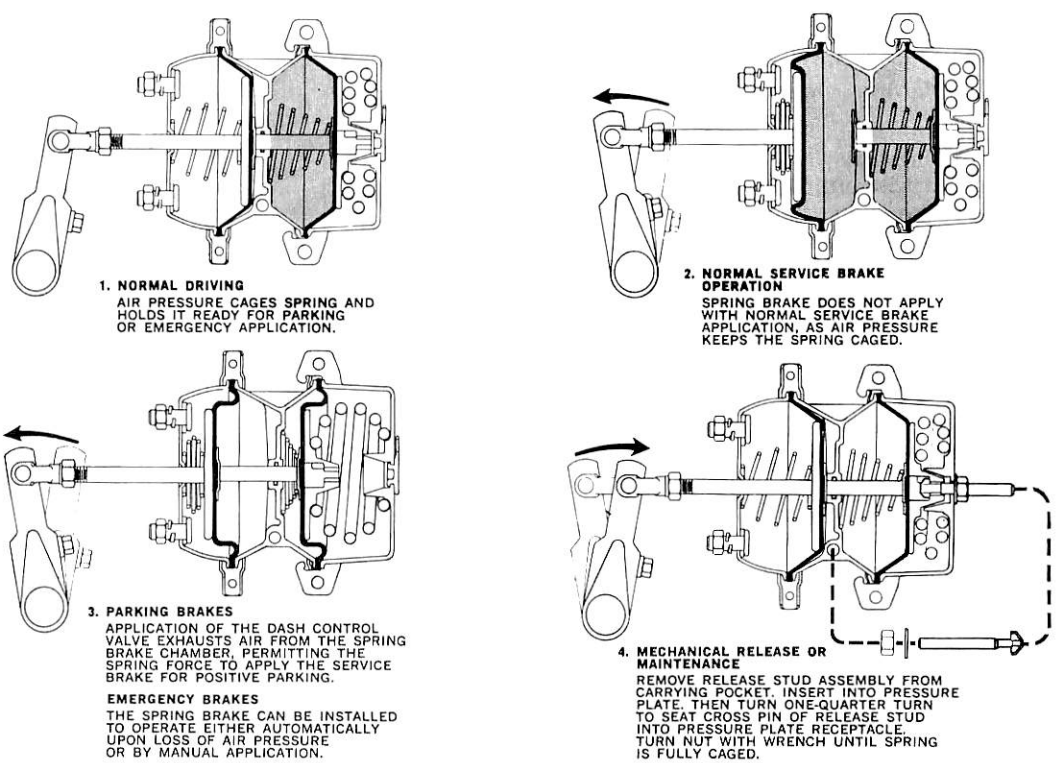

FIG. 1 Anchorlok Brake Operation and Mechanical Release

ADJUSTMENTS

MANUAL (MECHANICAL) RELEASE OF PARKING BRAKE

If necessary to move the vehicle after an emergency application (before air pressure can be restored), the emergency-parking spring can be compressed mechanically to release the brake as follows: A release stud (spring caging tool) is attached to each brake chamber assembly.

Remove the release stud tool and nut from the carrying pocket on the chamber assembly. Remove the access plug from the end of the spring chamber. Insert the release stud through the opening in the chamber and into the spring pressure plate (Fig. 1). Turn the release stud one-fourth (1/4) turn to engage the tangs on the release stud into the slot in the pressure plate. Install the nut on the release stud. Be sure the tang on the release stud stays engaged with the slot on the pressure plate while installing the nut. Tighten the nut with the wrench to compress the spring. Continue turning the nut until the spring is fully caged.

Do not loosen or remove the release stud and nut unless the brake chamber is completely assembled and is securely clamped.

REMOVAL AND INSTALLATION

AIR CHAMBER ASSEMBLY

Removal

1. Release all the air from the system, and then disconnect the air lines from the brake chamber.
2. Mechanically cage (compress) the parking brake spring (Fig. 1).
3. Disconnect the push rod yoke from the slack adjuster.
4. Remove the mounting nuts and remove the brake chamber.

Installation

1. Position the brake chamber assembly on the mounting bracket and install the attaching nuts.
2. Connect the push rod yoke to the slack adjuster.
3. Connect the air lines to the brake chamber and build up the air pressure.
4. Reset the parking brake.

DISASSEMBLY AND ASSEMBLY

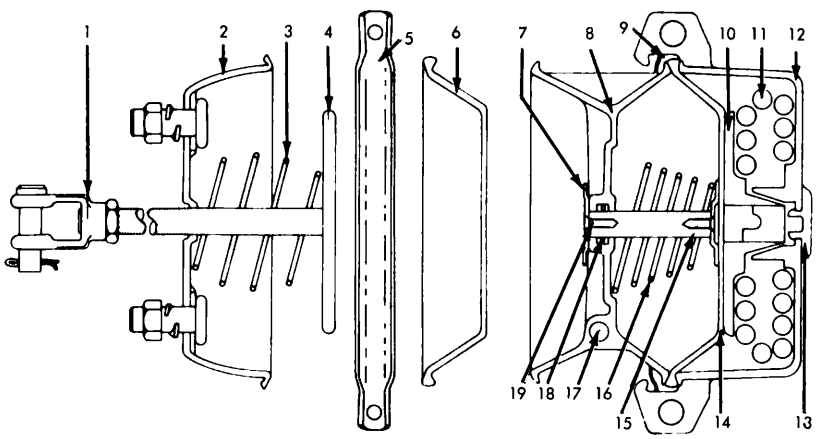
AIR CHAMBER DIAPHRAGM REPLACEMENT

The service and/or parking brake diaphragm can be replaced without removing the brake unit from the vehicle as follows:

Disassembly

Refer to Fig. 2.

1. Compress (cage) the parking brake spring as described under Mechanical Release of Parking Brake.
2. Remove the parking brake housing-to-adapter clamp.
3. Remove the parking brake housing, spring and pressure plate as an assembly **(the spring, spring housing and pressure plate are serviced as an assembled unit).**
4. Remove the parking brake diaphragm.
5. Remove the adapter-to-service chamber clamp.
6. Remove the adapter and the service brake diaphragm.



1. CLEVIS ASSEMBLY
2. SERVICE BRAKE HOUSING

H1833-A

FIG. 2 Anchorlok Brake Parts Identification

Assembly

1. Position a new service brake diaphragm squarely on the service brake body. Position the adapter assembly on the service brake body and install the adapter-to-service brake chamber clamp. Tighten the clamp bolts evenly.
2. Position a new parking brake diaphragm squarely on the adapter housing. Position the parking brake housing, spring and pressure plate assembly on the adapter housing and install the retaining clamp. Tighten the clamp bolts evenly.
3. Charge the air chambers with air and check for leaks.
4. Remove the parking brake release stud and nut. Replace the release stud and nut in the storage location provided on the brake chamber. Install the access plug in the parking brake chamber.

TESTING

When diagnosing steering problems, refer to the Truck Diagnosis Manual for the detailed information on the items that could be causing the problem. The following preliminary checks should be made before proceeding with other diagnosis checks.

POWER STEERING—PRELIMINARY CHECKS

These important preliminary checks should always be made before performing any power steering operations. When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

PUMP BELT CHECK

If the pump belt is broken or worn, replace it with a new belt. **Use only the specified type of belt. Check the belt tension. An excessively tightened belt causes serious pump wear, and an excessively loose belt results in squeal. Refer to the appropriate power steering section for belt adjustment.**

AIR BLEEDING

Air in the power steering system (shown by bubbles in the fluid) should be bled. Bleeding the air from the power steering fluid is done by exercising the power steering components. After making sure that the reservoir is filled to specification (the fluid must be at normal operating temperature when the

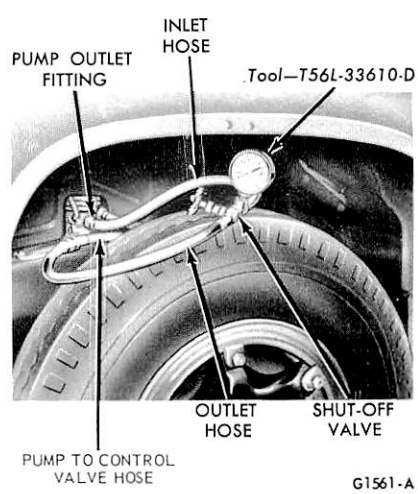

FIG. 1 Pressure Test—Non Integral Steering Gears

check is made), turn the steering wheel through its full travel three or four times. **Do not hold the wheels against their stops.** Recheck the fluid level.

FLUID LEVEL CHECK

Run the engine until the fluid is at normal operating temperature. Then turn the steering wheel all the way to the left and right several times. Make sure that the wheels are in the straight ahead position, then shut off the engine.

Check the fluid level in the power steering reservoir on Ford-Thompson pumps. The level must show on the cross hatching between the bottom of the dipstick and the full mark. If the level is low, add power steering fluid D2AZ-19582-A. **Do not overfill the reservoir.** Remove excess fluid with suction device.

FLUID LEAK CHECK

1. If the power steering fluid does not already include dye, premix one teaspoonful of oil-soluble aniline dye with 2 pints of power steering fluid. Then refill the reservoir with the dye solution.
2. With the engine running at idle speed, turn the steering wheel all the way to the right and to the left several times to distribute the dye solution throughout the hydraulic system. Do not hold the wheels against their stops for more than 5 seconds.
3. Shut off the engine, and check for leaks.

FITTING AND TUBES SEAT LEAK INSPECTION

Since most fluid leaks occur at the fittings and connections in a power steering hydraulic system, these parts should be checked before any other part is replaced.

1. Clean the outside of the integral steering gear and/or the control valve and the power cylinder, the bottom surfaces of the pump, and all lines and fittings. Dirt, oil, and grease should be removed from all areas where leaks may exist.
2. Tighten all fittings, using a special 5-flat tube wrench. **Do not tighten the fittings with a standard open end wrench.** If a properly tightened fitting leaks, replace the seat.

FIG. 2 Power Steering Pump Pressure Relief Valve Settings

PUMP, CONTROL VALVE, AND POWER CYLINDER LEAK INSPECTION

If the fittings and connections do not leak, check the other parts of the system.

PUMP RESERVOIR LEAKS

Leak points at the pump reservoir may be caused by improper installation or by a worn or damaged cover or reservoir gasket. A worn or damaged stud gasket on the stud at the center of the cover or at the rear of the reservoir may also cause leakage.

Pump Leaks (Eaton)

Leakage may occur at the O-rings in the orifices at the top of the pump body. The reservoir must be removed from the pump to replace these O-rings.

Other pump leak points are the shaft seal at the front of the pump, the pump housing O-ring and the flow director O-ring between the two halves of the pump, and the relief valve plug O-ring. Replace only parts as required.

Pump Leaks (Ford-Thompson)

Leak points at the reservoir may be caused by improper installation of the reservoir or by a damaged reservoir O-ring seal. A damaged fitting gasket at the rear of the reservoir may also cause leakage.

Other external pump leak points are the pump shaft seal and pressure fitting.

CONTROL VALVE LEAKS

If the control valve is leaking (somewhere other than the tube seats), replace all the seals, using a control valve seal kit. Use all the parts in the kit, and be sure they are correctly installed.

Some fluid remaining from the manufacturing processes may be found in the sleeve near the ball stud. Do not confuse this fluid with leaking fluid from the hydraulic system.

POWER CYLINDER LEAKS

The power cylinder may leak at the piston rod seal. A power cylinder seal kit should be used to correct leakage. **Do not replace the power cylinder assembly unless the piston rod is scored or has a dull gray finish instead of a high luster chrome finish.**

PUMP-FLUID PRESSURE TEST (EATON PUMP)

A fluid pressure test will show if the pump or some other unit in the power steering system is causing the trouble. The steps below should be used to find the trouble.

1. Measure the pump belt tension. **When adjusting the belt tension on a power steering pump, do not pry against the pump to obtain the proper belt load.**

   A half-inch case boss has been incorporated on the front face of the pump cover plate onto which a 9/16 inch open end wrench can be fitted to pry the pump and obtain the proper belt tension on 6 cylinder engines. On all 8 cylinder engines, leverage should be applied to the pump mounting bracket and the pump pulley hub to obtain the proper belt tension.
2. Disconnect the pressure line hose from the pump outlet, and install a 0-2000 psi pressure gauge (Tool T56L-33610-D) and shut off valve between the end of the hose and the pump outlet (Fig. 1).

   Be sure that the pressure gauge is between the pump and the shut off valve, all connections are tight, and the shut off valve is fully open.
3. Connect a tachometer to the engine.
4. Start the engine and operate it at idle speed for at least two (2) minutes to warm up the fluid.
5. Cycle the steering wheel from stop-to-stop several times to expel any air from the system; stop the engine. Remove the reservoir filler cap and check the fluid level in the reservoir. If necessary, add lubricant (C1AZ-19582-A) to the proper level.
6. With the engine running at approximately 1000 rpm and no steering effort applied, and the lubricant at normal operating temperature, the pressure gauge should show a pressure no greater than 80 psi. If the pressure is higher inspect the hoses for kinks and obstructions.
7. Decrease the engine speed to 600 rpm, then slowly close the gauge shut-off valve. With the valve fully closed, the pump pressure should be to maximum pressure (Fig. 2). **Do not close the valve for more than a few seconds (maximum 5 seconds), as this would abnormally increase the lubricant temperature and cause undue pump and/or steering gear wear. Engine rpm should not exceed fast idle during this test.**
8. If the pressure increases to more than the high limit of the relief pressure range, the pressure relief valve is not operating properly, and a pump overhaul or replacement is indicated.
9. If the pressure, with the shut-off valve fully closed, is less than the minimum relief pressure, the trouble is in the pump. If the pressure increases to the specified relief pressure range, the trouble is somewhere else in the power steering system.
10. After the fluid pressure test is completed, shut off the engine and remove the pressure testing tool and the tachometer. Make the necessary repairs to eliminate the trouble in the system.

FORD-THOMPSON POWER STEERING PUMP FLOW AND PRESSURE TESTS

It is important that the pump flow and pressure tests detailed here be performed before overhaul procedures are undertaken. The malfunction of the steering system should be caused by another component other than the pump. Steps outlined below should be followed to determine if the pump is the cause of the trouble.

PUMP FLOW TEST

1. Depending on the equipment present on the vehicle (air conditioning, power brakes, standard transmission), one of the following options may be used to connect the pump pressure and return hoses (Fig. 3) to the test tool (T56L-33610-D and T68L-33610-A):
   a. Disconnect the pressure and return lines at the power steering pump. Obtain a power steering return hose from stock and connect the end with the fitting to the output fitting of the tool using the 5/8-18 SAE female, 1/4 N.P. thread male fitting provided. The end of the stock hose (without the fitting) should be connected to the return tube of the pump. Connect the pressure hose from the tool to the outlet fitting of the pump.
   b. Disconnect the pressure line at the pump and connect the pressure line from the test tool to the outlet fitting of the pump. Disconnect the return line at the gear and connect it to the output fitting of the tool, using the 5/8-18 SAE female, 1/4 N.P. thread male fitting provided.
2. After installing the lines by the most advantageous method, proceed as follows:
3. Open the manual valves A and B fully.
4. Connect a tachometer, start the engine and operate it at idle speed **until the reservoir fluid temperature reaches 165 degrees to 175 degrees. This temperature must be maintained throughout the test. Valve B may be partially closed to create a back pressure up to 350 psi to hasten the temperature rise. The**

reservoir fluid must be at the proper level.

5. With the engine operating at recommended idle rpm and fluid temperature noted in Step 4, close the manual valve B. The minimum acceptable pressure reading is 620 psi.
6. If the pressure gauge reading is **below** the minimum specification, the pump is at fault and should be repaired with necessary parts.
7. If the reading is **at or above** the minimum specification, the pump flow is normal. Open manual valve B and proceed to the Pump Fluid Pressure Test.

PUMP FLUID PRESSURE TEST

1. Keep the lines and tools connected as in the Pump Flow Test.
2. With manual valves A and B open fully, operate the engine at recommended idle speed. Close manual valve A, then manual valve B. **Do not keep both valves closed for more than 5 seconds as this would abnormally increase the fluid temperature and cause undue pump and/or gear wear.**
3. With the valves fully closed, the pressure gauge should read 1200 psi minimum for F-100, F-250 and F-350 (4 x 2) trucks.
4. If the pressure gauge reading is **below** the minimum specification, the pump is at fault and should be repaired with necessary parts.
5. If the pressure gauge reading is **at or above the minimum specifications, the pump is normal and the power steering gear is at fault.**

ADJUSTMENTS

STEERING GEAR LUBRICANT CHECKING PROCEDURE

F-100, F-250 AND 350 (4 X 2) SERIES MANUAL STEERING

1. Center the steering wheel.
2. Remove the steering gear housing filler plug.
3. Remove the lower cover-to-housing attaching bolt.
4. With a clean punch or like instrument, clean out or push the loose lubricant in the filler plug hole and cover-to-housing attaching bolt hole inward.
5. Slowly turn the steering wheel to left until linkage reaches stop. Lubricant should rise within the cover lower bolt hole; then slowly turn the steering wheel to the right until linkage reaches stop. Lubricant should rise within the filler plug hole. If lubricant does not rise in both the cover bolt hole and the filler plug hole, add lubricant until it comes out both holes during this check.
6. Install the lower cover-to-housing attaching bolt and the filler plug.

ECONOLINE

1. Remove the steering gear housing filler plug.
2. With a clean punch or like instrument, clean out or push the loose lubricant into the filler plug hole. Turn the steering wheel to the left until linkage reaches stop. Then turn the steering wheel slowly to the right until linkage reaches stop. Lubricant should rise in the filler plug hole. If lubricant does not rise in the filler plug hole, add lubricant.

The location of the steering gear does not allow clearance for the removal of a cover bolt for creating a vent. To prevent air from being trapped and forming pockets in the housing while lubricant is being added, it is suggested that a curved length of 1/4 inch tubing be adapted to the end of the grease gun being used. This tube should be inserted into the filler hole and extend down toward the bottom of the housing cavity. By this method, the lower housing cavity will fill first and as lubricant is added, air will be expelled upward and out the filler hole.

To add lubricant, turn the steering wheel to the extreme left to position the ball nut away from the filler plug hole and fill gear by method described above until lubricant rises in the filler plug hole.

F-100 Four-Wheel Drive, Bronco

1. Remove the filler plug from the sector shaft cover.
2. Check to see if the lubricant level is visible in the filler plug-tower. If the lubricant is visible, install the filler plug. If the lubricant is not visible, add fluid as outlined in Step 3.
3. Add steering gear lubricant until the lubricant level is visible approximately 1 inch from the top of the hole in the filler plug tower; then, install the filler plug.

ALL MODELS—500 THRU 9000, F-250 FOUR-WHEEL DRIVE AND P-SERIES WITH MANUAL STEERING

1. Remove the filler plug from the top of the steering gear housing.
2. Check the lubricant level. If the level is to the bottom of the filler plug

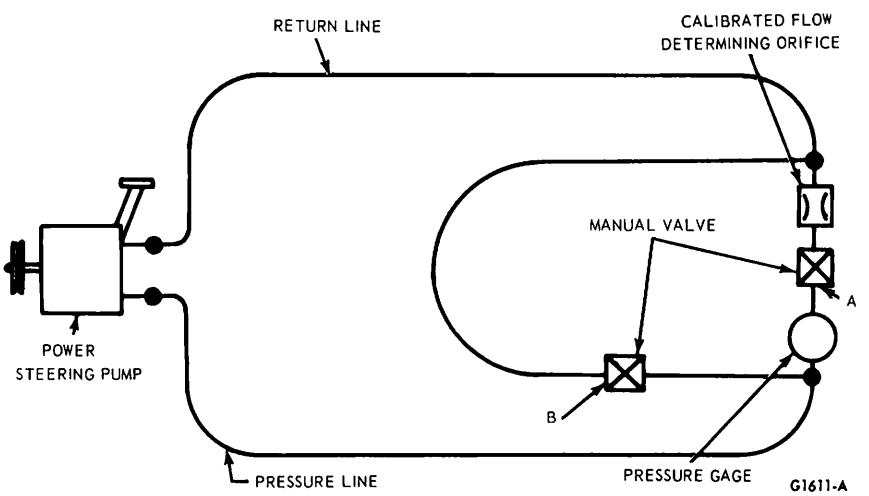

FIG. 3 Power Steering Pump Test Circuit Diagram

opening, install the filler plug. If the level is not to the bottom of the filler plug hole, add fluid to raise the level to that level. **Do not use a pressure gun as it could damage the seals in the gear.** The Model 504 manual gear when used on L and W-Series trucks are equipped with drain plugs to facilitate servicing.

ROSS SEMI-INTEGRAL POWER STEERING GEAR

1. Remove the uppermost filler plug from the gear housing.
2. Fabricate a 90 degree x 3/8 male x 3/8 female pipe elbow and install in the filler plug hole of the gear as shown in Fig. 4.
3. Add specified lubricant into the open end of the elbow until visible.
4. Install the plug removed in Step 1 in the 3/8 female hole of the fabricated elbow.

CLEANING AND INSPECTION

MANUAL STEERING GEAR

Do not clean, wash or soak seals in cleaning solvent.

Wash all steering gear parts in a cleaning solvent. Then wipe them dry with a lint-free cloth.

Check for scores, chips, or cracks in the worm. Check the steering shaft for straightness. Check the condition of the splines and threads at the end of the shaft. Inspect the worm bearing seats for wear or irregular surfaces. Replace the shaft and worm if wear or damage is present.

Inspect the sector shaft. Check the roller for scores, chips, or cracks. Check the condition of the sector shaft at the bushing locations. Replace the sector shaft assembly if any of these parts are worn or damaged.

Inspect the worm roller or ball bearings, and the sector shaft bushings or roller bearings for wear or damage. Inspect the worm bearing cup for pits, scores, or other damage. Replace the parts that are worn or damaged.

Inspect the steering gear housing, the sector shaft cover, and the housing end plate for cracks or other damage, and replace the parts if necessary.

ROSS SEMI-INTEGRAL POWER STEERING GEAR

Clean all parts in cleaning solvent. Then, wipe them dry with a clean lint free cloth. **Do not steam clean the steering gear.** Be careful not to nick the parts or allow them to bump together during the cleaning process.

Check the cam groove for chipping, scoring or other damage. The operation of the stud in the cam groove will wear away the copper plating on the cam. This is a normal condition and the cam does not require replacing. Check the condition of the bearing surfaces at each end of the cam.

Check the sector shaft for burrs on the splines, twisted splines and wear on the bearing surfaces. Check the stud for nicks, flat spots or chipped roller bearings. Check the adjustment of the stud roller bearing.

Check the gear housing for strain at the mounting flanges. Check the condition of the needle bearings in each end of the housing and the fit of the cam in the needle bearings. Check the sector shaft bushings for wear or out-of-round condition.

Check the actuator, actuator housing, bearings, and thrust washers for wear or other damage.

POWER STEERING PUMP

EATON

Wash all pump and reservoir parts in a cleaning solvent, and wipe them dry with a lint-free cloth.

Inspect the pump housing and cover for wear caused by turning of the rollers and the carrier. Check the carrier shaft bearings in the housing and the cover for wear or scores. Replace the bearings if necessary.

Inspect the carrier, shaft, and rollers for wear or any kind of damage. If there is wear or damage, replace the appropriate part(s). **A damaged roller, carrier, or insert should not be serviced alone; these parts are serviced in a kit, and all parts of the kit should be used.** If the retaining ring on the carrier shaft is bent or broken, replace it.

Be sure the valve assembly and its bore are dry. Insert the valve in the housing, and check for free movement of the valve in the bore. Using crocus cloth, remove any burrs from the valve.

Inspect the carrier shaft seal in the pump housing for wear or damage. If there is wear or damage, carefully remove the seal with a punch, avoiding damage to the shaft bushing. **Remove the seal only for replacement.**

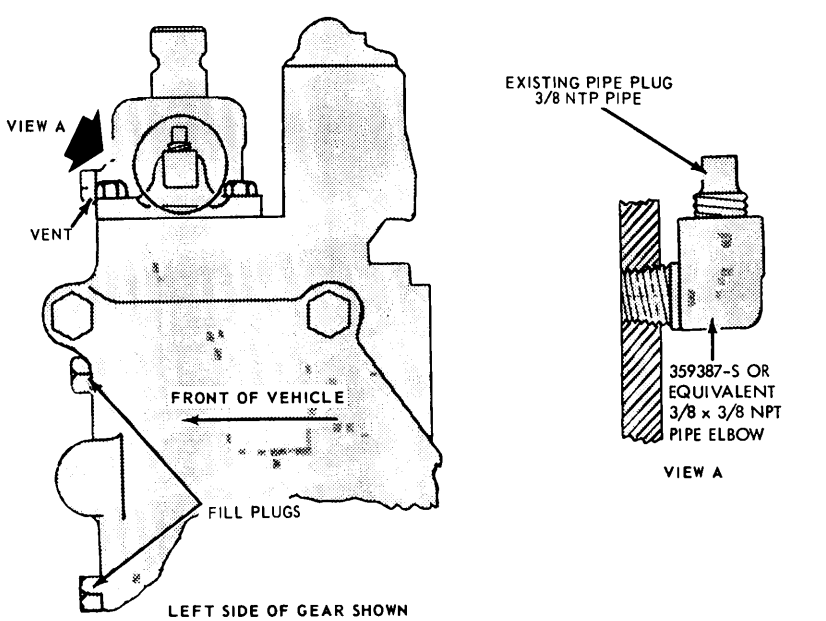

FIG. 4 Ross HPS-70 Steering Gear Lubricant Fill—W-Series

FORD-THOMPSON

Wash all parts (except seals) in a Naphtha or Chlorinated type solvent and dry with compressed air.

The following procedure should be followed when cleaning the relief valve which is a part of the pump valve assembly.

1. Using a punch or rod of suitable diameter, apply an even pressure in a straight line to the tip of the relief valve pin (Fig. 5). Depress the valve two or three times to exhaust the oil which is trapped in the assembly. Do not hammer on the valve pin or housing.
2. Submerge the assembly in a container of **clean** solvent. Again applying an even pressure to the tip of the relief valve pin, (a sudden strong force could push the pin through the relief valve spool) move the valve in and out several times, thereby thoroughly flushing the assembly. Pressure created within the valve bore when the valve is moved inward should force the cleaning fluid out through the sensing orifice. If this does not occur, the sensing orifice should be cleaned with a piece of wire. The valve must move freely and evenly. If the pin is bent or damaged, or if the valve binds, the pump valve must be replaced.

The following describes the components of the power steering pump which must be replaced **regardless of condition and replacd regardless of condition** and how to determine when other components should be replaced.

The outlet fitting hex nut may be reused if the corners of the hex are not rounded. The housing bolts may be reused if the threads are not damaged.

All gaskets and seals must be replaced with new components except the rotor shaft seal which should be reused unless it was leaking.

The reservoir assembly may be reused if the reservoir seal and gasket areas are not damaged (scratches, dents, etc). The soldered joints of the return and fill tubes must not be loose or bent. Be sure to check for a broken baffle.

The housing or housing assembly may be reused if there is no damage (scratches, etc) at reservoir gasket, outlet fitting or cover seal areas.

If the outlet fitting is damaged, the pump housing must be replaced. The pressure plate springs may be reused providing they are not bent, broken or have not taken a set.

Do not reuse the retainer end plate if it is burred or damaged. The upper pressure plate may be reused if there is no scoring on the wear surface. It is acceptable to polish the phosphate coating.

The rotor and cam assembly can be reused if there is no wear other than the removal of the phosphate coating on the cam contour. Do not disassemble the rotor and cam assembly. Push the rotor part way out the cam insert taking care not to let the slippers and springs fall out. Check the cam ID for scoring and burning. Check the rotor faces and OD for scoring and chipping. Do not attempt to repair or refinish the lower and upper pressure plates, cam or rotor assembly. When wear or burning is encountered, replace them with new components.

Install a new rotor and cam assembly if the slippers are worn. Replace the springs if they are bent or broken. Polishing the phosphate coating of the slipper sealing surface is permissible.

The rotor shaft can be reused if the front and rear thrust faces, the bushing diameter and the shaft seal diameter are not excessively worn or scored.

The housing plate and bushing assembly may be reused if all of the threaded holes are not damaged beyone repair and the bushing diameter is not scored or worn .0005 inch over the maximum dimension of .6897 inch. Threaded holes can be repaired by drilling out the damaged threads and installing a heli-coil insert. If the bushing is scored or excessively worn, a new plate and bushing assembly must be installed.

With Tool T69P-3D608-A (using a dial indicator) check the squareness of the fixed dowel pin in the plate (Fig. 6). The pin must be square with the adjacent surface within .001 inch per inch through a 180 degree arch.

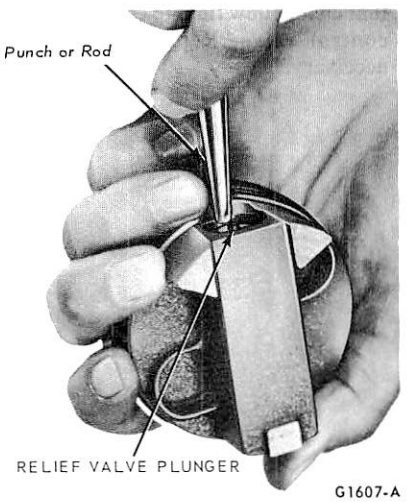

FIG. 5 Cleaning Pump Relief Valve

FIG. 6 Dowel Pin Squareness Check

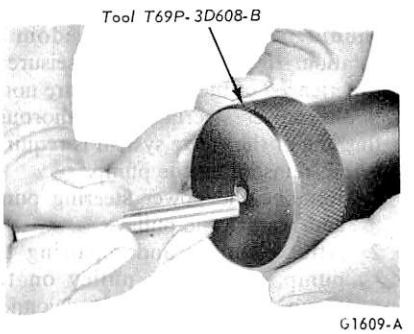

FIG. 7 Dowel Pin Insertion

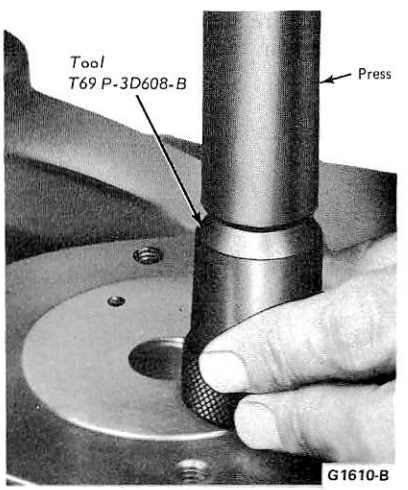

FIG. 8 Replacing Dowel Pin

A bent or broken dowel pin can be replaced as follows:

1. Hold the plate assembly in a horizontal position and grip at least an inch of the dowel pin in a vise. Tap the plate with a plastic or a rubber hammer to pull the pin from the plate.
2. Insert the support guide (Tool T69P-3D608-B) over a dowel pin (Fig. 7) and press the pin into the plate to a height of 1.68 inch. (See Fig. 8). The support guide tool will serve as a stop guide. Be careful not to bend the new dowel pin during installation.
3. Again use Tool T69P-3D608-A (with a dial indicator) to check the dowel pin squareness as outlined above.

FLUSHING THE POWER STEERING SYSTEM (WITH FORD—THOMPSON PUMP)

Should a power steering pump become inoperative, the shaft and pulley should be checked for freedom of rotation. If a pump bind or seisure is experienced or metal particles are noted in the power steering fluid, thorough flushing of the entire system is required before reinstalling the pump.

1. Remove the power steering pump and remove the pulley.
2. After cleaning and repairing the pump, install the pulley on the pump. Install the pump and connect only the pressure hose to the pump.
3. Place the fluid return line in a suitable container and plug the reservoir return pipe at the pump.
4. Fill the reservoir with fluid (C1AZ-19582-A).
5. Disconnect the coil wire to prevent the engine from starting and raise the front wheels off the ground.
6. While approximately two quarts of fluid are being poured into the reservoir, turn the engine over using the ignition key, at the same time cycle the steering wheel from stop to stop.
7. As soon as all of the fluid has been poured in, turn off the ignition key, and attach the coil wire.
8. Remove the plug from the reservoir return pipe, and attach the return hose to the reservoir.
9. Check the reservoir fluid level; if low, add fluid to the proper level. **Do not overfill.**
10. Lower the vehicle.
11. Start the engine and cycle the steering from stop to stop to expel any trapped air from the system.

POWER STEERING POWER CYLINDER

After cleaning the outside of the power cylinder and piston rod, wipe the parts dry.

Inspect the cylinder and piston rod for wear or damage. The internal parts of the cylinder, except the seal assembly and hose seats, and the rod cannot be repaired or replaced. If either the cylinder or rod is worn or damaged, or if the piston is leaking internally, the entire lower cylinder assembly must be replaced as a unit. The cylinder seals and hose seats are replaceable.

Inspect the mountings bushings and insulators for wear or damage, and replace them if necessary.

POWER STEERING CONTROL VALVE

Thoroughly clean all parts of the control valve assembly, and inspect them for wear or damage. **Do not use cloth waste to wipe the parts.**

Inspect the control valve seals for wear or damage. Examine the lips of the seals carefully for nicks or scratches that could allow fluid to escape from the control valve. Replace the seals if necessary.

Inspect the control valve spool carefully for burrs and scoring. Remove the burrs with crocus cloth. Do not round off the sharp edges on the spool as the operation of the valve may be affected.

Inspect the control valve housing for burrs and scored or damaged surfaces.

Remove the burrs with crocus cloth. Dry the valve spool and housing thoroughly, and insert the spool in the housing. The spool should fall freely of its own weight through the housing.

Inspect the mating surfaces of the inner and outer sleves for wear or damage. The surfaces should be free of burrs and scores. Minor burrs and scores may be removed with crocus cloth. Prior to assembly, the outer diameter of the inner sleeve should be coated with C1AZ-19590-B grease. Check the fit of the inner sleeve in the outer sleeve (Fig. 9). The inner sleeve should slide freely in the outer sleeve.

Check the ball stud seats and spring for wear or damage, and replace them if necessary.

PART 13-05 Steering Column-Shift Rod Above Tube

Applies To Econoline, P-Series Only			
COMPONENT INDEX	**Page**	**COMPONENT INDEX**	**Page**
STEERING COLUMN		Description	05-01
Alignment	05-02	Removal and Installation	05-03

DESCRIPTION

STEERING COLUMN

The Econoline and P-Series vehicles are equipped with columns which have a shift control rod mounted separately above the column tube (Figs. 1 and 2).

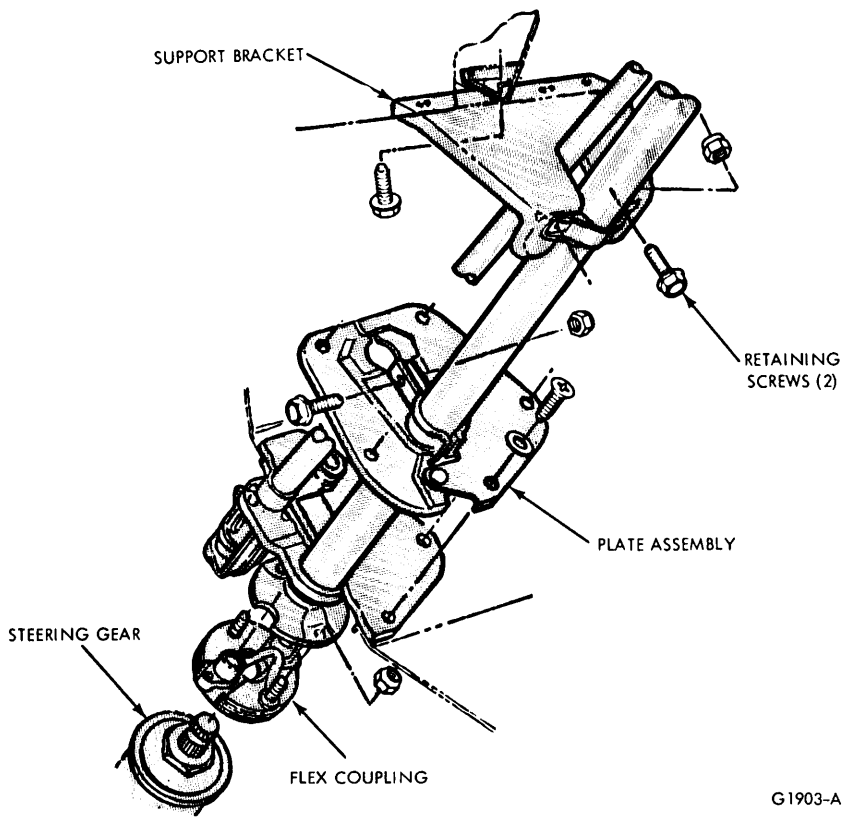

FIG. 1 Steering Column Installation—Econoline

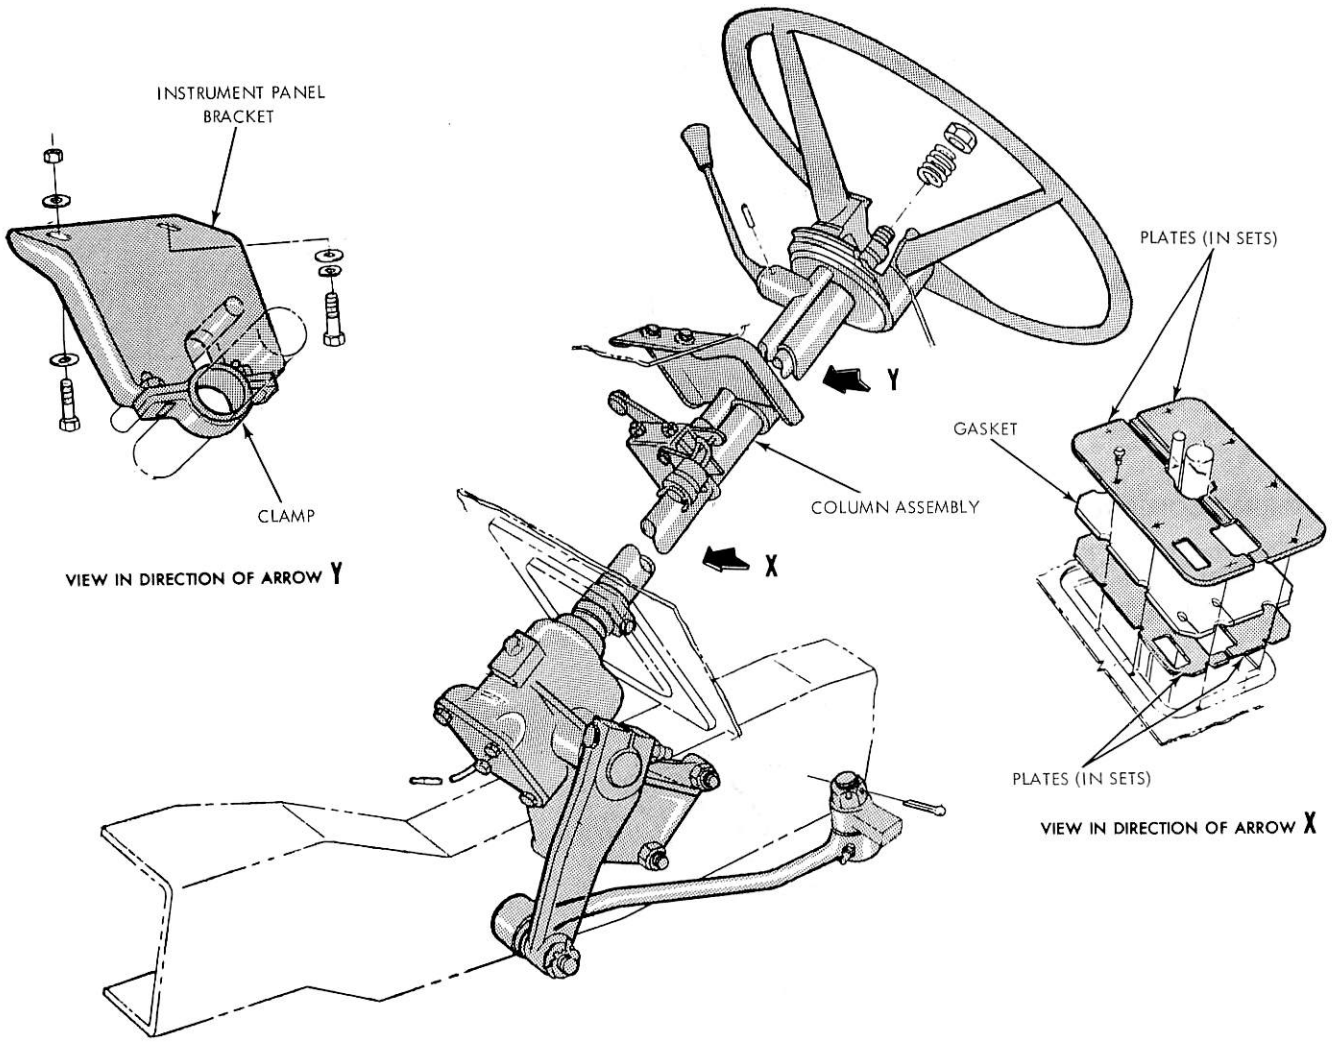

FIG. 2 Steering Column Installation—P-Series

ADJUSTMENTS

STEERING COLUMN

Steering column misalignment can cause hard steering or failure of the flexible coupling. It is therefore important to check steering column alignment before attempting to diagnose steering problems or whenever a steering gear or column has been replaced.

1. Raise the front end of the vehicle and position safety stands under the front axle.
2. Remove the horn button or ring and connect an in-lb torque wrench as shown in Fig. 3.
3. If the torque required to turn the steering wheel exceeds the specification a binding condition exists and the steering column and/or gear must be adjusted.

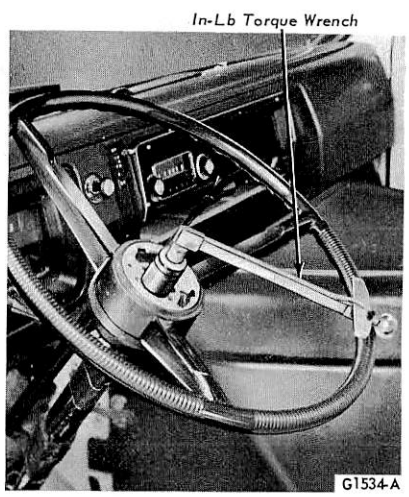

FIG. 3 Checking Steering Shaft and Gear Turning Effort

REMOVAL AND INSTALLATION

ECONOLINE

Removal

1. Disconnect the horn, turn signal and back-up light wires.
2. Remove the steering wheel.
3. Disconnect the shift rods at the column shift levers.
4. Disconnect the flex coupling to the steering gear.
5. Remove the clamp retaining the column to the support bracket on the instrument panel (Fig. 1).
6. Remove the five screws retaining the plate assembly to the floor pan.
7. Remove the bolt and nut from the plate assembly clamp.
8. Lift the column from the vehicle.

Installation

1. Position the column in the vehicle.
2. Install the column bracket retaining screws to the support bracket on the instrument panel.
3. Align the flex coupling to the steering gear and install the retaining nuts.
4. Install the five screws retaining the plate assembly to the floor pan.
5. Install the bolt and nut into the plate assembly clamp.
6. Connect the shift rods to the column shift levers.
7. Install the steering wheel.
8. Connect the back-up light, turn signal and horn wires.

P-SERIES

Removal

1. Disconnect the horn, turn signal and back-up light wires.
2. Remove the steering wheel.
3. Disconnect the shift rods at the column shift levers.
4. Disconnect the steering column to the steering gear.
5. Remove the two clamp bolts and nuts retaining the column to the instrument panel bracket.
6. Remove the eight screws attaching the four plates and gasket to the floor pan (Fig. 2).
7. Lift the steering column out of the vehicle.

Installation

1. Position the column in the vehicle.
2. Attach the column to the steering gear.
3. Install the eight screws attaching the plates and gasket to the floor pan.
4. Install the two bolts and nuts to attach the steering column to the instrument panel bracket.
5. Connect the shift rods to the column shift levers.
6. Install the steering wheel.
7. Connect the horn, turn signal and back-up light wires.

SHAFT BUSHING

Removal and Installation

1. Remove the steering column as described earlier.
2. Remove the outer snap ring from the steering shaft and pull the shaft out of the tube. The inner snap ring will pull the bushing assembly from the steering tube as the shaft is withdrawn.
3. Remove the inner snap ring. Remove and discard the lower bushing assembly.
4. Apply a coat of Lubriplate type lubricant to the inside (cone shaped) area of the new bushing and slip it over the steering shaft with the conical area facing the top of the steering shaft.
5. Install the inner snap ring on the shaft, insert the shaft and bushing into the steering column and retain them with the outer snap ring.
6. Install the steering column as described earlier.

PART 13-06 Steering Column-Shift Rod Within Tube

Applies To F-100–350, Bronco Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
SHIFT TUBE		STEERING COLUMN - Cont.	
Removal and Installation	06-03	Description	06-01
STEERING COLUMN		Removal and Installation	06-02
Alignment	06-02		

DESCRIPTION

STEERING COLUMN

The F-100-350 and Bronco vehicles are equipped with columns which are designed with the shift tube within the column tube (Figs. 1 and 2).

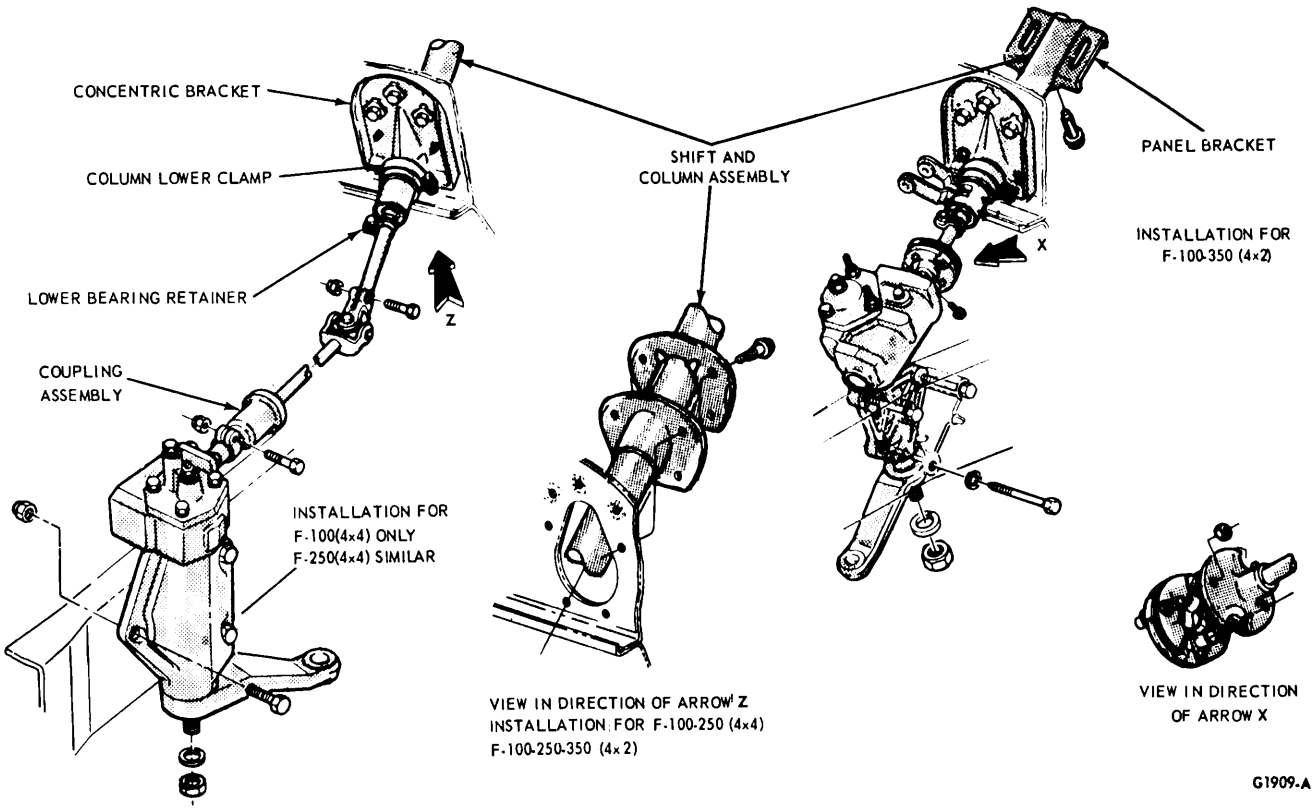

FIG. 1 Steering Column Installation F-100-350 (4 x 2), F-100-250 (4 x 4)

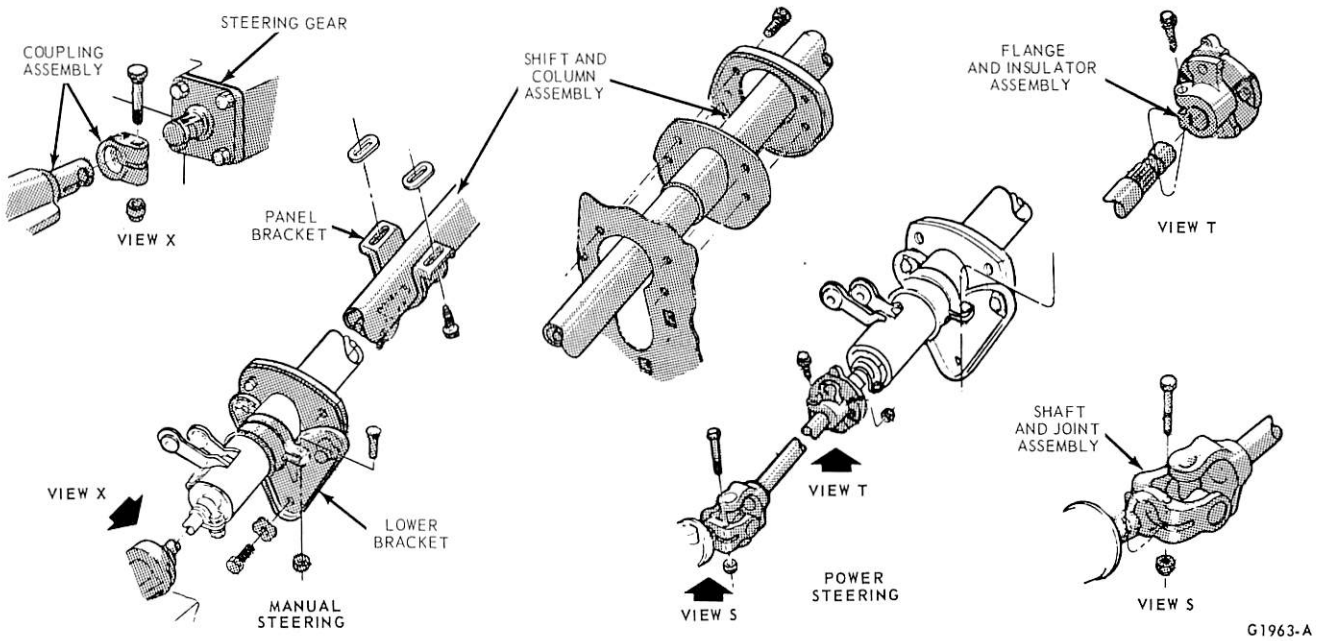

FIG. 2 Steering Column Installation Bronco

ADJUSTMENTS

STEERING COLUMN ALIGNMENT—F-100 THRU 350

Before checking the steering gear adjustments, eliminate any steering column tube and steering shaft stresses or misalignment as follows:

1. Loosen the screws attaching the steering column to the instrument panel, the column lower clamp, the concentric bracket bolts and the lower bearing retainer (Fig. 1).
2. Position the concentric bracket and torque the attaching bolts to 12-18 ft-lbs.
3. The front wheels must be in a straight ahead position. With the fabric insulator of the flexible coupling held in a flat plane, pull the steering column (inside the cab) upward until the gap between the lower edge of the steering wheel hub and steering column is .03 to .06 inch.
4. Tighten the steering column bracket-to-instrument panel screws and torque to 10-15 ft-lbs. On units with power steering, torque the two set screws to 4-6 ft-lbs.
5. Slide the lower bearing retainer up against the lower bearing and torque the nut and bolt to 10-15 ft-lbs.
6. Check the flexible coupling for the minimum clearance between the slots and coupling pins (.073 inch minimum either side). Tighten the steering column clamp bolt and nut and torque to 18-25 ft-lbs.
7. Road test the vehicle to check for correction of problem.
8. Recheck the flexible coupling to verify the slot and coupling pin clearance specification.

REMOVAL AND INSTALLATION

STEERING COLUMN

F-100-250 (4 X 4), F-100-250-350 (4 X 2)

Removal

1. Disconnect the ignition switch wire connector, back-up light wires and neutral start switch (if so equipped).
2. Remove the horn switch steering wheel.
3. Disconnect the shift rods at the column shift levers (if so equipped) (Fig. 1).
4. Disconnect the flex coupling or coupling assembly (Fig. 1) at the steering gear.
5. Remove the two screws retaining the column to the instrument panel.
6. Remove the three bolts (from the engine compartment) and four screws (cab side) that retain the column bracket to the floor pan.
7. Loosen the clamp that retains the column bracket to the column.
8. Lift the column out of the vehicle.

Installation

1. Position the column in the vehicle.
2. Install the two screws retaining the column to the instrument panel.
3. Align the flex coupling or coupling assembly to the steering gear and install the retaining nut(s).
4. Install the three bolts (from the engine compartment) and four screws (cab side) to retain the column bracket to the floor pan.
5. Secure the column to the column bracket with the column bracket clamp.
6. Connect the shift rods to the shift levers (if so equipped).

7. Install the steering wheel on the steering shaft. The gap between the lower edge of the steering wheel hub and the steering column should be .03 to .06 inch. The column should be loosened, if necessary, to obtain this specification.
8. Connect the horn switch, back-up light wires and ignition switch wire connector (if so equipped).

BRONCO

Removal

1. Disconnect ignition switch wire connector and back-up light wires.
2. Remove two screws retaining the safety pad and horn ring. Remove both components.
3. Remove the steering wheel.
4. On units with manual steering, remove the coupling assembly retaining bolt and nut. On units with power steering, remove the flange and insulator pinch bolt (Fig. 2).
5. Disconnect the shift rods at the column shift levers.
6. Remove the clamp retaining the column to the support bracket on the dash panel.
7. Remove the five nuts retaining the column support bracket, rubber dust seal and plate assembly to the dash panel.
8. Remove the four screws retaining the trim cover. Remove the trim cover.
9. Remove the four column-to-upper support bracket retaining bolts.
10. Remove the four bolts retaining the column upper support bracket to obtain clearance.
11. Remove the plate and dust seal assembly from the dash panel and remove the column assembly.

Installation

1. On manual steering units, position the column through the opening in the instrument and dash panels and align the flex coupling to the gear. Install the clamp bolt and nut and torque to 35-45 ft-lb. On power steering units, install the pinch bolt into the flange and insulator assembly and torque to 28-35 ft-lb.
2. Install the back-up light switch on the column.
3. Position the upper column support brackets and install the four retaining bolts finger tight.
4. Install and tighten the four column bracket-to-support bracket bolts and nuts.
5. Position the rubber seal and plate assembly to the dash panel.
6. Position the steering column support bracket to the plate studs and install the five nuts. Install the column to the support bracket clamp with the bolt and nut.
7. Connect the shift rods to the shift levers and install new retaining clips.
8. Position the trim cover to the instrument panel and install the four retaining screws.
9. Install the steering wheel on the steering shaft. The gap between the lower edge of the steering wheel hub and the steering column should be .03 to .06 inch. The column should be loosened, if necessary, to obtain this specification.
10. Install the horn ring and the safety pad with its two screws.
11. Connect the back-up light and ignition switch wire connector.
12. Start the engine and check the shift operation.

SHIFT TUBE

Removal and Installation

1. Working from under the instrument panel, disconnect the ignition switch wire connector.
2. Remove the steering wheel, bushing and the spring from the steering column.
3. Carefully remove the pin that secures the selector lever to the hub and remove the lever.
4. If working on a vehicle equipped with an automatic transmission, remove the neutral start switch from the shift tube.
5. Loosen the two flange attaching nuts enough to apply pressure on them (toward the center) to release the bolt heads from the steering column tube.
6. Carefully work the flange and selector hub and wires over the upper end of the steering shaft.
7. Slip the shift tube out of the steering column.
8. Apply lubricant to each end of the new shift tube.
9. Slip the shift tube into the upper end of the steering column making sure that the lower end of the tube engages shift lever or levers.
10. Place the selector lever hub and flange on the steering column tube and carefully pull the wires downward into place.
11. Engage the flange attaching bolt heads into the steering column tube and tighten the two nuts.
12. Place the steering shaft bushing and spring on the steering shaft and install the steering wheel.
13. If working on a vehicle equipped with an automatic transmission, install the neutral start switch actuator.
14. Connect the ignition switch wire connector.
15. Adjust the shift rods as required.

PART 13-07 Steering Column-Floor Mounted Shift Control

Applies to F-, B-, C-, CT-, L-, LT-, LTS-, W- and WT-Series (500 and up) Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
ADJUSTABLE COLUMN BRACKET		INTERMEDIATE STEERING SHAFT

		Description	07-01
Removal and Installation	07-05	Disassembly and Assembly	07-06
		Removal and Installation	07-04

DESCRIPTION

STEERING COLUMN

The F-B-500-7000, C-CT-Series and W-WT-9000 trucks are equipped with steering columns (Figs. 1, 2 and 3) which do not have shift controls. Shift controls on these vehicles are floor mounted.

The L-Series trucks are equipped with unique steering columns which, as an option, can be adjusted fore and aft controlled by a manual lever. The column has a column assembly and an intermediate shaft which connects to the steering gear (Fig. 4). These trucks also have floor mounted shift controls.

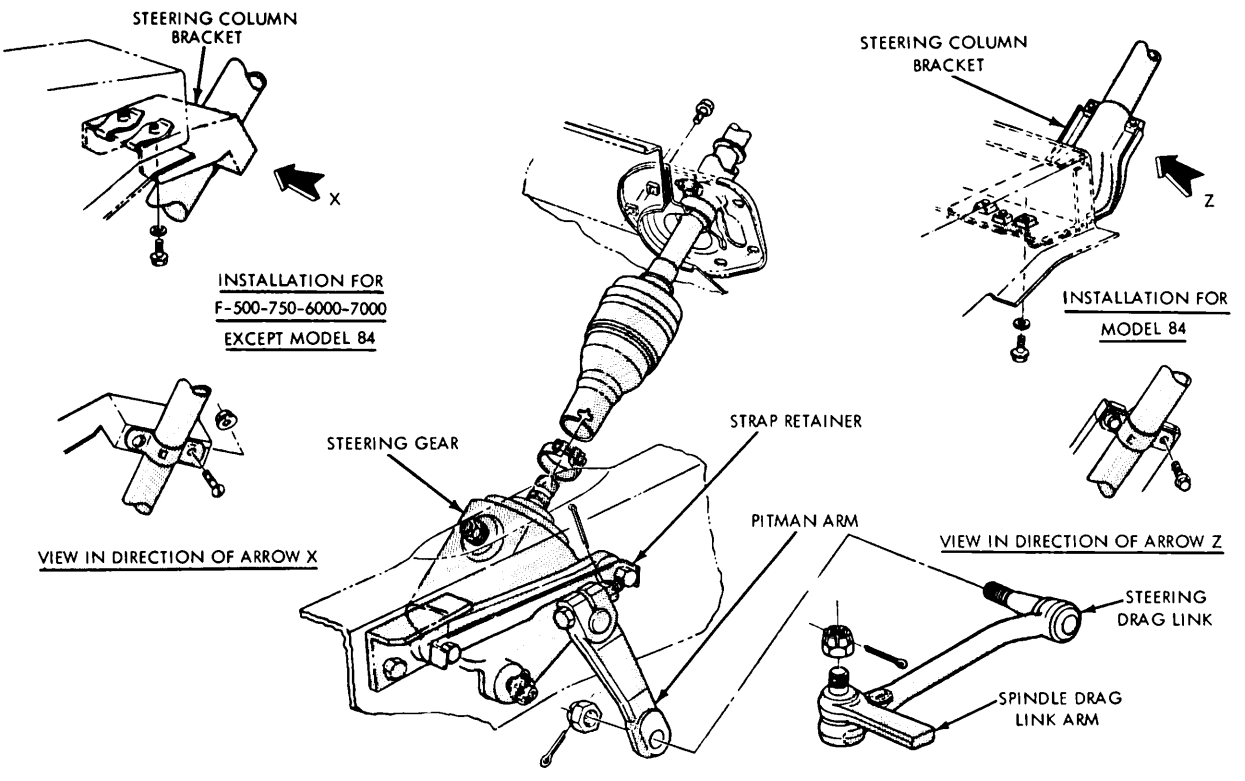

FIG. 1 Steering Column Installation—F-B-500-750, F-B-6000-7000 Attachment (Manual Steering)—Power Steering Similar Except for Shaft-to-Gear

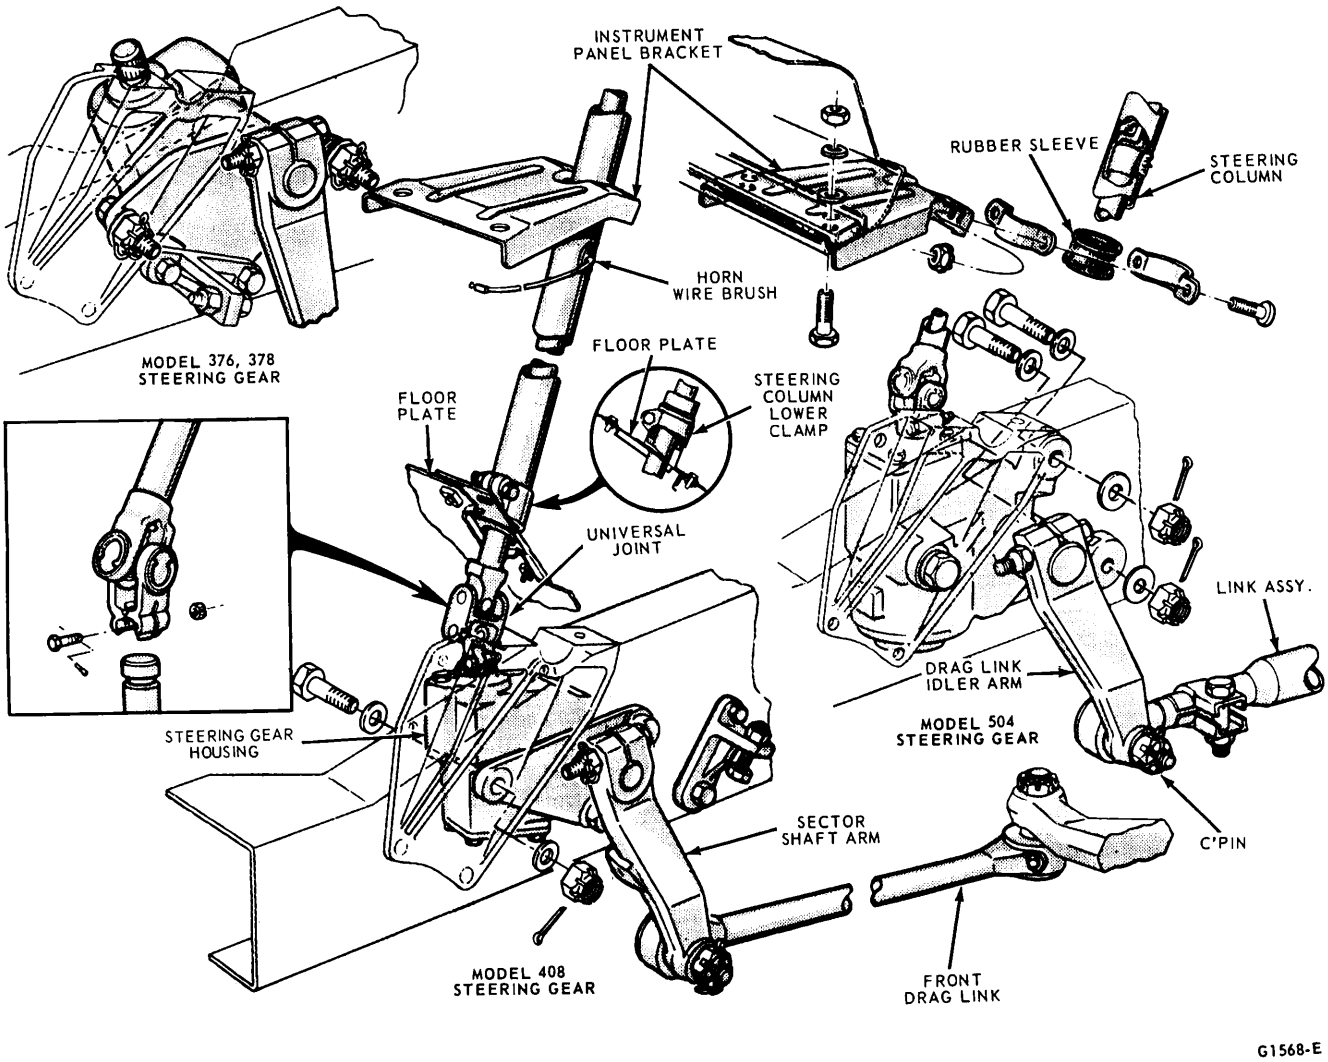

FIG. 2 Steering Column Installation—C-Series

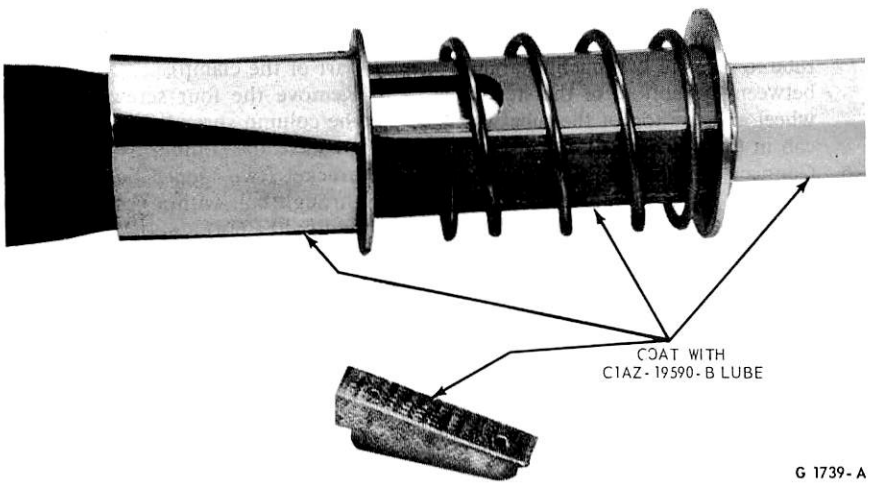

FIG. 3 Steering Column Installation—W-WT-Series

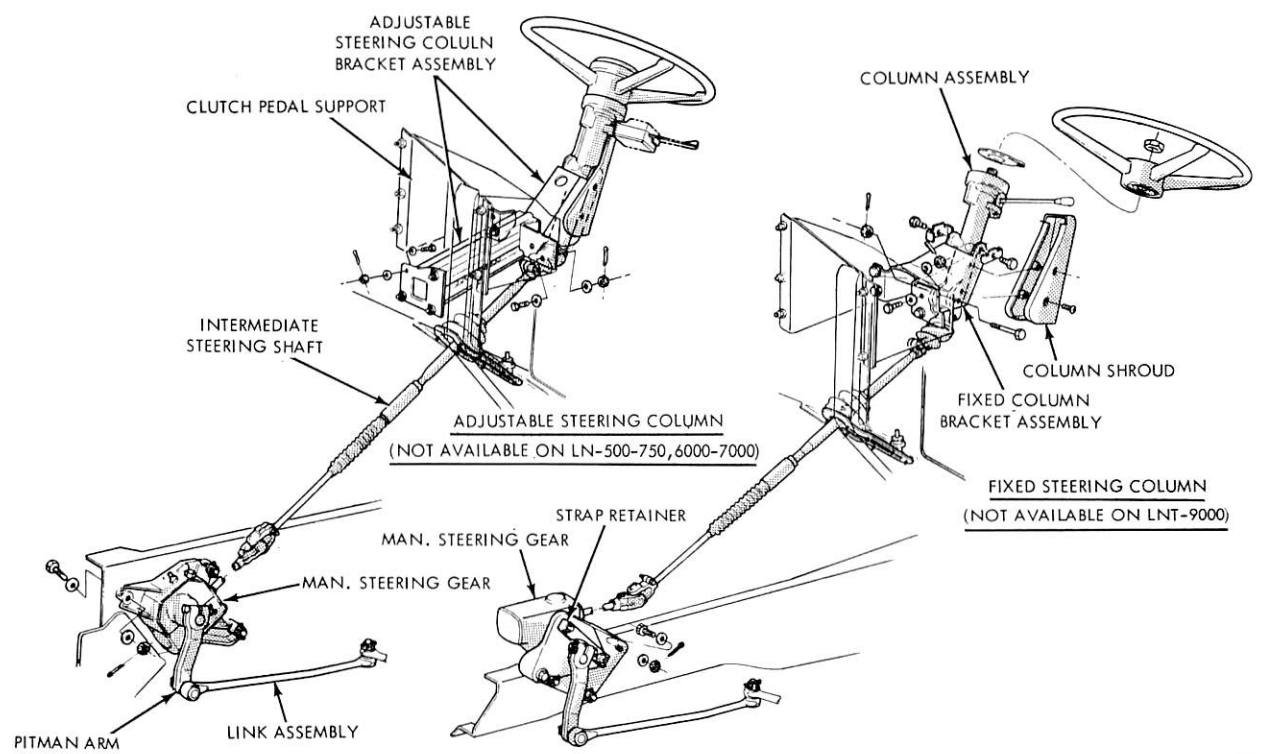

FIG. 4 Steering Column Installation—L-Series

REMOVAL AND INSTALLATION

STEERING COLUMN

F-B-500-750, F-B-6000-7000, F-600 (4 X 4)

Removal

1. Disconnect the horn, turn signal and back-up light wires.
2. Remove the steering wheel.
3. Remove the two screws or bolts retaining the steering column to the instrument panel bracket (Fig. 1).
4. Remove the seven screws retaining the column retainer assembly to the floor pan.
5. Disconnect the steering column from the steering gear.
6. Lift the column out of the vehicle.

Installation

1. Position the column in the vehicle.
2. Align the column to the steering gear. On units with power steering, make certain the flexible coupling is flat when installation is complete. A new shaft-to-gear attaching bolt should be installed to align with the annular groove in the steering gear stub shaft.
3. Install the two screws or bolts retaining the steering column to the instrument panel bracket.
4. Install the seven screws retaining the column retainer to the floor pan.
5. Install the steering wheel using a new nut and torque to specification.
6. Connect the horn, turn signal and back-up light wires.

C-CT-SERIES

Removal

1. Disconnect the horn, turn signal and back-up light wires (and other optional equipment attached to the column).
2. Remove the steering wheel as described in Part 13-34.
3. Remove the two clamp bolts retaining the steering column to the instrument panel bracket (Fig. 2).
4. Remove the cotter pin, nut and bolt retaining the shaft assembly to the steering gear.
5. Remove the four bolts retaining the flange and retainer assembly to the floor pan.
6. Lift the column out of the vehicle.

Installation

1. Position the column in the vehicle.
2. Align the shaft assembly to the steering gear and install the bolt, nut and cotter pin. Make certain the bolt is torqued and aligned with the annular groove in the gear stub shaft.
3. Install the four bolts retaining the flange and retainer assembly to the floor pan.
4. Install the two clamp bolts retaining the steering column to the instrument panel. Make certain the shaft is centered in the tube prior to installing the steering wheel.
5. Install the steering wheel as described in Part 13-34. Adjust the tube to provide 1/16 inch clearance between the bottom of the steering wheel and the top of the tube with cab in the down position.
6. Connect the horn, turn signal and back-up light wires (and other optional equipment attached to the column).

W-WT-9000

Removal

1. Disconnect the horn, turn signal and back-up light wires (and other optional equipment attached to the column).
2. Remove the steering wheel as described in Part 13-34.
3. Remove the four screws retaining the shroud to the clamp assembly.
4. Remove the two bolts retaining the steering column clamp to the instrument panel (Fig. 3).
5. Remove the three bolts retaining the bracket to the floor pan.
6. Remove the bolt, washer and nut retaining the steering shaft assembly to the steering gear.
7. Lift the column out of the vehicle.

Installation

1. Position the column in the vehicle.
2. Attach the steering shaft assembly to the steering gear with the bolt, washer and nut. Make certain the bolt is aligned in the steering gear shaft annular groove.
3. Install the three bolts retaining the bracket to the floor pan.
4. Install the two bolts retaining the steering column clamp to the instrument panel.
5. Install the shroud with the four screws to the clamp assembly.
6. Install the steering wheel as described in Part 13-34.
7. Connect the horn, turn signal and back-up light wires (and other optional equipment attached to the column).

L-SERIES

Removal

1. Disconnect the battery.
2. Remove the steering wheel from the column.
3. Disconnect the directional flasher control at the quick disconnect terminals and remove the air brake control (if so equipped) from the column.
4. The upper steering shaft is attached to the intermediate shaft with a clamp and lock tab assembly, bolt and nut (Fig. 14). Bend the lock tab to remove the nut (the lock tab is part of the clamp).
5. Remove the four screws retaining the column shroud (Fig. 4).
6. Remove the column from the dash bracket (two tapped bolts and one through bolt with a castellated nut and cotter pin).
7. Remove the column from the vehicle.

Installation

1. Position the column in the vehicle and attach the column to the dash bracket with the two tapped bolts and the one through bolt with a castellated nut and cotter pin.
2. Attach the shroud with the four retaining screws.
3. Attach the upper steering shaft to the intermediate shaft using a new clamp assembly. The clamp bolt must be aligned with the annular groove in the intermediate shaft (Fig. 14). Torque the nut to 31-42 ft-lb and bend the lock tab against a nut flat.
4. Connect the directional flasher control and the air brake control (if so equipped).
5. Install the steering wheel using a new nut and set screw as described in Part 13-34.
6. Connect the battery ground cable.

ADJUSTABLE COLUMN BRACKET

L-SERIES

Removal

1. Remove the four screws retaining the shroud to the steering column.
2. Disconnect the directional flasher control at the quick disconnect terminal.
3. Bend the lock tabs up and remove the two upper steering column retaining bolts.
4. Remove the lower column retaining through bolt. Drop the column down.
5. Remove the release cable clamp from the steering column and the air line retaining bracket (if so equipped).
6. With a helper, remove the four

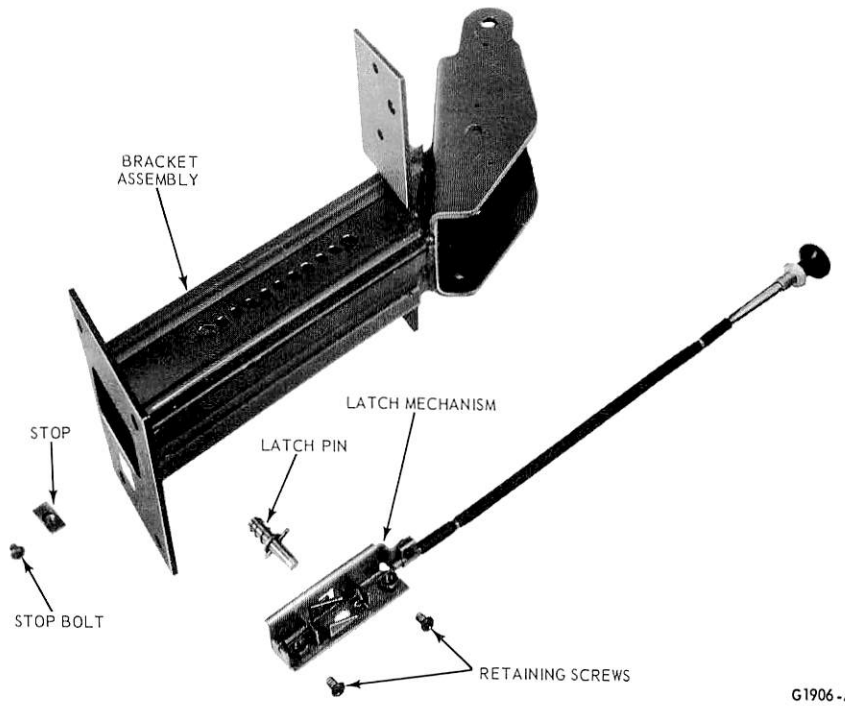

FIG. 5 Adjustable Bracket Disassembled

steering wheel bracket retaining screws and remove the bracket.
7. Remove the two dash panel-to-steering column bolts.
8. Remove the three steering column bracket-to-dash panel retaining screws.
9. Position the adjustable column bracket all the way forward and remove it from the vehicle.

Installation

1. Position the adjustable column bracket in the vehicle.
2. Install the three steering column bracket-to-dash panel retaining screws.
3. Install the two dash panel-to-steering column retaining bolts.
4. With a helper, install the four steering wheel bracket retaining screws.
5. Install the release cable clamp to the steering column.
6. Install the air line retaining bracket (if so equipped).
7. Position the steering column up and install the lower column retaining through bolt.
8. Install the two upper retaining bolts and bend the lock tabs down onto the bolts.
9. Connect the directional flasher control at the quick disconnect terminal.
10. Install the four screws retaining the shroud to the steering column.
11. Check the column positioning operation.

ADJUSTABLE COLUMN LATCH MECHANISM

L-SERIES

Removal

1. Remove the Allen stop bolt and stop from the lower end of the adjusting bracket.
2. Release the inner tube of the bracket and move the inner tube forward until the lower latch plate retaining screw is visible through the last (larger) hole in the bracket outer tube. Remove the retaining screw.
3. Now move the inner tube in the opposite direction to expose the other retaining screw in the rearward larger hole. Remove that retaining screw.
4. Move the inner tube forward again until the latch pin is centered in the last (larger) hole in the bracket outer tube.
5. With a screwdriver, turn the latch pin 90 degrees clockwise to release it from the latch mechanism. Work the latch pin free of the collar of the boss (located in the inner tube) and remove the pin and mechanism through the lower end of the bracket (Fig. 5).

Installation

1. **Do not disturb the cable retaining clamp screw (preset in manufacture).**
2. Lay the latch pin in the latch mechanism as shown in Fig. 6.
3. Carefully insert the pin and latch mechanism into the lower end of the bracket (Fig. 7), working the slotted end of the pin through the elongated hole in the inner tube and the larger hole in the outer tube. The pin, when properly located, will slip up and over the boss collar and seat.
4. With the screwdriver, depress the latch pin and move the inner tube rearward until the lower retaining screw can be installed and tightened through the larger, lower hole.
5. Again move the inner tube rearward until the other retaining screw can be installed and tightened through the larger, rearward hole.
6. With a screwdriver, turn the latch pin 90 degrees counterclockwise to engage it to the latch mechanism.
7. Install the Allen stop bolt and stop in the lower end of the adjusting bracket.

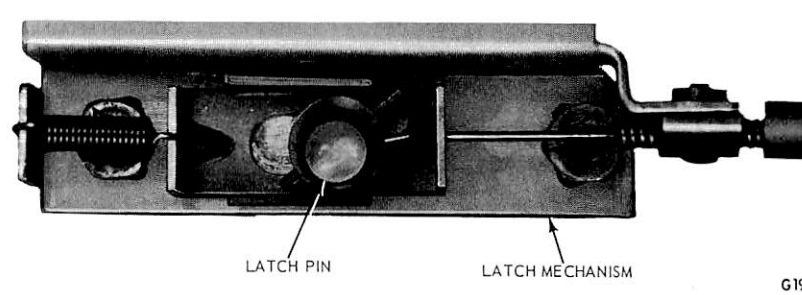

FIG. 6 Latch Pin Placement

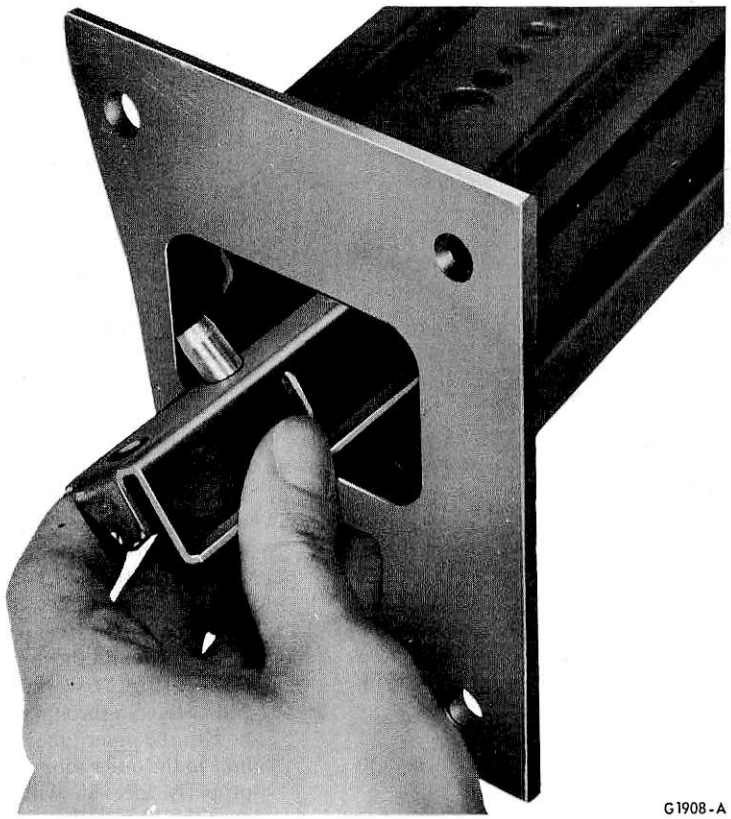

FIG. 7 Installing Pin and Latch Mechanism

DISASSEMBLY AND ASSEMBLY

STEERING COLUMN

L-SERIES

Disassembly

1. Remove the cotter pin from the adjusting nut at the lower end of the column.
2. Loosen the adjusting nut.
3. Remove the snap ring at the upper end of the column (Fig. 8).
4. Remove the inner shaft from the column tube by carefully striking the top of the shaft with a plastic mallet.

Assembly

1. Insert the inner shaft into the column tube taking care not to damage the upper bearing.
2. Install the snap ring at the upper end of the column.
3. Apply 13-18 ft-lb torque to the adjusting nut while rotating the shaft to seat the bearings.
4. Back off the nut 1/2 turn and retorque to 3-7 ft-lb. The steering shaft rotating torque should be 10-15 in-lb. Install the adjusting nut cotter pin.

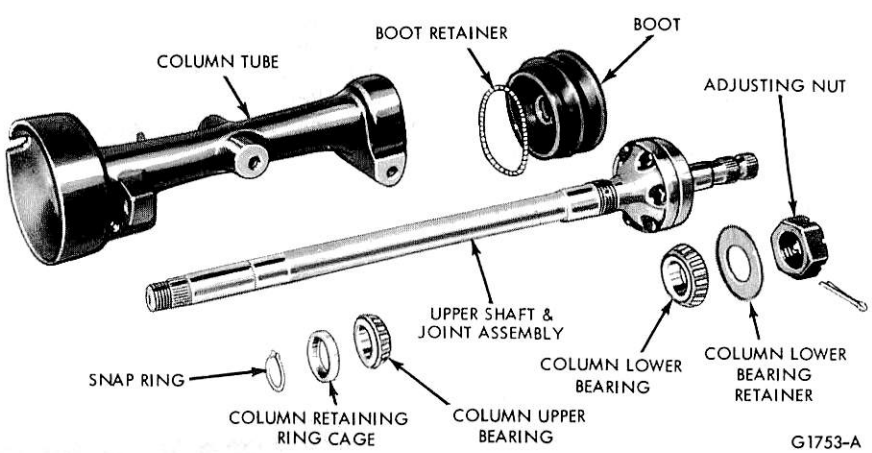

FIG. 8 Steering Column—L-Series—Disassembled

INTERMEDIATE STEERING SHAFT

L-SERIES

Servicing of this component (performed with the assembly removed from the vehicle) normally will only be required if the coupling assembly has excessive lash or fails to telescope in and out under normal operation.

This shaft is a coupling assembly with a hex shaft telescoping into a reduced hexagonal cross section tube. The clearance between the shaft and tube is automatically compensated by a wear pad, an adjusting can, a spring, a

preset retainer and the spring pre-load eliminating lash (Fig. 9).

Disassembly

1. Remove the stop bolt from the end of the hex shaft.
2. Pull the hex shaft completely out of the tube and boot (Fig. 10).
3. Remove the boot from the tube assembly.
4. Remove the rubber insert located over the enlarged round tube section (Fig. 10).
5. Pull back on the adjusting can, compressing the spring. Remove the wear pad from the adjusting can slot (Fig. 11).
6. Thoroughly clean the shaft, tube assembly, boot and wear pad with a non-abrasive solution.
7. Inspect all parts for excessive wear and replace where applicable.

Assembly

1. Repack the hexagonal shaft and the inside surface of the reduced hexagonal end of the tube with C1AZ-19590-B lube.
2. Coat the spring area and the surface around the adjusting can with C1AZ-19590-B lube (Fig. 12).
3. Insert the shaft in the tube. The shaft should stroke freely at a maximum pull load of 3 1/2 lbs. If the load exceeds this specification, replace the required parts.
4. Lubricate the wear pad and insert it in the slot by compressing the adjusting spring.
5. Stroke the shaft in the tube. It should stroke freely at a maximum pull load of 12 lbs. If the load exceeds this specification, replace the required parts.
6. Insert the rubber insert to the position shown in Fig. 13.
7. Slip the boot with the convoluted end towards the male serrations over the shaft. Then slip the smooth end of the boot over the spring and adjusting can (Fig. 14).
8. Assemble the stop bolt in the end of the hex shaft. Torque to 22-20 ft-lb.

PART 13-22 Steering Linkage—Power Gear/ Power Cylinder

Applies To F-600 (4x4), F-750-7000, LN-750-7000 (with 9000 lb. axles), LNT-LT-LTS-800-9000 (with 16, 18, 20000 lb. axles), W-WT-9000 Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
POWER CYLINDER		POWER CYLINDER SEAL	
Disassembly and Assembly	22-04	Removal and Installation	22-03
Removal and Installation	22-01		
POWER CYLINDER HOSE SEAT		STEERING LINKAGE	
Removal and Installation	22-03	Description	22-01

DESCRIPTION

STEERING LINKAGE

Various types of power steering systems are optional equipment on some medium, heavy and extra heavy trucks. The F-600 (4 x 4), F-750-7000, LN-750-7000 vehicles with 9000 lb front axles, all LNT-LT-LTS-800-900, 8000-9000 units with 16000, 18000 and 20000 lb. front axles and all W-WT-9000 trucks use a power steering gear coupled with a power cylinder (Figs. 1 through 5).

REMOVAL AND INSTALLATION

When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

See Group 50 for Hoisting instructions. For Removal and Installation of the steering gear, refer to Groups 13-43 and 13-44, under Removal and Installation. Steering wheel replacement procedure is described in Group 13-34, under Removal and Installation.

POWER CYLINDER

Removal

1. Make certain the pressure and return hoses are properly identified (front and rear) to insure proper port connections during installation.
2. Disconnect the hoses from the cylinder and fasten them in a raised position.
3. On F-LN-Series, back out the cylinder plug on the piston rod end of the cylinder until it is possible for the ball stud to clear the cylinder. The ball stud should remain on the tie rod (Fig. 1).

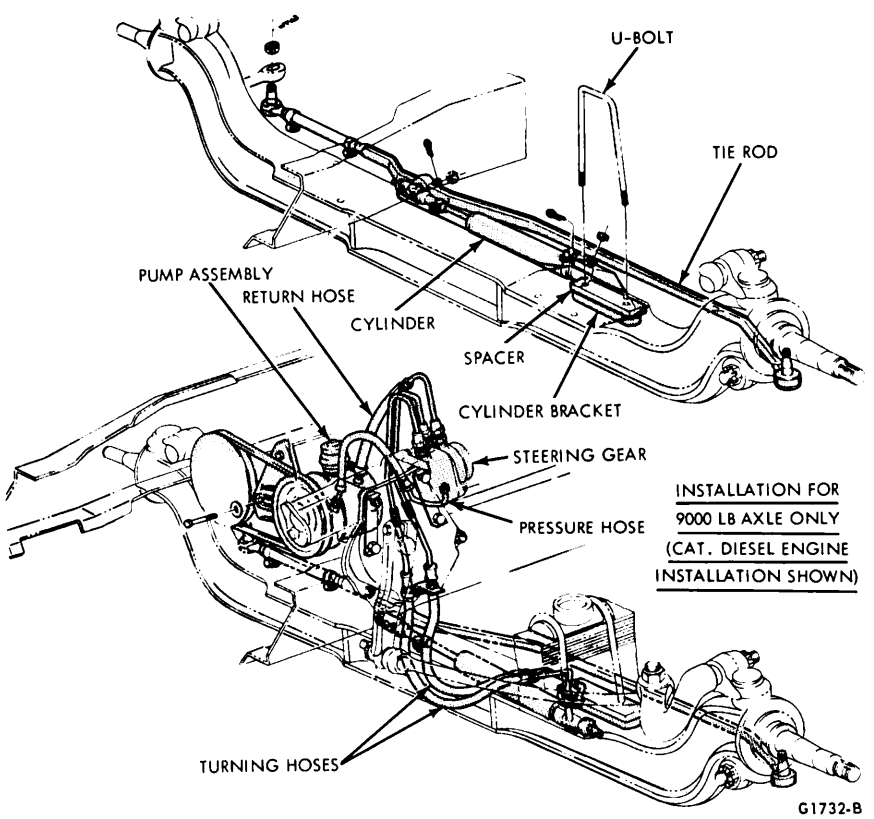

FIG. 1 Power Steering Installation—LN-750 W/9000 lb. Axle (F-750 Similar)

On LT-LNT-LTS-Series, back out the cylinder plug at the forward end of the cylinder until it is possible for the ball stud to clear the cylinder. The ball stud should remain in the side rail bracket (Fig. 2).

On F-600 (4 x 4) vehicles, back out the cylinder plug on the anchored end of the cylinder until it is possible for the ball stud to clear the cylinder. The ball stud should remain with its anchoring bracket (Fig. 4).

On W-Series, the ball stud must be removed from the pitman arm exercising care not to damage the attaching surfaces of the stud (Fig. 5).

4. On all units, the opposite end of the cylinder must be disconnected by dropping the ball stud from the bracket (steering arm on F-600 4 x 4-LT-LNT-LTS-Series). Again, care should be taken to prevent harming the seal or threads of the stud.

Installation

When repairing or replacing a cylinder, remember that the ball stud attachment is adjustable on all power cylinders and, using this means, be certain that the cylinder does not bottom in a full left or full right turn.

1. On all units, connect the anchored end of the cylinder to its mounting bracket (steering arm on F-600 4 x 4-LT-LNT-LTS-Series) with the ball stud. Install the nut and torque to 50-70 ft-lb (110-150 ft-lb on LT-LNT-LTS-W-WT-Series). If necessary, advance to the next castellation and install the cotter pin.
2. On W-Series, connect the piston rod ball stud to the pitman arm and install the nut. Torque to 110-150 ft-lb and, if necessary, advance the nut to the next castellation to insert the cotter pin (Fig. 5).

On F-600 (4 x 4) vehicles, insert the ball stud on the anchoring bracket into the rearward end of the cylinder. Install the cylinder plug and torque to specification (15 ft-lb). Back off to the nearest castellation and install the cotter pin (Fig. 4).

On LT-LNT-LTS-Series, insert the

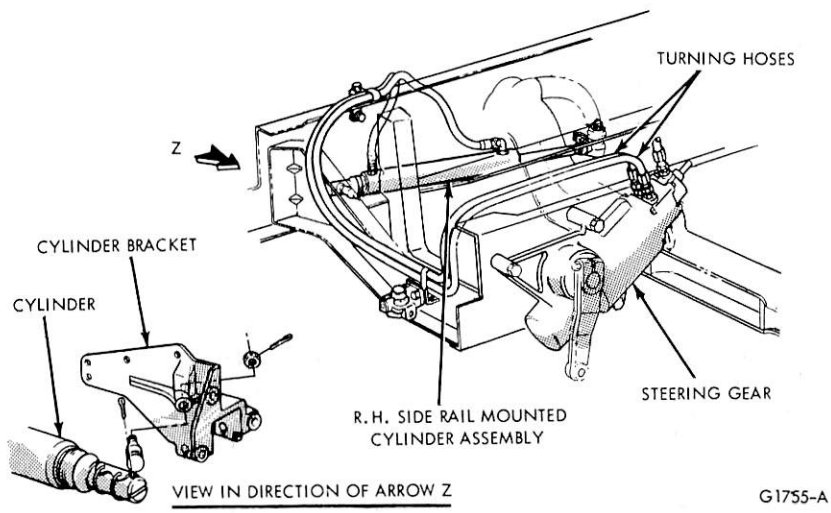

FIG. 2 Power Steering Installation—LT-LNT-LTS—Series W/16000, 18000, 20000 lb. Axles

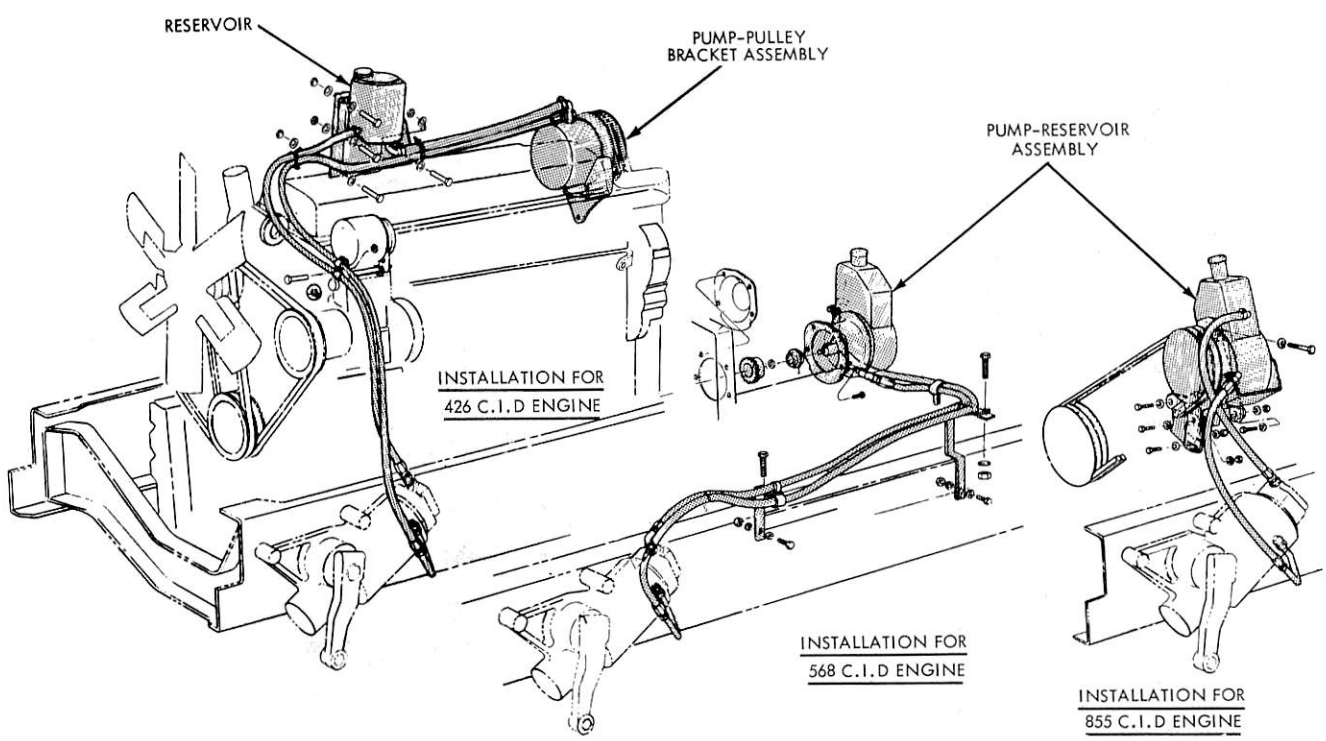

FIG. 3 Power Steering Pump Installation— L-LT-LTS-LN-LNT-Series with Diesel Engines

ball stud on the side rail bracket into the forward end of the cylinder. Install the cylinder plug and torque to specification (40-50 ft-lb). Back off a 1/8 minimum to 5/8 maximum turn for cotter pin installation (Fig. 2).

On F-LN-Series, insert the ball stud on the tie rod into the piston rod end of the cylinder. Install the cylinder plug and torque to specification (15 ft-lb). Back off to the nearest castellation for cotter pin installation (Fig. 1).

3. Connect the two hoses to their **proper** ports. Fill the fluid reservoir to specification with automatic transmission fluid.
4. Start the engine and run it at idle speed for about two minutes to warm the fluid in the power steering system.
5. Turn the steering wheel all the way to the left and right several times, and check the system for fluid leak. Check the reservoir for proper fluid level. Fill if required.
6. Increase the engine speed to about 1000 rpm, and turn the steering wheel all the way to the left and right several times. Do not hold the wheels against the stops.
7. Stop the engine, and check the power cylinder and hose connections for fluid leaks. Correct the cause of any leaks.

POWER CYLINDER SEAL

W-WT-SERIES

Removal and Installation

The W-WT-Series power cylinder cannot be disassembled. Only the oil seal and snap ring can be replaced.

1. Carefully clamp the power cylinder in a vise in a manner to prevent distortion, and remove the snap ring from the end of the cylinder.
2. Remove as much fluid from the cylinder as possible by stroking the piston rod in and out. Apply air pressure to the retracting port on the cylinder to blow out the seal.
3. After lubricating a new seal with automatic transmission fluid, position it on the piston. Install the seal with a suitable deep socket.
4. Install the retaining snap ring with the sharp edge facing out.

POWER CYLINDER HOSE SEAT

W-WT-SERIES

Removal and Installation

If any of the cylinder hose seats need replacement, use the following procedures:

1. Tap the existing hole in the hose seat. Use a 3/8 inch starting tap for the large hose seat and a 1/4 inch starting tap for the small seats. **Be sure to remove all metal chips from the hose seat port after tapping.**
2. Place a nut and large flat washer on a bolt of the same size as the tapped hole. The washer must be large enough to cover the hose seat port.
3. Thread the bolt into the tapped hole,

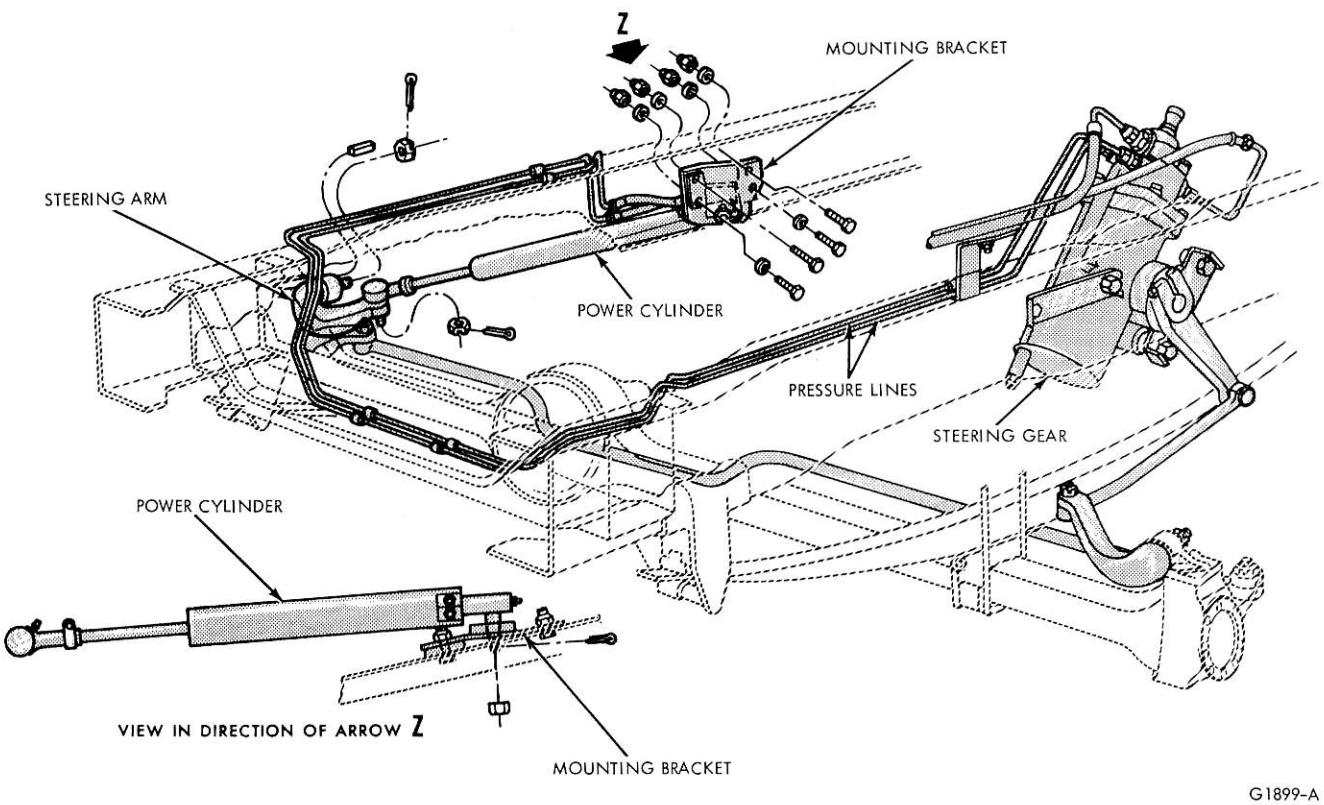

FIG. 4 Power Steering Installation—F-600 (4 x 4)

and turn the nut to remove the hose seat.

4. Place a new hose seat in the port, and thread a bolt of the same size as the port into the port. Tighten the bolt enough to bottom the seat in the port.

DISASSEMBLY AND ASSEMBLY

The procedures given in Part 13-34, under Disassembly and Assembly also apply to vehicles equipped with a power steering.

POWER CYLINDER

Disassembly

Handle all parts with care. Clean all parts by washing in a suitable solvent and blow dry with compressed air.

1. Drain the oil from the power cylinder by moving the piston rod (Figs. 6 and 7) in and out from one extreme end of its travel to the other.
2. Remove the retaining bolts on the end plate and remove the end plate.
3. Remove the cylinder retaining ring by pushing the cylinder into the cylinder barrel approximately 1/4 inch and compressing the retaining ring. This is accomplished by inserting a punch through the knock out hole in the cylinder shell barrel.
4. Pull out the piston rod (Figs. 6 and 7) to expose the integral parts of the cylinder shell.
5. Remove the piston rod nut from the piston end of the rod. **The rod should be held at the two wrench flats near the outer thread end to prevent damage to the rod OD finish.**
6. Slide off the piston.
7. Remove the cylinder gland from the piston rod by sliding it off the piston end of the piston rod.
8. With the cylinder gland removed from the rod, remove the sealing parts in the following order: (as in Fig. 6) the outer retaining ring, the outer retaining washer, the oil seal, the inner retainer washer, the inner retaining ring, the leather back-up washer and the inner O-ring; (as in Fig. 7) the scraper, the inner retaining ring, and the seal.
9. Remove the O-ring and back-up ring from the OD of the cylinder gland.

Assembly

1. Lubricate all seals and O-rings with light oil before assembling.
2. To the inside of the cylinder gland (as in Fig. 7), assemble the seal, the inner retaining ring and the scraper with the lip toward the outside of the cylinder.
3. On cylinders shown in Fig. 6, assemble the O-ring, the leather back-up washer, the inner retaining ring, the inner retaining washer, the oil seal (with the lip toward the outside of the cylinder), the outer

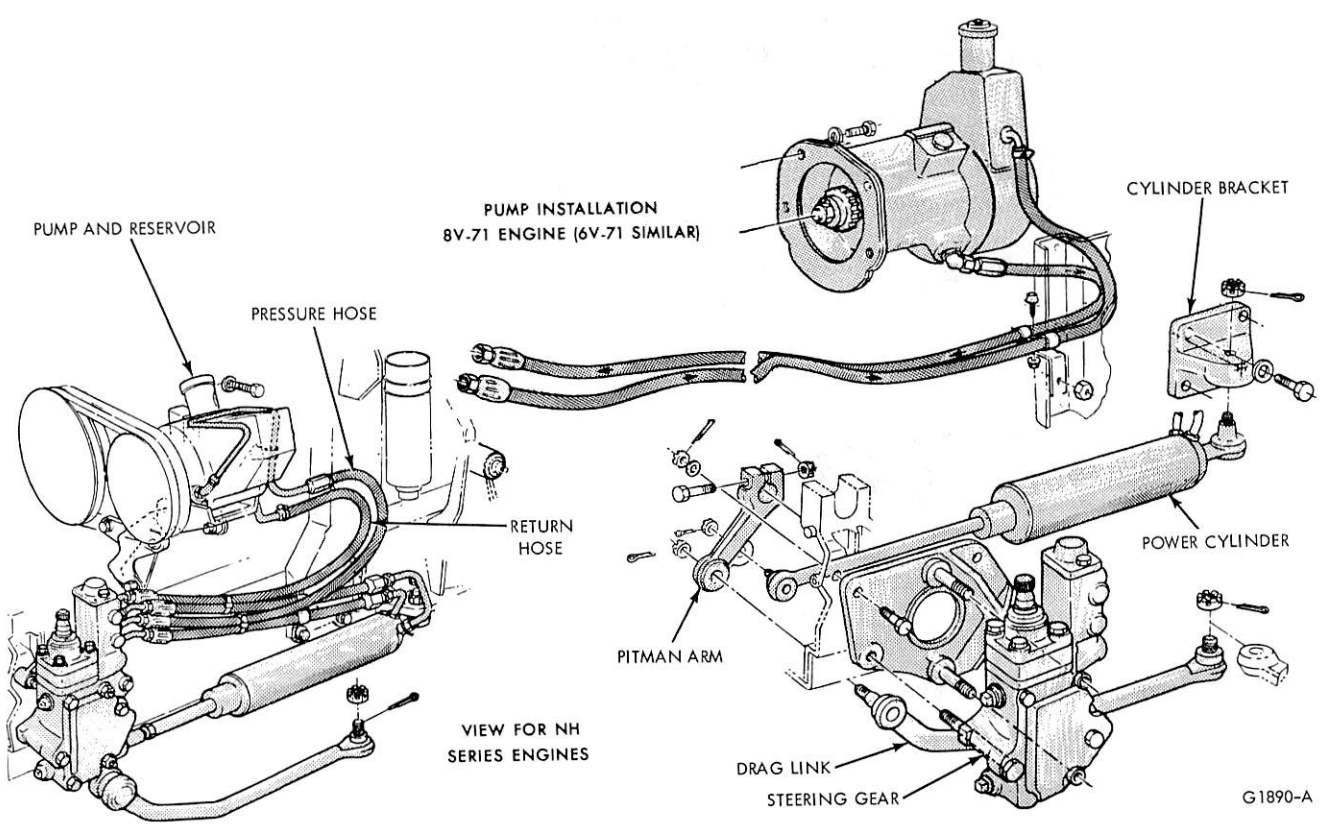

FIG. 5 Power Steering Installation—W-WT-9000 Typical

retaining washer and the outer retaining snap ring.

4. Install the back-up ring and the O-ring to the OD of the cylinder gland. To prevent damage to the rod oil seal, carefully slide the cylinder gland over the piston end of the piston rod toward the threaded end.
5. Secure the piston to the end of the piston rod with the piston rod nut. Torque the nut to specification (30-35 ft-lb, F-600 4 x 4 and F-LN-750-7000 with 9000 lb. axle; 60-65 ft-lb, LTS-Series with 16, 18, 20000 lb. axles; 100-125 ft-lb, LT-LNT-Series with 16000 lb. axle).
6. Push the piston rod assembly into the cylinder shell approximately half way. Slide the cylinder gland into the cylinder shell taking care not to damage the O-ring as it moves past the retaining ring groove in the end of the cylinder shell.
7. Lock the cylinder in place by installing the cylinder retaining ring in the cylinder shell groove.
8. Check for binding by moving the piston rod through its full travel several times.
9. Assemble the end plate with its retaining bolts.

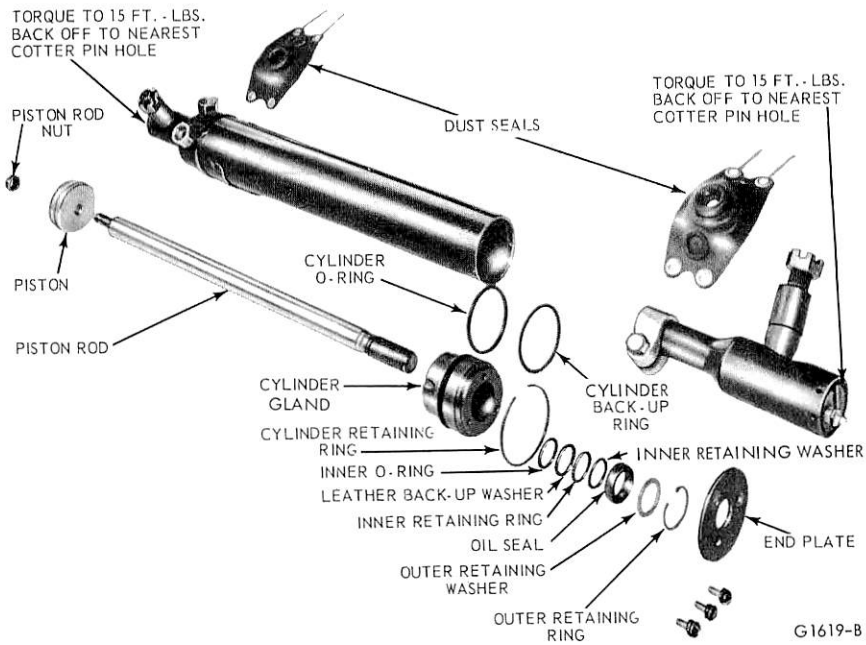

FIG. 6 Power Cylinder Disassembled—F-LN-750-7000 W/9000 Lb. Axle (F-600 4 x 4 and LTS W/16, 18 and 20000 Lb. Axles Similar)

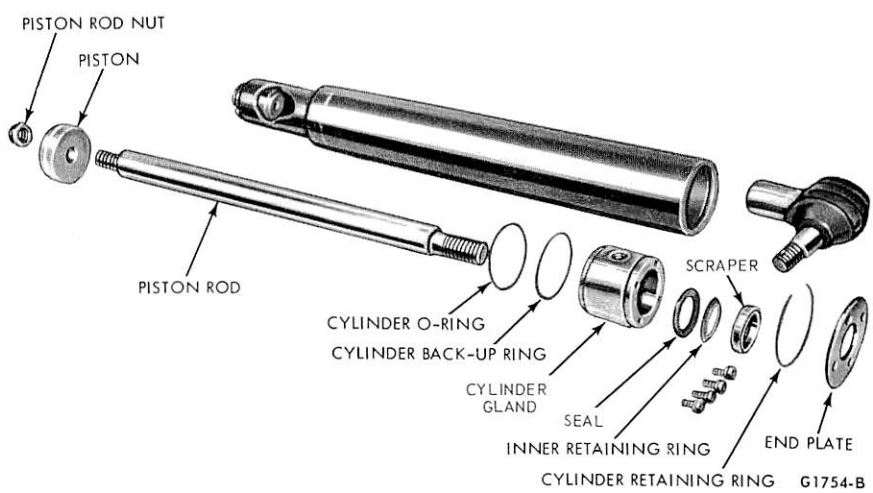

FIG. 7 Power Cylinder Disassembled LT-LNT-Series W/16000 Lb. Axle

PART 13-23 Steering Linkage—Power Cylinder/Control Valve

Applies To C-CT Series, Econoline Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page

		Removal and Installation	23-04

DESCRIPTION

STEERING LINKAGE

The C-CT-Series and Econoline are equipped with a separate power cylinder and a separate control valve with no power gear included in the linkage system (Figs. 1, 2 and 3).

ADJUSTMENTS

The procedures given in Parts 13-33 and 34 under Adjustments also apply to vehicles equipped with power steering.

PITMAN ARM STOPS

ECONOLINE

1. Loosen the lock nut on both pitman arm stops (Fig. 3) and turn the adjusting screws inward several turns.
2. Turn the steering wheel to the right, until the right spindle steering arm contacts the stop.
3. Adjust the forward pitman arm stop outward until it contacts the pitman arm. Tighten the lock nut.
4. Turn the steering wheel to the left, until the left spindle steering arm contacts the stop.
5. Adjust the rearward pitman arm stop outward until it contacts the pitman arm. Tighten the lock nut.

REMOVAL AND INSTALLATION

When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

See Group 50 for Hoisting instructions. For Removal and Installation of the steering gear and steering wheel, refer to Parts 13-33 and 13-34 under Removal and Installation.

POWER CYLINDER

C-SERIES

Removal

1. Make certain the pressure and return hoses are properly identified (front and rear) to insure proper port connections during installation.
2. Disconnect the hoses from the cylinder and fasten them in a raised position.
3. On C-900 (with a 9.76 frame), CT-800 and CT-900 (with 9000, 12000 or 15000 lb. front axles) models, remove the nut and mounting bolt retaining the piston rod eye to the

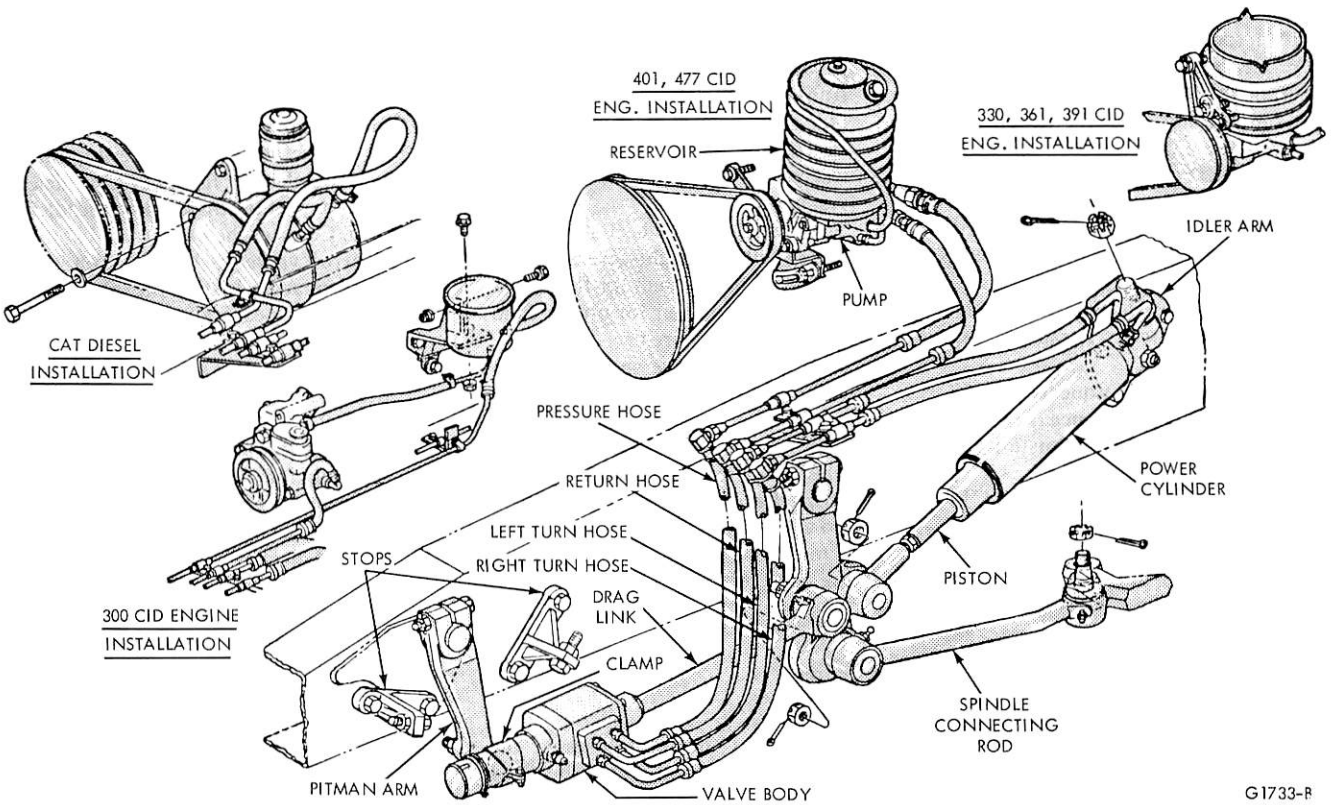

FIG. 1 Power Steering Installation C-500-800,900 (9.50 Frame),C-6000-8000

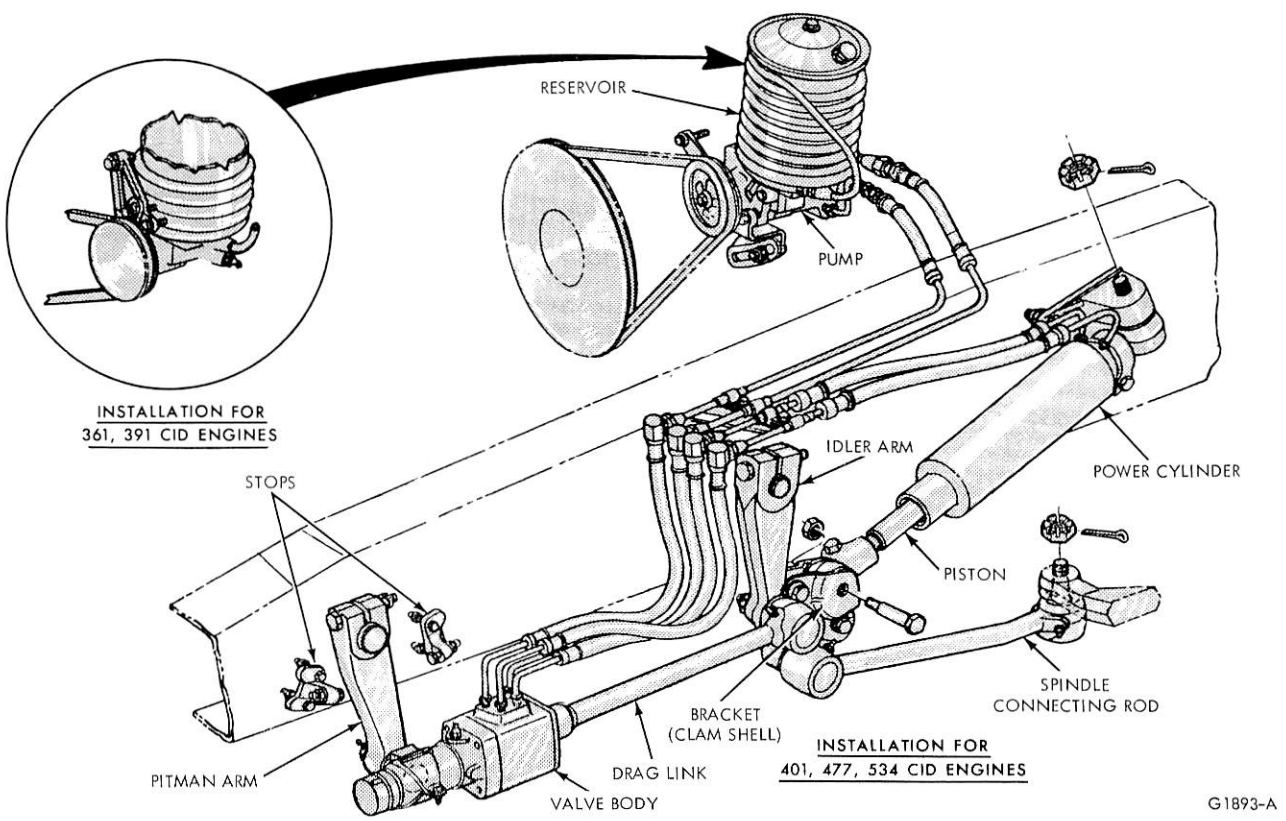

FIG. 2 Power Steering Installation C-900 (9.76 Frame), CT-800-900 (9000, 12000,15000 lb. Axles)

bracket (clam shell). Force the piston rod into the cylinder until the eye clears the bracket (Fig. 2).

On all other C models, remove the cotter pin and nut from the piston rod ball stud. Disconnect the ball stud from the idler arm (Fig. 1).

4. Remove the cotter pin and nut from the ball stud at the rear end of the cylinder, and remove the cylinder.

Installation

1. Position the anchored end of the power cylinder in its mounting bracket.
2. Install the nut and torque to 110-150 ft-lb. If necessary, advance the nut to its next castellation to install the cotter pin.
3. On C-900 (with a 9.76 frame), CT-800 and CT-900 (with 9000, 12000 or 15000 lb. front axles) models, pull the piston rod out of the cylinder until the piston rod eye is positioned between the holes in the bracket. Insert the mounting bolt through the bracket and eye. Install the nut and torque to specification (Fig. 2).

On all other C models, pull the piston rod out of the cylinder until the piston rod ball stud can be inserted into the idler arm. Install the nut and torque to 110-150 ft-lb. If necessary, advance to the next castellation to install the cotter pin (Fig. 1).

4. Connect the two hoses to their **proper ports. Fill the fluid reservoir to specification with automatic transmission fluid.**
5. Start the engine and run it at idle speed for about two minutes to warm the fluid in the power steering system.
6. Turn the steering wheel all the way to the left and right several times, and check the system for fluid leak. Check the reservoir for proper fluid level. Fill if required.
7. Increase the engine speed to about 1000 rpm, and turn the steering wheel all the way to the left and right several times. Do not hold the wheels against the stops.
8. Stop the engine, and check the power cylinder and hose connections for fluid leaks. Correct the cause of any leaks.

CONTROL VALVE

C-SERIES

Removal

1. Disconnect the four hoses at the control valve, and drain the fluid from the hoses.
2. Remove the plug from the forward end of the valve and disconnect the control valve from the stud on the pitman arm.
3. Disconnect the drag link from the idler arm and remove the valve and drag link (Figs. 1 and 2).

Installation

1. If necessary, install a new dust cover in the sector shaft arm. Position the valve and drag link in the vehicle and connect the drag link to the idler arm. Connect the forward end of the control valve to the stud on the pitman arm. Install the plug and torque to specification.
2. Connect the hoses at the valve.
3. Lubricate the two studs at the grease fittings.
4. Fill the fluid reservoir to the specified level with automatic transmission fluid.
5. Operate the engine at idle speed for about two minutes to warm the fluid. Check the fluid level, and check all hose connections for leaks.
6. Increase the engine speed to about 1000 rpm, and then turn the steering wheel to the left and right several times. Do not hold the wheels against the stops.
7. Stop the engine, place the front wheels in the straight ahead position and check the control valve and the hose connections for fluid leakage.
8. After correcting any fluid leaks, check the fluid level and refill the reservoir if necessary.

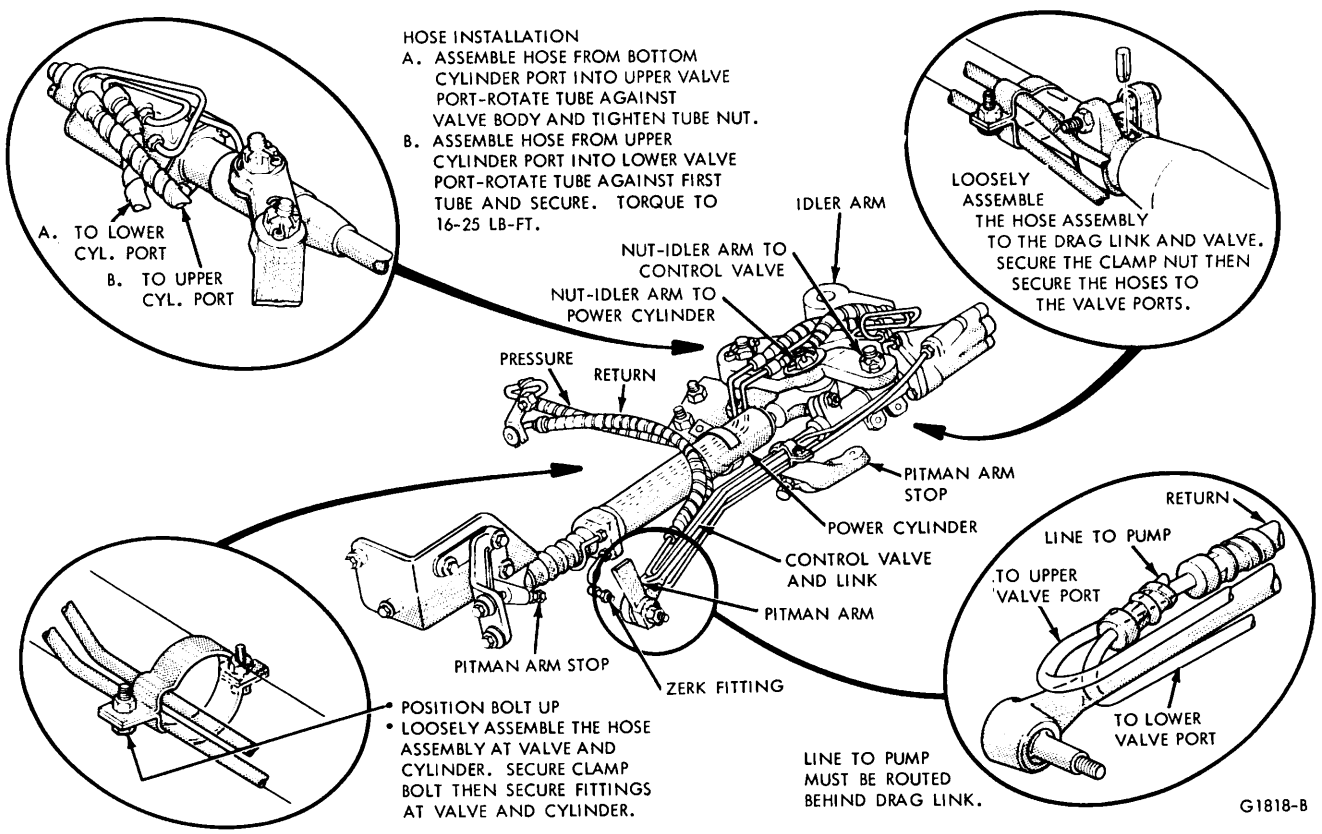

FIG. 3 Power Steering Installation Econoline

ECONOLINE

Removal

1. Remove the castellated nuts and cotter pins from the ball studs attaching the control valve and link to the pitman arm and the tie rods to the idler arm (Fig. 3).
2. Disconnect the control valve and link assembly from the pitman arm and tie rod assemblies from the idler arm.
3. Remove the pal nut, attaching nut, washer and insulator from the end of the power cylinder rod (Fig. 4).
4. Disconnect the two hoses attached to the power steering pump.
5. Remove the five bolts securing the idler arm bracket to the crossmember.
6. Remove the control valve and link, power cylinder, hoses, idler arm, and idler arm bracket as an assembly.

Installation

1. Thread the valve onto the link until the roll pin can be inserted into the notch behind the clamp. Torque 5/16 dia. clamp bolt to 15 ft-lb.
2. Connect the fluid lines to the control valve, and tighten all fittings securely. **Do not overtighten. 5/16 tube nut: 16-25 ft-lb, 3/8 tube nut: 20-30 ft-lb.**
3. Take the control valve and link, power cylinder, hoses, idler arm, idler arm bracket as an assembly and rest it on the engine crossmember.
4. Attach the idler arm bracket to the crossmember using the 7/16-14 x 1 1/2 grade nine bolts and hardened flat washers. Install one washer under the head of the bolt and one under the nut. Torque to 60 ft-lb.
5. Connect the two power steering hoses to the pump.
6. Attach the power cylinder to the front bracket (Fig. 4). Torque the 3/8-24 nut to 21 ft-lb and the pal nut to 45 in-lb.
7. Connect the control valve and link assembly to the pitman arm and the tie rods to the idler arm.
8. Install the castellated nuts and torque the tie rod to idler arm to 45 ft-lb (E-100-200), 60 ft-lb (E-300). All pitman arm nuts require 60 ft-lb. If necessary advance to the next castellation and insert and secure cotter pin.

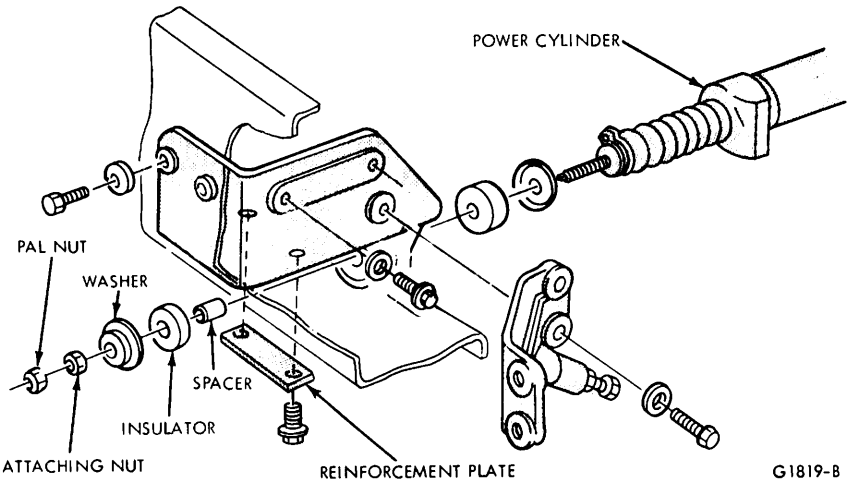

FIG. 4 Cylinder Rod Bracket Attachments

9. Connect the fluid lines to the pump, and tighten all fittings securely.
10. Fill the fluid reservoir with the specified fluid to the full mark.
11. Start the engine and run it at idle speed for about two minutes to warm the fluid in the power steering system.
12. Turn the steering wheel all the way to the left and right several times and check the system for fluid leaks.
13. Increase the engine speed to about 1000 rpm, and turn the steering wheel all the way to the left and right several times.
14. Stop the engine, and check the control valve and hose connections for fluid leaks. Correct the cause of any leaks.
15. Check the fluid level, and refill the reservoir if necessary.
16. Recheck the fluid level after 20 minutes and refill if necessary.

POWER CYLINDER SEAL

C-SERIES

Removal and Installation

The C-Series power cylinder cannot be disassembled. Only the oil seal and snap ring can be replaced.

1. Carefully clamp the power cylinder in a vise in a manner to prevent distortion, and remove the snap ring from the end of the cylinder.
2. Remove as much fluid from the cylinder as possible by stroking the piston rod in and out. Apply air pressure to the retracting port on the cylinder to blow out the seal.
3. After lubricating a new seal with automatic transmission fluid, position it on the piston. Install the seal with a suitable deep socket.
4. Install the retaining snap ring with the sharp edge facing out.

VALVE OR CYLINDER TUBE SEAT

Removal and Installation

If any of the control valve connector seats need replacement, use the following procedures:

1. Tap the existing hole in the tube seat. Use a 3/8 inch starting tap for the large tube seat and a 1/4 inch starting tap for the small seats. **Be sure to remove all metal chips from the tube seat port after tapping.**
2. Place a nut and large flat washer on a bolt of the same size as the tapped hole. The washer must be large enough to cover the tube seat port.
3. Thread the bolt into the tapped hole, and turn the nut to remove the tube seat.
4. Place a new tube seat in the port, and thread a bolt of the same size as the port into the port. Tighten the bolt enough to bottom the seat in the port.

DISASSEMBLY AND ASSEMBLY

The procedures given in Parts 13-33 and 34 under Major Repair Operation also apply to vehicles equipped with power steering.

POWER CYLINDER

ECONOLINE

Disassembly

1. Clamp the power cylinder in a vise, and remove the snap ring from the end of the cylinder (Fig. 5). **Be careful not to distort or crack the cylinder in the vise.**
2. Pull the piston rod out all the way to remove the scraper, bushing, and seals. If the seals cannot be removed in this manner, remove them from the cylinder with a sharp pick. **Take care, when using a pick, not to damage the shaft or seal seat.**

Assembly

When replacing the power cylinder seals, install all of the parts supplied in the repair kit for the cylinder being repaired.

1. Coat the new seals with Lubricant COAZ-19553-A to place the parts shown on the sketch on the piston rod which has been coated with the same grease.
2. Push the rod in all the way and install the parts in the cylinder with a deep socket slightly smaller than the cylinder opening

CONTROL VALVE

C-SERIES

Disassembly

1. Remove the four housing bolts and the drag link assembly (Fig. 7).
2. After unthreading the ball stud plug, remove the outer seat and spacer, the ball stud, and the inner seat, spring, and spring seat.
3. After removing and discarding the nut from the spool bolt, remove the spacer washer, the centering spring seats, the spring, the sleeve, the bushing seal plate, and the shim. **Notice that the spacer washer and the shim are not identical and note their relative positions.**
4. **Separate the valve housing from the outer sleeve, and remove the plate bushing.**
5. Remove the spool bolt and the inner sleeve from the outer sleeve.
6. Press on the spool to free the seals from the housing, and remove the seal and the spool. **Remove the spool very carefully to avoid nicks or scratches.**
7. If necessary to replace the check valve or its O-ring, remove the plug by means of a piece of appropriately bent brass rod inserted through the return port.

Assembly

1. After lubricating the spool seals and the spool with automatic transmission fluid, very carefully position the spool in the valve body. **The grooved valley between the lands must be toward the drag link.**
2. Position the seals. The inner lip of each seal should be toward the valve body.
3. Coat the outer diameter of the inner sleeve with C1AZ-19590-B lubricant and position the spool bolt and the inner sleeve in the outer sleeve. The inner sleeve should slide freely in the outer sleeve.
4. Position the plate bushing in the outer sleeve (Fig. 7), and position the valve body next to the outer sleeve. **Note that the valve body face has a shoulder that mates with the outer sleeve face.**
5. Position the shim (ground surface toward the spool), bushing seal plate, the sleeve, the spring, the spring seats, and the spacer washer on the spool bolt (Fig. 7). Install a new nut, and torque it to specification, then back it off one-sixth of a turn.
6. Position the drag link assembly against the valve body and install the housing bolts.
7. If installing on a vehicle, position the ball stud protruding from the pitman arm into the inner sleeve.
8. Tighten the ball stud plug until the spring is fully compressed. Then, back off the plug to the nearest point where the cotter pin can be inserted.

ECONOLINE

Disassembly

1. Disconnect the 4 fluid line fittings at the control valve, and drain the fluid from the lines.
2. Loosen the clamping nut and bolt at the end of the sleeve (Fig. 8).
3. Remove the roll pin from the control valve and link assembly.
4. Unthread the control valve from the link.
5. Wipe all fluid and loose dirt from the outside of the control valve.
6. Remove the centering spring cap, from the valve housing (Fig. 9). **When holding the control valve for disassembly, use a soft-jawed vise, and clamp the valve only around the sleeve flange to prevent damage to the housing, spool, or sleeve.**

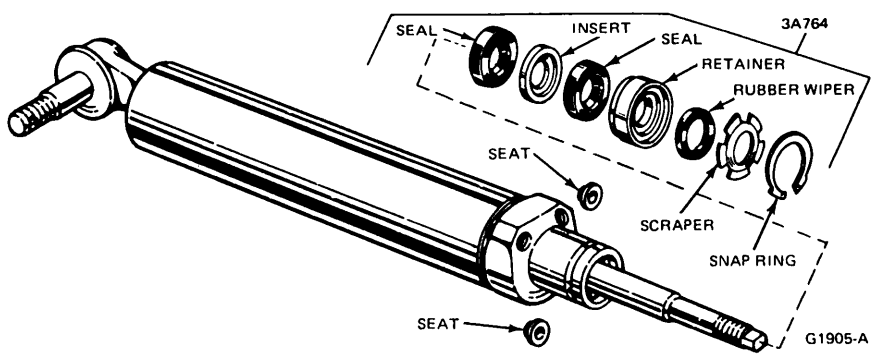

FIG. 5 Power Cylinder Econoline

7. Remove the nut from the end of the valve spool bolt. Remove the washers, spacer, centering spring, adapter, and bushing from the bolt and the valve housing.
8. Remove the two bolts that hold the valve housing and the sleeve together, and separate the housing from the sleeve.
9. Remove the plug from the valve sleeve.
10. Push the valve spool out of the centering spring end of the valve housing, and remove the seal from the spool.
11. Remove the spacer, bushing, and seal from the sleeve end of the valve housing.
12. Drive the stop pin out of the travel regulator stop with a punch. **Pull the head of the valve spool bolt tightly against the travel regulator stop before driving the pin out of the stop (Fig. 10).**
13. Turn the travel regulator stop counterclockwise in the valve sleeve to remove the stop from the sleeve.
14. Remove the valve spool bolt, spacer, and rubber washer from the travel regulator stop.
15. Remove the rubber boot and clamp from the valve sleeve.
16. Slide the bumper, spring, and ball stud seat out of the valve sleeve, and remove the ball stud socket from the sleeve.
17. After removing the return port hose seat, remove the return port relief valve.
18. After removing the plug and O-ring from both ends of the valve body, remove the reaction limiting valve springs, plunger and washers (Fig. 11).

Assembly

Before assembling the control valve, coat all parts except the seals with Automatic Transmission Fluid. Coat the seals with lubricant COAZ-19553-A.

1. Install the reaction limiting valve components, the spring and the components, the springs and the plugs.
2. Install the return port relief valve and the hose seat.
3. Insert one of the ball stud seats (flat end first) into the ball stud socket, and insert the ball stud into the sleeve window opening (Fig. 12).
4. Place the other ball stud seat, spring, and the spacer and bumper (Fig. 9) in the socket. Install and securely

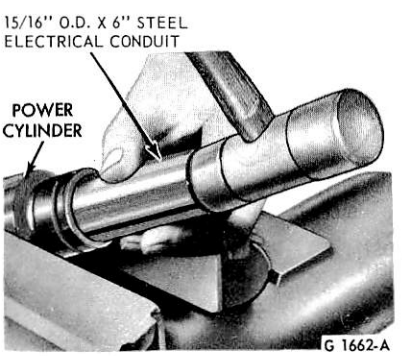

FIG. 6 Installing Power Cylinder Seals

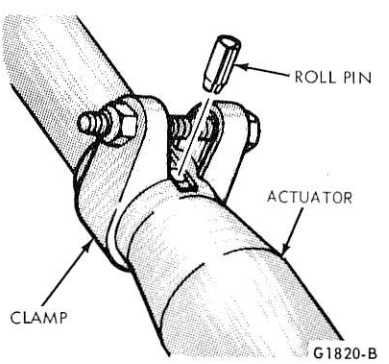

FIG. 8 Disconnecting Control Valve From Link

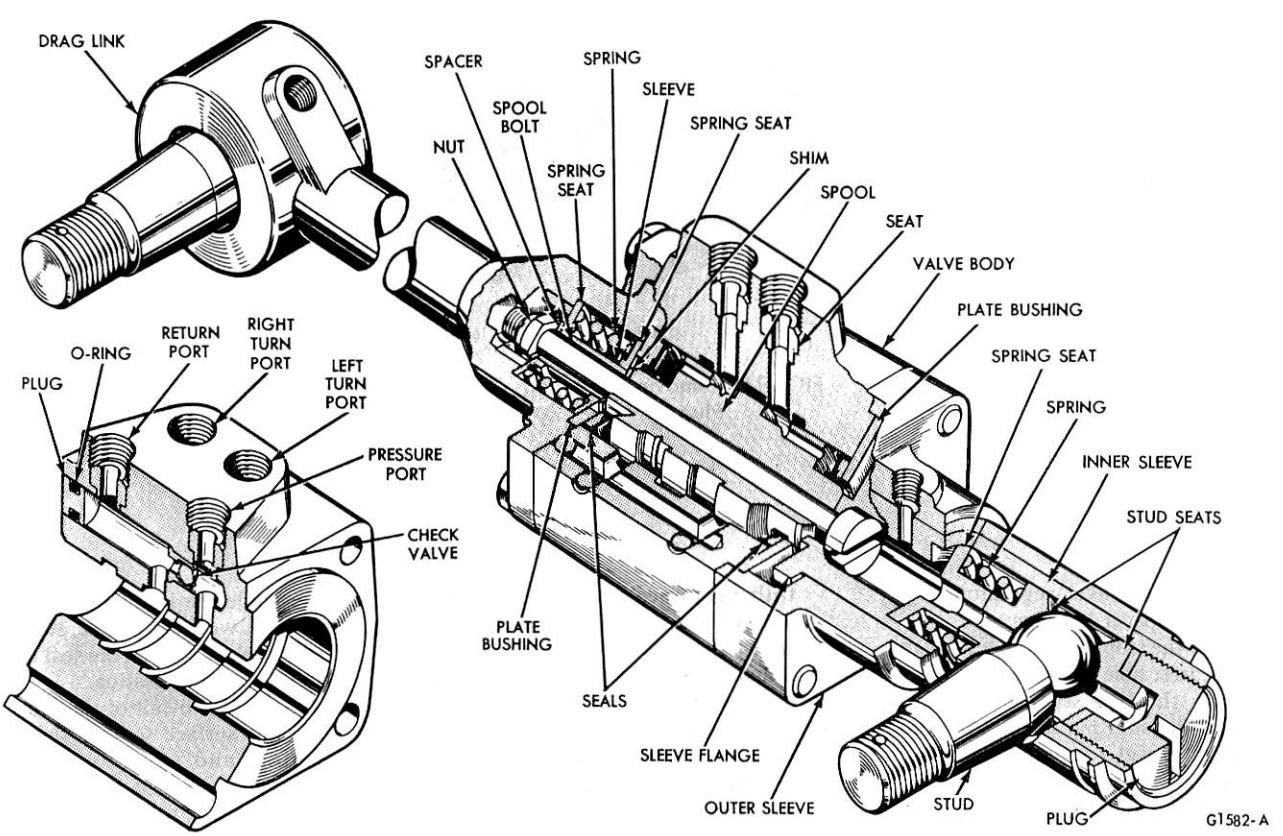

FIG. 7 Control Valve Typical

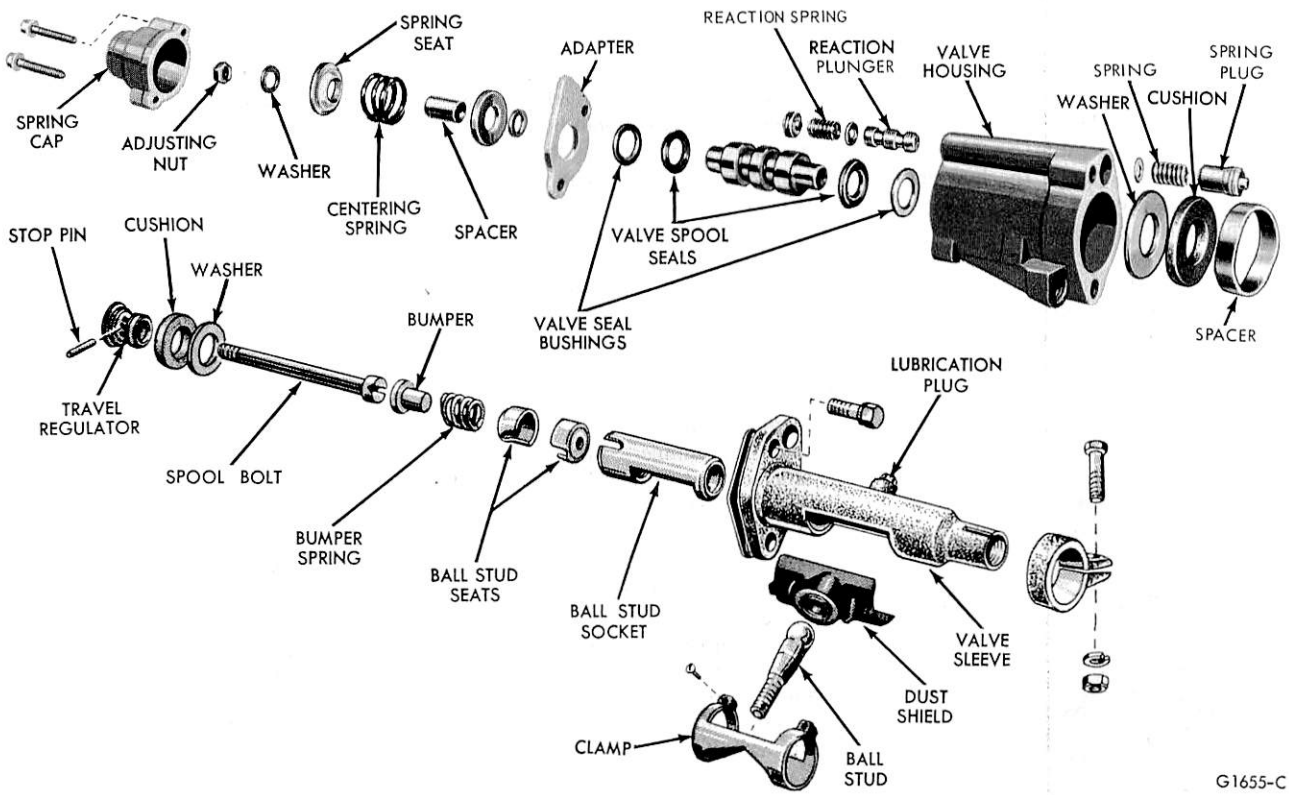

FIG. 9 Control Valve Disassembled

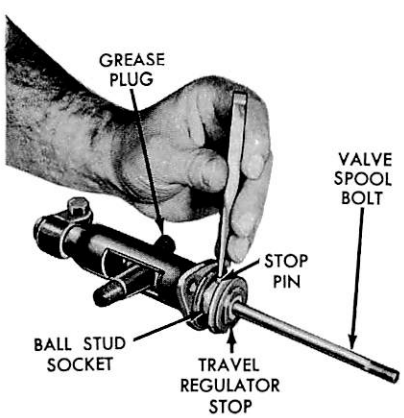

FIG. 10 Removing Stop Pin

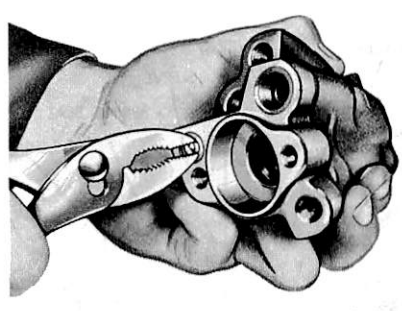

FIG. 11 Removing Reaction Valve Plug

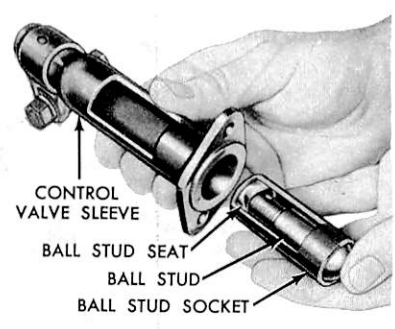

FIG. 12 Installing Ball Socket, Seal and Bracket

tighten the travel regulator stop until the spacer bottoms.

5. Loosen the stop just enough to align the nearest hole in the stop with the slot in the ball stud socket, and install the stop pin in the ball stud socket, travel regulator stop, and valve spool bolt (Fig. 10).
6. Install the rubber boot clamp and the plug on the control valve sleeve. **Make sure that the lubrication fitting is turned on tightly and does not bind on the ball stud socket.**
7. Insert the valve spool in the valve housing. **Rotate the spool while inserting it in the housing (Fig. 13).**
8. Move the spool toward the centering spring end of the housing and place the small seal bushing, and spacer in the sleeve end of the housing.
9. Press the valve spool against the inner lip of the seal and, at the same time, guide the lip of the seal over the spool with a small screwdriver **do not nick or scratch the seal or the spool during installation.**
10. Place the sleeve end of the housing on a flat surface so that the seal, bushing, and spacer are at the bottom end and push down the valve until it stops.
11. Carefully install the spool seal and bushing in the centering spring end

of the housing. Press the seal against the end of the spool, guiding the seal over the spool with a small screwdriver. **Do not nick or scratch the seal or the spool during installation.**

12. Pick up the housing and slide the spool back and forth in the housing to check for free movement.
13. Place the valve sleeve on the housing so that the ball stud is on the opposite side of the housing as the parts for the two power cylinder lines. Install the two bolts in the sleeve, and torque them to specification.
14. Place the adapter on the centering spring end of the housing and install the bushing, washers, spacers, and centering spring on the valve spool bolt.
15. Compress the centering spring, and install the nut on the bolt. Tighten the nut on the bolt. Tighten the nut snug until the spacer bottoms then loosen it not more than 1/4 turn (Fig. 14). The lock pin and ball stud free play can account for 1/4 turn. Make sure that the nut turns (90 degrees) on the threads of bolt. **Excessive tightening of the nut may break the stop pin at the travel regulator stop.**
16. Move the ball stud back and forth in the sleeve slot to check the spool for free movement. Apply COAZ-19553-a (silicone) grease at the sealing areas.
17. Lubricate the two cap attaching bolts. Install the centering spring cap on the valve housing, and torque the two cap bolts to specification.
18. Install the nut on the ball stud so that the valve can be positioned in a vise as shown in Figure 15. Then push forward on the cap end of the valve to check the valve spool for free movement.
19. Turn the valve around in the vise, and push forward on the sleeve end to check the spool for free movement.

PART 13-24 Steering Linkage-Manual

This Information Applies To All Models			
COMPONENT INDEX	Page	COMPONENT INDEX	Page
DRAG LINK Removal and Installation	24-02	SPINDLE CONNECTING ROD Removal and Installation	24-02
DRAG LINK AND TIE ROD END SEAL Removal and Installation	24-03	SPINDLE CONNECTING ROD END Removal and Installation	24-01
SPINDLE ARM Removal and Installation	24-03		

REMOVAL AND INSTALLATION

SPINDLE CONNECTING ROD END

ALL EXCEPT F-100-F-250 FOUR-WHEEL DRIVE AND BRONCO

Removal and Installation

A rod end should be replaced if the ball is excessively loose.

1. Remove the cotter pin and nut from the rod end ball stud (Figs. 1 and 2).
2. Remove the ball stud from the spindle arm.
3. Loosen the clamp bolt, and turn the rod end out of the rod.
4. After lubricating the threads of the new rod end, turn it into the rod about the same distance as the old rod end was installed. This will provide an approximate toe-in setting.
5. Install the ball stud in the spindle arm, tighten the nut to the specified torque, and install the cotter pin.
6. Check the toe-in. If necessary loosen the connecting rod end clamps, and adjust the toe-in. **Be sure to tighten the rod end clamps after adjusting the toe-in.** The clamps should be positioned 3/16 inch from the end of the rod, and with the clamp bolt at right angles to the slot in the rod if they are not fixed. The clamp bolt must be vertical, with the head up and the clamp facing forward (on WSeries trucks with the Center Point front axle, no part of the clamp or bolt should be in the 10 to 12 o'clock segment when viewed from the end).

F-100-F-250 FOUR-WHEEL DRIVE, BRONCO

Removal and Installation

1. Raise the vehicle on a hoist and disconnect the drag link from the spindle connecting rod end.

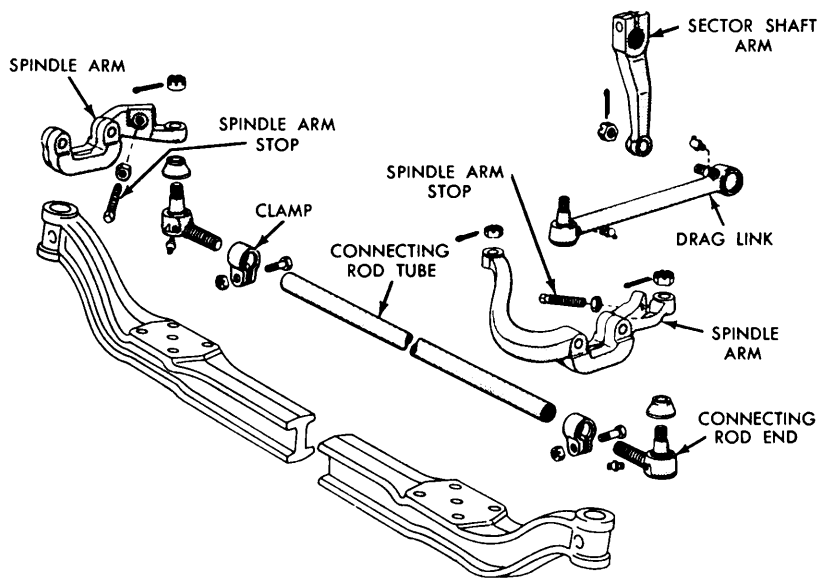

FIG. 1 Typical Steering Linkage with Bolt-On Spindle Arms

2. Disconnect the right spindle connecting rod end from the righ spindle arm.
3. Disconnect the left spindle connecting rod ends from the left spindle arm and remove the spindle connecting rod ends from the vehicle.
4. Position the connecting rod ends in a vise and loosen the connecting rod tube clamps (Fig. 3).
5. Remove the right (short) rod end from the connecting rod tube and remove the tube from the left (long) connecting rod end.
6. Clean and oil all threads on components that are to be re-used.
7. Install the connecting rod tube and clamps on the left spindle connecting rod end. Do not tighten the clamps.
8. Install the right connecting rod end in the tube and remove the assembly from the vise.
9. Position new dust seals (Fig. 3) on the left spindle connecting rod end and position the end to the left spindle arm.
10. Install the connecting rod end attaching nut and torque it to specification. Continue to tighten the nut until the slots on the nut are aligned with the hole in the ball stud and install the cotter pin.

11. Position new dust seals on the right spindle connecting rod end and position the end to the right spindle arm. Install the attaching nut and torque it to specification. Continue to tighten the nut until the nut castellations are aligned with the hole in the ball stud and install the cotter pin.
12. Position new seals (Fig. 3) on the drag link ball stud and position the drag link to the spindle connecting rod end. Install the attaching nut and torque it to specification. Continue to tighten the nut until the nut castellations are aligned with the hole in the ball stud and install the cotter pin.
13. Lubricate the spindle connecting rod ends and the drag link.
14. Check and correct the tire pressures to specification and lower the vehicle.
15. Check and adjust toe-in and tighten the connecting rod tube clamps to specification.

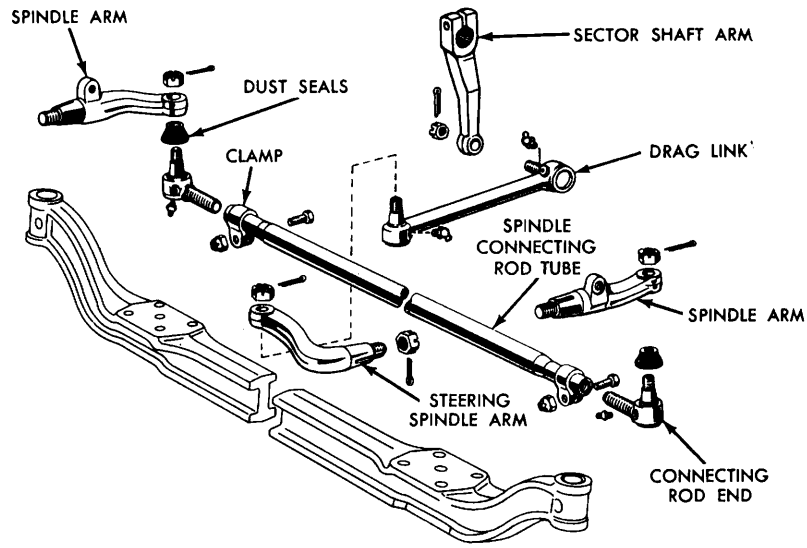

FIG. 2 Typical Steering Linkage with Tapered Spindle Arms

SPINDLE CONNECTING ROD

Removal and Installation

The spindle arm connecting rod should be replaced if the end threads are stripped and/or if it is damaged. **Do not attempt to straighten a bent rod.**

1. Loosen both connecting rod end clamps (Figs. 1 and 2).
2. Unthread the connecting rod until it drops off both ends. **One rod end has a right thread, the other has a left thread.**
3. Lubricate the threads on the connecting rod ends, place the clamps on the new connecting rod, and start the rod about one thread on one end.
4. Start the other end and continue to turn the rod until the rod ends have entered the rod about the same distance as the old rod was installed. This will provide an approximate toe-in setting.
5. Check the toe-in and adjust if necessary. **Be sure to tighten the connecting rod end clamps after adjusting the toe-in.** Position the clamps 3/16 inch from the end of the rod with the clamp bolt at right angles to the slot irod.

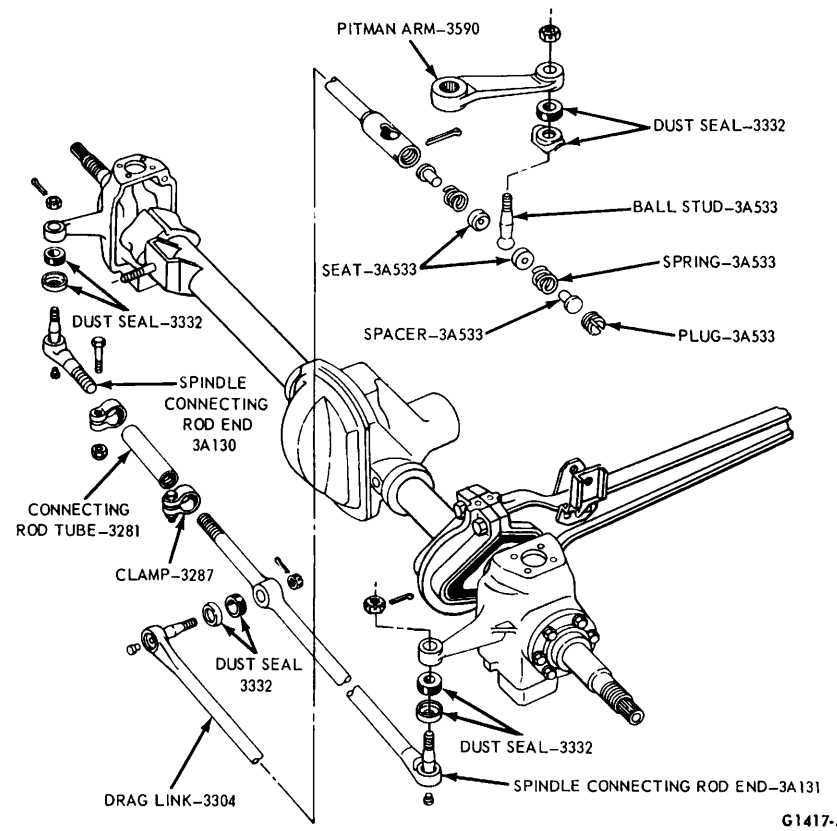

FIG. 3 Steering Linkage Disassembled—F-100

DRAG LINK

Removal and Installation

A drag link should be replaced if a ball stud is excessively loose and/or if the drag link is bent. **Do not attempt to straighten a drag link.**

Drag links on Models F-B-500-750 with manual or power steering and 5000 through 7000 pound front axles will have the word axle stamped on the end of the link adjacent to the ball stud socket. This end is to be attached to the axle steering arm (front of vehicle).

NON-ADJUSTABLE

1. Remove the cotter pins and nuts from the ball studs.
2. Remove the ball studs from the arms.

3. Position the drag link ball studs in the arms, and install the nuts. Torque the nuts to specification and install the cotter pins.

ADJUSTABLE

1. Remove the cotter pin and nut from the ball stud.
2. Remove the ball stud.
3. Remove the nut and bolt from the dust shield.
4. After removing the cotter pin and the threaded plug, remove the drag link.
5. Clean the ball seats and inspect them for wear.
6. Position the drag link ball stud, and install the nut. Torque the nut to specification and install the cotter pin.
7. Install the drag link on the sector arm ball, and assemble the socket.
8. Install the bolt and nut on the dust shield.
9. Check the ball stud for end play. If end play exists, the spring, seats or ball stud are probably damaged and should be replaced.

DRAG LINK AND TIE ROD END SEAL

F-,B-,LN-500-750 WITH 5000-7000 LB. AXLES, L-,LT-,LTS-,LN-,LNT-800 AND UP

Removal and Installation

1. Remove the old dust seal.
2. Wipe out all old grease from around the ball stud (do not use solvent).
3. Pack C1AZ-19590-B Lithium base grease liberally around the ballstud.
4. On units with the one piece dust seal, press the new dust seal into place using a deep socket or other suitable tool that will fit over the boot and press on the lower horizontal flange. On units with the keystone clamp, press the new seal into place on the socket body, slip the keystone clamp down to the shoulder of the seal and securely crimp into place.

SPINDLE ARM

Removal and Installation

A spindle arm should be replaced if it is bent and/or damaged in any way. **Do not attempt to straighten a bent spindle arm.**

BOLT-ON TYPE ARM

1. Remove the front wheel and brake drum.
2. Remove the cotter pin and nut from the connecting rod (and/or the drag link on the left side) ball stud, and remove the ball stud from the spindle arm.
3. Remove the cotter pin, lock washers, and nuts from the spindle arm attaching bolts (Fig. 1), and remove the spindle arm. It is not necessary to remove the spindle arm attaching bolts unless they are damaged and must be replaced.
4. Install the steering stop adjusting bolt, and lock nut in the spindle arm, if so equipped.
5. Position the spindle arm and lock washers on the attaching bolts, install and tighten the nuts to the specified torque, and install the cotter pin.
6. Install the connecting rod (and/or the drag link on the left side) ball stud in the spindle arm, tighten the nut to the specified torque, and install the cotter pin.
7. Install the front brake drum and wheel, and check the toe-in. **Be sure to tighten the connecting rod end clamps if the toe-in is adjusted.**
8. Adjust and lock the steering stop adjusting bolts.

TAPERED ARM TYPE

1. Remove the connecting rod end ball stud or the drag link ball stud from the spindle arm.
2. Remove the cotter pin and attaching nut from the spindle arm, and remove the spindle arm from the spindle. Drive out the spindle arm if necessary (Fig. 2).
3. Install spindle arm in the spindle. The spindle hole is slotted to position the spindle arm with a key.
4. Install the spindle arm attaching nut and tighten it to the specified torque. Install a new cotter pin through the nut and spindle arm.
5. Install the connecting rod end ball stud or the drag link ball stud in the spindle arm and install and tighten the ball stud nut to specified torque. Install a new cotter pin through the nut and ball stud.
6. Check the toe and adjust if necessary.
7. Adjust and lock the steering stop adjusting bolts.

PART 13-33 Manual Steering Gear—Recirculating Ball

DESCRIPTION

STEERING GEAR

Figs 1 and 2 show the recirculating ball type steering gear. The steering system combines the low friction parallelogram linkage and the conventional recirculating ball-nut steering gear. Friction is minimized by the ball-nut, which is mounted on the steering worm (or shaft), where all steering action is accomplished by free rolling ball bearings between the nut and worm. There is no direct contact between the steering worm and the ball-nut assembly.

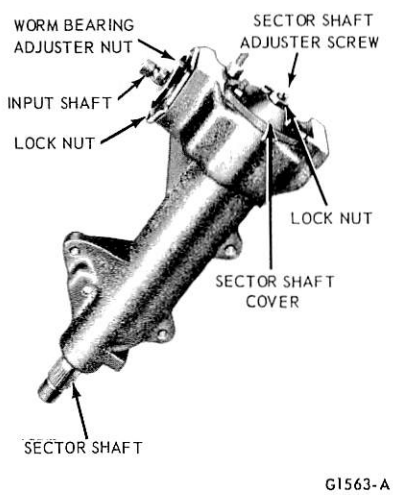

FIG. 1 Manual Steering Gear — Recirculating Ball — F-100 thru F-350 (4 x 2)

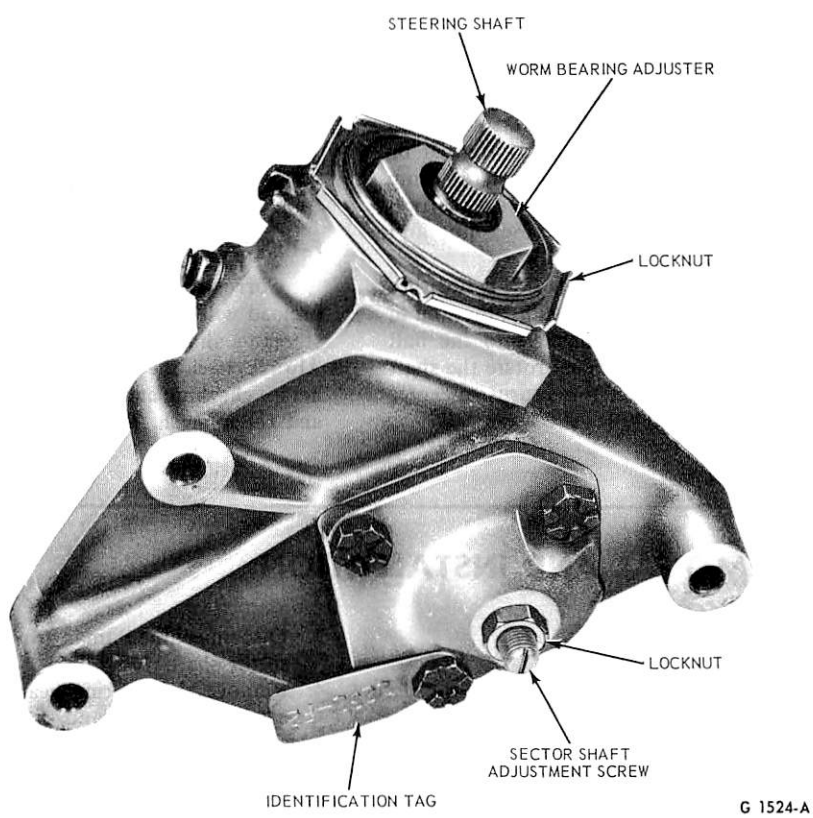

FIG. 2 Manual Steering Gear — Recirculating Ball — Econoline

ADJUSTMENTS

STEERING WORM AND SECTOR

ECONOLINE

The steering gear must be removed from the vehicle to properly make a preload and mesh load adjustment. Therefore it should be determined that the steering column is aligned properly and not causing excessive turning effort before attempting to adjust the gear.

The ball nut assembly and the sector gear must be adjusted properly to maintain minimum steering shaft end play (a factor of preload adjustment) and minimum backlash between sector gear and ball nut. There are only two possible adjustments within the recirculating ball-type steering gear, and **these should be made in the following order to avoid damage or gear failure.**

1. Loosen the nut which locks the sector shaft adjusting screw (Fig. 2) and turn the adjusting screw counterclockwise approximately three turns.
2. Measure the worm bearing preload by attaching an in-lb torque wrench to the input shaft (Fig. 3). Read the torque required to rotate the input shaft approximately 1 1/2 turns either side of center. If the torque or preload is not within specifications, adjust the steering gear as explained in the next step.
3. Loosen the input shaft bearing adjuster lock nut, and tighten or back off the bearing adjuster to bring the preload within the specified limits. Tighten the lock nut and recheck the preload.
4. Turn the input shaft slowly to either stop. **Turn gently against the stop to avoid possible damage to the ball return guides.** Then rotate the shaft approximately three turns to center the ball nut.

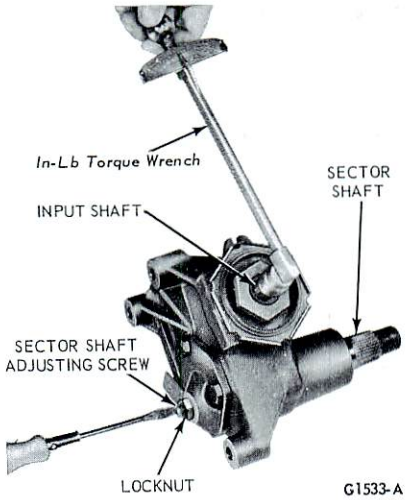

FIG. 3 Setting Mesh Load

5. Turn the sector adjusting screw clockwise until the specified pull is obtained to rotate the worm past its center (Fig. 3). With the steering gear position on center and the sector shaft retained to prevent rotation, check the lash between the ball nuts, balls and worm shaft by applying a 15 in-lb torque on the steering gear input shaft, in both right and left turn directions. Total travel of the wrench should not exceed 1 1/4 inches when applying a 15 in-lb torque on the steering shaft.
6. Tighten the sector adjusting screw lock nut, and recheck the backlash adjustment.

WORM BEARING PRELOAD

F-100-350 (4 X 2)

Correctly adjusted worm bearing preload will help to eliminate excessive steering shaft and worm end play. **Always check the worm bearing preload before checking and adjusting the worm and roller mesh. The worm and roller mesh should always be checked and adjusted after checking and adjusting the worm bearing preload.**

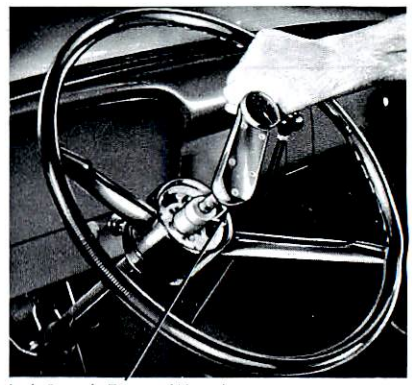

FIG. 4 Checking Steering Gear Preload

1. Remove the Pitman arm from the steering gear sector shaft.
2. Disconnect the horn wire at the horn relay. Remove the horn button and spring from the steering wheel.
3. Turn the steering wheel to the end of its travel.
4. Place an in-lb torque wrench on the steering wheel nut (Fig. 4). Measure the lowest torque required to turn the wheel at a constant speed. The lowest torque reading is the worm bearing preload. If the torque (preload) is not within specification (at the end of this Part), adjust as described in step 5.
5. Loosen the steering shaft bearing adjuster lock nut and tighten or loosen the bearing adjuster (Fig. 1) to bring the preload to specifications. Tighten the steering shaft bearing adjuster lock nut and recheck the preload.

REMOVAL AND INSTALLATION

STEERING GEAR

F-100 THRU F-350 (4 X 2)

Removal

1. Remove the bolt that attaches the flex joint to the steering gear (Fig. 5). Remove the brake line bracket.
2. Raise the front of the vehicle and install safety stands.
3. Disconnect the Pitman arm from the sector shaft.
4. Remove the steering gear housing attaching bolts, and remove the steering gear.

Installation

1. With the steering wheel spokes aligned and the sector shaft in the center position, install the steering gear. Torque all attaching bolts to specification. Reinstall the brake line bracket to the steering gear cover studs.
2. With the wheels straight ahead, connect the Pitman arm to the sector shaft.
3. Remove the steering gear filler plug and housing lower cover bolt. After turning the steering wheel to the left

to move the ball nut away from the filler hole, fill the steering gear with the correct lubricant. Fill the gear until lubricant comes out of the housing cover lower bolt hole. Install the filler plug and the cover bolt. Torque the bolt to specification.

ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Remove the attaching bolt from the lower half of the flex coupling (Fig. 6).
3. Disconnect the Pitman arm from the drag link with Tool 3290-C.
4. While supporting the steering gear, remove the three gear-to-side rail attaching bolts and flat washers. Lower the gear.
5. Remove the Pitman arm attaching nut. Remove the Pitman arm with Tool T64P-3590-F.

Installation

1. Center the input shaft (approximately three turns from either stop).
2. Place the Pitman arm on the sector shaft making sure that it is pointing downward. Install and torque the attaching nut to specification.
3. Fill the steering gear to the proper level with the specified lubricant.
4. Raise the steering gear into position making sure that the splines on the input shaft engage the flexible coupling. Install and torque the three special (grade 8) mounting bolts and special washers (hardened) to specification.
5. Connect the drag link to the Pitman arm and torque the nut to specification. Install a new cotter pin.
6. Install the flexible coupling attaching bolt and torque it to specification.

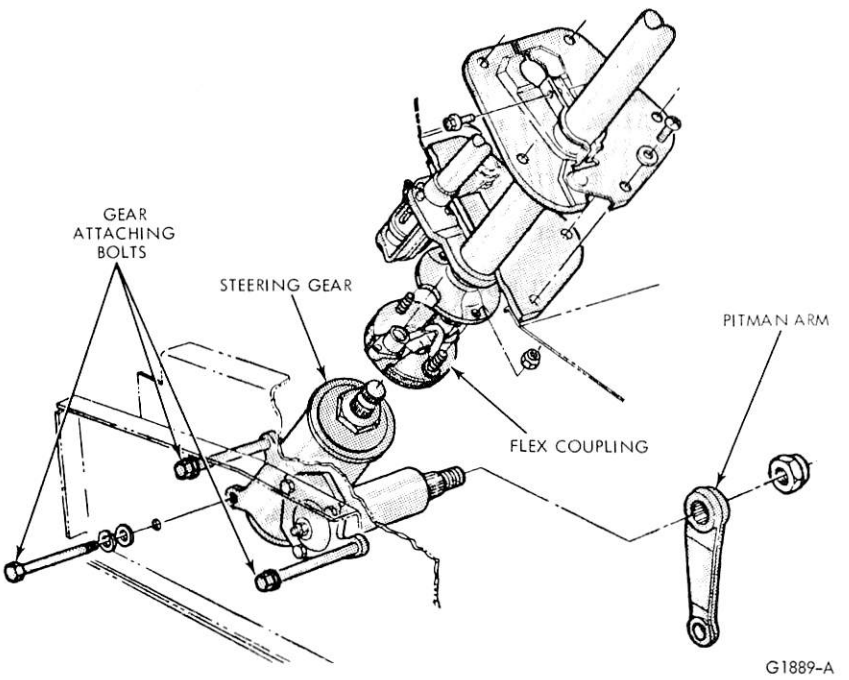

FIG. 6 Steering Gear Installation — Econoline

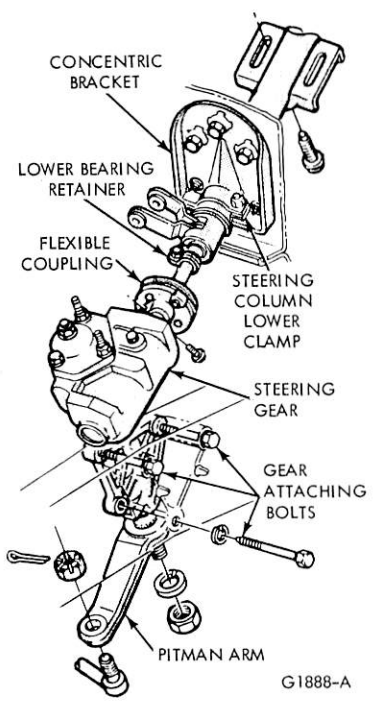

FIG. 5 Steering Gear Installation — F-100, 250 and 350

STEERING WHEEL

Removal and Installation

1. Disconnect the horn wire at the bullet connector below the instrument panel.
2. Remove the horn button or ring by pressing down and turning it counterclockwise.
3. Remove the steering wheel nut. Install a steering wheel puller (Fig. 7), and remove the steering wheel.
4. Make sure the steering column upper bearing sleeve and spring are in position at the top of the steering shaft if so equipped. Position the steering wheel and press it onto the shaft. On F-Series, with the wheels straight ahead, position the steering wheel on the steering shaft with the clear vision opening at the top. This will point the lower spoke straight down.
5. Install a new steering wheel attaching nut and torque to specification.
6. Stake the steering shaft at one point with a center punch to prevent the nut from coming off.
7. Install the horn button and connect the horn wire.

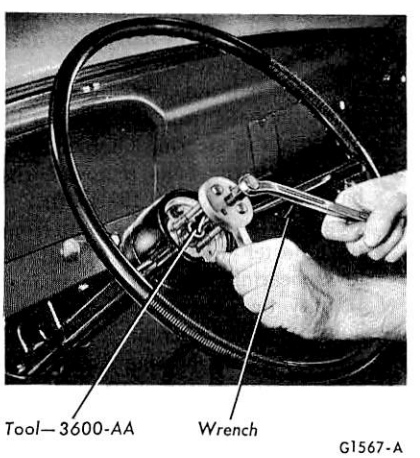

FIG. 7 Removing Steering Wheel — Typical

DISASSEMBLY AND ASSEMBLY

STEERING GEAR

Disassembly

1. Rotate the steering shaft to the center position and remove the steering shaft bearing adjuster lock nut (Figs. 8 and 9).
2. Loosen the worm bearing adjuster nut and remove the adjuster assembly and the steering shaft upper bearing.
3. Remove the sector shaft adjuster screw lock nut and loosen the adjuster screw about one turn (Figs. 9 and 10).
4. Remove the sector shaft cover attaching screws and studs and remove the cover by turning the adjuster screw clockwise. **Keep the shim with the adjuster screw.**
5. Remove the sector shaft from the housing.
6. Carefully pull the steering shaft and ball nut from the housing and remove the steering shaft lower bearing. **To avoid possible damage to the ball return guides, keep the ball nut from running down to either end of the worm. Disassemble the ball nut only if there is indication of binding or tightness.**
7. Remove the ball nut guide retainer and guides from the ball nut. **Keep the guide side of the ball nut up until ready to remove the balls.**
8. Turn the ball nut over, and remove all of the balls from the ball nut by rotating the steering shaft side to side. With the balls removed, the ball nut will slide off the shaft.
9. Remove the upper bearing cup from the adjuster (Figs. 8 and 9) and the lower bearing cup from the housing. It may be necessary to tap the housing or adjuster on a block of wood to jar the bearing cups loose.
10. Remove the sector shaft seal and lower bearing from the housing with Tool T62F-3576-A (Fig. 11). Then, with the same tool, remove the upper bearing on F-100, 250 and 350 (4 x 2) vehicles. **Remove the sector shaft bearings only if preliminary inspection shows damage.**
11. Clean and inspect the housing and all parts.

Assembly

1. If the sector shaft bearings have been removed, install the sector shaft lower bearing in the housing with Tools T62F-3576-A and T64K-3576-B as shown in Figs. 12, 13 and 14. Then, install a new seal in the same way.
2. On F-100, 250 and 350 (4 x 2) vehicles turn the gear housing over and install the upper bearing with the same tools. Apply enough C3AZ-19578-A lubricant to fill the pocket in the housing between the sector shaft bearings.
3. Install the steering shaft upper bearing cup in the adjuster and the lower bearing cup in the housing (Figs. 8 and 9). If the seal in the bearing adjuster was removed, install a new seal. Swab the inside diameter of the ball nut and the outside diameter of the worm and gear with lubricant C3AZ-19578-A prior to assembly.
4. Insert the ball guides (Figs. 8 and 9) into the holes of the ball nut, tapping them lightly with the wood handle of a screwdriver if necessary to seat them.
5. Insert one half of the balls into the hole in the top of each ball guide. It may be necessary to rotate the shaft slightly one way, then in the opposite direction to distribute the balls in the circuit.
6. After the balls are installed, install the ball guide clamp. Torque the screws to specification. Check the worm shaft to make sure that it rotates freely.
7. Coat the threads of the steering shaft bearing adjuster, the housing cover bolts, and the sector adjusting screw with a suitable oil-resistant sealing compound. **Do not apply sealer to female threads, and especially avoid getting any sealer on the steering shaft bearings.**
8. Coat the worm bearings, sector shaft bearings and gear teeth with gear lubricant.
9. Clamp the housing in a vise, with the sector shaft axis horizontal, and position the steering shaft lower bearing in its cup.
10. Position the steering shaft and ball nut assemblies in the housing.
11. Position the steering shaft upper bearing on the top of the worm and install the steering shaft bearing cup adjuster. Install the adjuster lock nut with the flat side against the bearing adjuster. Leave the nut loose.
12. Adjust the worm bearing preload (Figs. 15 and 16) using an in-lb torque wrench. See the Specification Section at the end of this Part for the specified preload. New steering gear assemblies are factory-adjusted to specification.
13. Position the sector adjusting screw and adjuster shim, and check the end clearance which should not exceed 0.002 inch between the screw head and the end of the sector shaft. If clearance is greater than 0.002 inch, add enough shims to reduce the end play to within the 0.002 inch tolerance.
14. Start the sector shaft pilot into the housing cover and then, using a screwdriver through the hole in the cover, turn the adjusting screw counterclockwise to pull the pilot into the cover.
15. Install a new gasket on the housing cover.
16. Rotate the steering shaft until the ball nut teeth are in position to mesh with the sector gear, tilting the housing so that the ball nut will tip toward the housing cover opening.
17. Lubricate the sector shaft journal and install the sector shaft and cover.
18. With the housing cover turned out of the way, fill the gear with the specified amount of gear lubricant. Push the housing cover and sector shaft assemblies into place, and install the top housing cover bolts. **Do not tighten the cover bolts until it is certain that there is some lash between ball nut and sector gear teeth. While holding or pushing the cover away from the ball nut, torque the bolts to specification.**
19. After loosely installing the sector shaft adjusting screw lock nut, adjust the sector shaft mesh (backlash) as shown in Fig. 17. See Specifications section for the specified mesh load.

DESCRIPTION

STEERING GEAR

F-100-250 (4 X 4) AND BRONCO

The steering gear is a worm and roller type gear. It is attached to the frame side rail forward of the front axle and steering linkage.

The worm, which is part of the input shaft rotates on ball bearings and preload is obtained by shim gaskets between the end plate and the housing (Fig. 1). The sector shaft and roller, which is combined as an integral unit, rotates in bushings in the lower part of the housing. Worm and roller adjustment is controlled by an adjusting screw in the top end of the sector shaft. This screw is threaded into the housing cover and is used to adjust the mesh of the worm and roller by pushing the sector shaft roller against the worm.

All Models—500 Thru 9000, F-250 (4 X 4) and P-Series

The worm and roller type steering gear assemblies (manual steering) used on all models are similar in design but differ in size and method of attachment to the frame. A cutaway view of a typical steering gear is shown in Fig. 2.

The steering linkage consists of the steering sector shaft (Pitman arm), the drag link, idler arm (C-Series with power steering only), the spindle connecting rod, and the spindle arms.

ADJUSTMENTS

WORM BEARING PRELOAD

F-100 4-Wheel Drive

1. Disconnect the Pitman arm from the sector shaft with T64P-3590-F.
2. Disconnect the wire socket at the horn relay. Remove the horn button and spring.
3. Turn the steering wheel to the end of its travel in either direction.
4. Place an in-lb torque wrench on the steering wheel attaching nut, and measure the torque required to keep the wheel moving at a constant rate for approximately 1/4 to 1/2 turn. If the torque, or preload is not within specifications, remove or add gasket shims between the worm shaft bearing retainer cover and the steering gear housing (Fig. 1) to adjust the worm bearing preload to specification. Install the cover and torque the attaching bolts to specification. Then, recheck the worm preload to be sure it has not changed after the cover bolts have been tightened. **If erratic readings are experienced, disconnect the steering shaft joint at the steering gear. Then, check the torque required to rotate the steering shaft. If the torque is measurable, add it to the worm bearing preload specification.**
5. After adjusting the worm preload, turn the gear to the other end of its travel and recheck the preload.
6. Check the steering gear lubricant level and add lubricant as necessary (Part 13-01).

Bronco

1. Remove the steering gear as described in Removal and Installation.
2. Loosen the mesh and roller adjusting lock nut. Back off adjusting screw 2-3 turns.
3. Place an in-lb torque wrench on the input shaft. Check the torque required to rotate the input shaft 1 1/2 turns either side of center. If the torque or preload is not within specifications, remove or add gasket shims between the worm shaft bearing retainer cover and the steering gear housing (Fig. 1) to

adjust the worm bearing preload to specification.
4. Tighten the mesh and roller adjusting screw 2-3 turns and perform the worm and roller mesh adjustment.
5. Install the steering gear as described in Removal and Installation.
6. Check the steering gear lubricant level and add lubricant as necessary (Part 13-01).

F-B-L-W-C-500-9000

1. Remove the steering gear from the vehicle.
2. Place a 12 point, 13/16 inch socket on the lower steering shaft serrations. Attach an in-lb torque wrench to the socket and turn the steering gear at a constant speed. The lowest torque reading is the worm bearing preload. If the torque is not within specification (at the end of this Part), make the adjustment as outlined in step 3.
3. To adjust the worm bearing preload, remove or add gasket shims between the worm shaft bearing retainer (Fig. 2) to bring the worm bearing preload to the proper specifications. install the cover and torque to specifications.
4. Adjust the worm and roller mesh preload.
5. Install the steering gear in the vehicle.

WORM AND ROLLER MESH

The worm bearing preload should always be checked and adjusted, if necessary, before the worm and roller mesh is checked and adjusted.

1. Remove the steering gear from the vehicle.
2. Place an in-lb torque wrench on the steering gear input shaft. Measure the torque required to turn the steering wheel through the straight ahead (high point) position. The highest torque reading is the worm and roller mesh preload. If the preload is not within specification (at the end of this Part), adjust as outlined in steps 3 through 5.
3. To adjust the mesh, loosen the adjusting screw lock nut on the side of the steering gear housing (Fig. 3), and adjust the worm and roller mesh, or by turning it outward (counterclockwise) to loosen the mesh.
4. After adjusting the mesh, hold the adjusting screw stationary with a screwdriver and tighten the lock nut.
5. Recheck the mesh adjustment. If the mesh is still not correct, repeat the adjustment procedure.
6. Install the steering gear and fill it to the correct level with the specified lubricant.

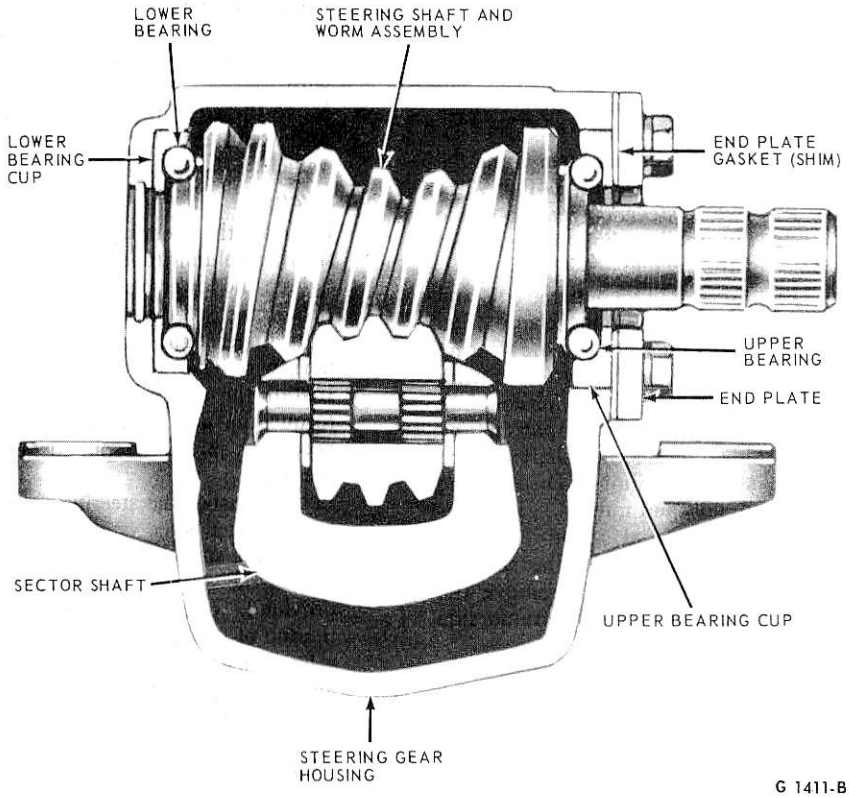

FIG. 1 Steering Gear — F-100-250 (4 x 4) and Bronco

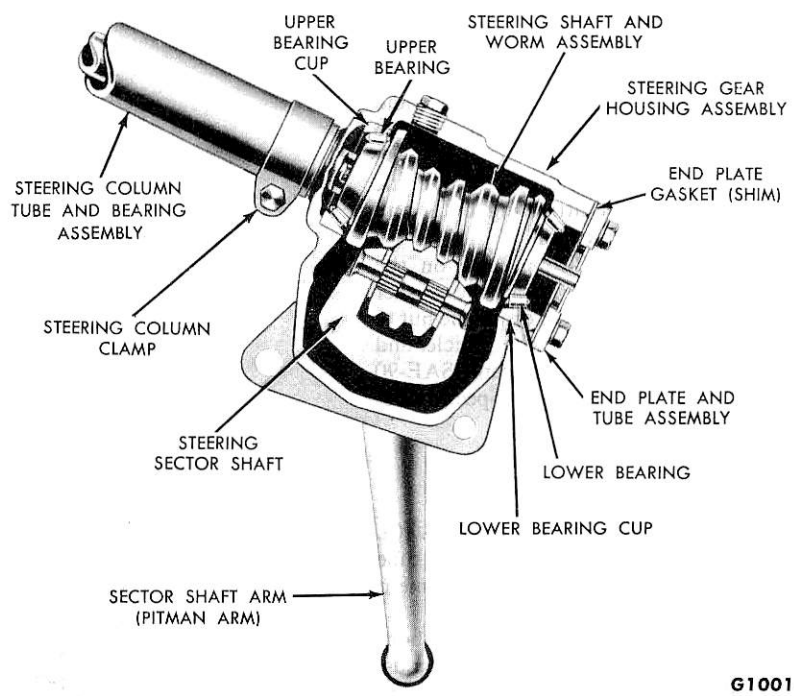

FIG. 2 Typical Manual Steering Gear — Sectional View

REMOVAL AND INSTALLATION

STEERING GEAR

BRONCO, F-100-250 (4 X 4)

Removal

1. Raise the vehicle on a hoist and remove the Pitman arm attaching nut and lock washer.
2. Remove the Pitman arm from the sector shaft with Tool T64P-3590-F.
3. Remove 3 steering gear-to-frame side rail attaching bolts and nuts and lower the vehicle.
4. Remove the flex coupling bolt and nut from the coupling clamp (Fig. 4). Loosen the clamp on the steering shaft at the end of the steering column and separate the coupling from the steering gear input shaft by pushing the steering shaft toward the steering column. Discard the clamp, bolt and nut.
5. Remove and discard the flex coupling clamp from the steering gear input shaft, and remove the steering gear from the frame side rail.

Installation

1. Position the steering gear to the frame side rail and install the attaching bolts and nuts.
2. Position the steering shaft flex coupling and a new clamp to the steering gear input shaft and install the clamp bolt and nut (Fig. 4). Torque the bolt and nut to specification.
3. Position a new steering shaft clamp at the end of the steering column and tighten the bolt and nut to specification.
4. Raise the vehicle and torque the steering gear attaching bolts and nuts to specification.
5. Position the Pitman arm on the sector shaft and install the washer and attaching nut. Torque the nut to specification, lower the vehicle, and fill the gear with lubricant (SAE-90 EP Engine Oil, Ford Spec.M-568-C).

P-SERIES

Removal

1. Remove the steering wheel (Fig. 10).
2. Remove the steering column tube bracket bolts from the instrument panel.
3. Raise the front of the vehicle about 10 inches, and install safety stands.
4. Remove the sector shaft arm from the sector shaft, and remove the steering gear attaching bolts (Fig. 5). If necessary, spread the sector shaft opening in the arm.
5. Loosen the steering column lower clamp, and disconnect the horn wire.
6. Move the steering gear to the left, and remove it from beneath the vehicle.

Installation

1. Position the steering gear in the steering column tube, and partially tighten the lower clamp.
2. Install the steering gear attaching bolts finger tight, and connect the horn wire.
3. Install the sector shaft arm and torque the nut to specification. If necessary, spread the split portion of the arm.
4. Loosely install the steering column tube bracket bolts.
5. Install the steering wheel.
6. Adjust the steering column tube to provide 1/16 inch clearance between the top of the tube and the steering wheel hub, and tighten the instrument panel bolts.
7. Tighten the low clamp bolt, and torque the steering gear attaching bolts to specification.
8. Lower the vehicle.

F-B-500-750, 6000-7000

Removal

1. Loosen the steering column lower clamp and slide the clamp down (Fig. 6).
2. Remove the bolt and nut retaining the Pitman arm from the sector shaft using Tool T64P-3590-F.
3. Remove the nuts, bolts, cotter pin and the strap retainer on all models except those equipped with 9000 lb axles, that hold the steering gear housing on the frame side member.
4. Remove the steering gear assembly from under the vehicle.

Installation

1. Install the steering gear assembly from underneath the vehicle and tighten the mounting bolts and nuts (and strap retainer if so equipped) finger tight.
2. Connect the steering column lower clamp and torque to specification.
3. Torque the two upper steering gear housing-to-frame mounting nuts to specification.
4. Install the bottom nut and cotter pin and torque to specification (50-70 ft-lb).
5. Install the Pitman arm on the sector shaft and torque the retaining nut to specification.

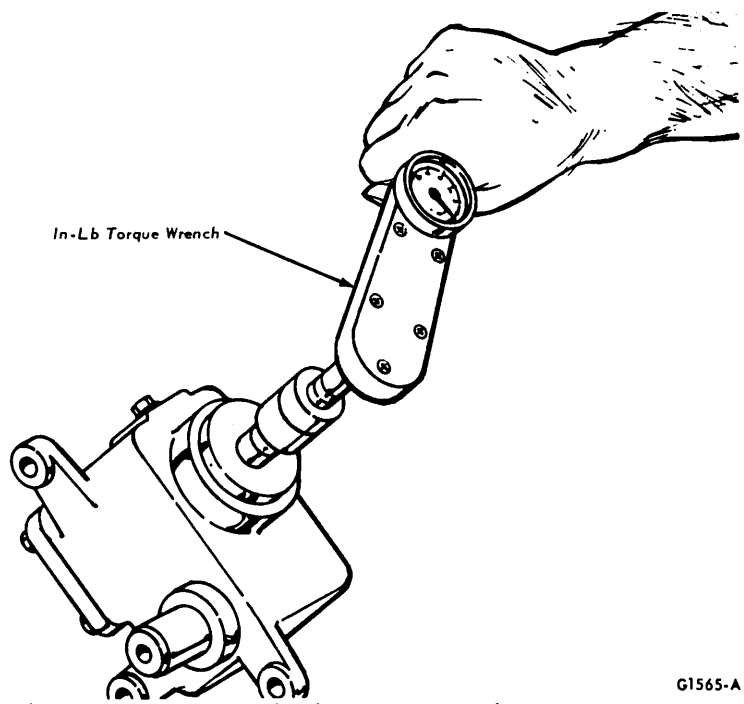

FIG. 3 Checking Steering Gear Preload — F-B-L-W-and C-500-9000

L-N-500-900, 6000-9000, L-LT-LNT-W-WT-800-900, 8000-9000

Removal

1. Remove the bolt, nut and cotter pin retaining the Pitman arm to the sector shaft and remove the Pitman arm from the sector shaft using Tool T64P-3590-F.
2. Remove the bolt and nut retaining the U-joint to the steering gear input shaft and slide the joint up off the input shaft (Figs. 7 and 8).
3. Remove the bolts, nuts, cotter pins and strap retainers (if so equipped) retaining the steering gear or the steering gear bracket to the frame side rail and remove the steering gear.

Installation

1. Position the gear (or gear and bracket) to the side rail. Install the bolts, nuts and strap retainers if so equipped and torque to specification. Install the cotter pins (advance to next castellation if necessary after torquing to specification).
2. With the wheels and steering wheel in the straight ahead position place the steering shaft U-joint on the steering gear input shaft. Install a new bolt and nut to retain. **Make certain the bolt is engaged in the slot of the steering gear input shaft. Torque to specification.**
3. Position the Pitman arm to the steering gear sector shaft and install the bolt and nut. On W and L-Series trucks, the slash marks on the Pitman arm and the sector shaft should be aligned when full serrations are evident. Torque to specification and install the cotter pin (advance to next castellation if necessary).

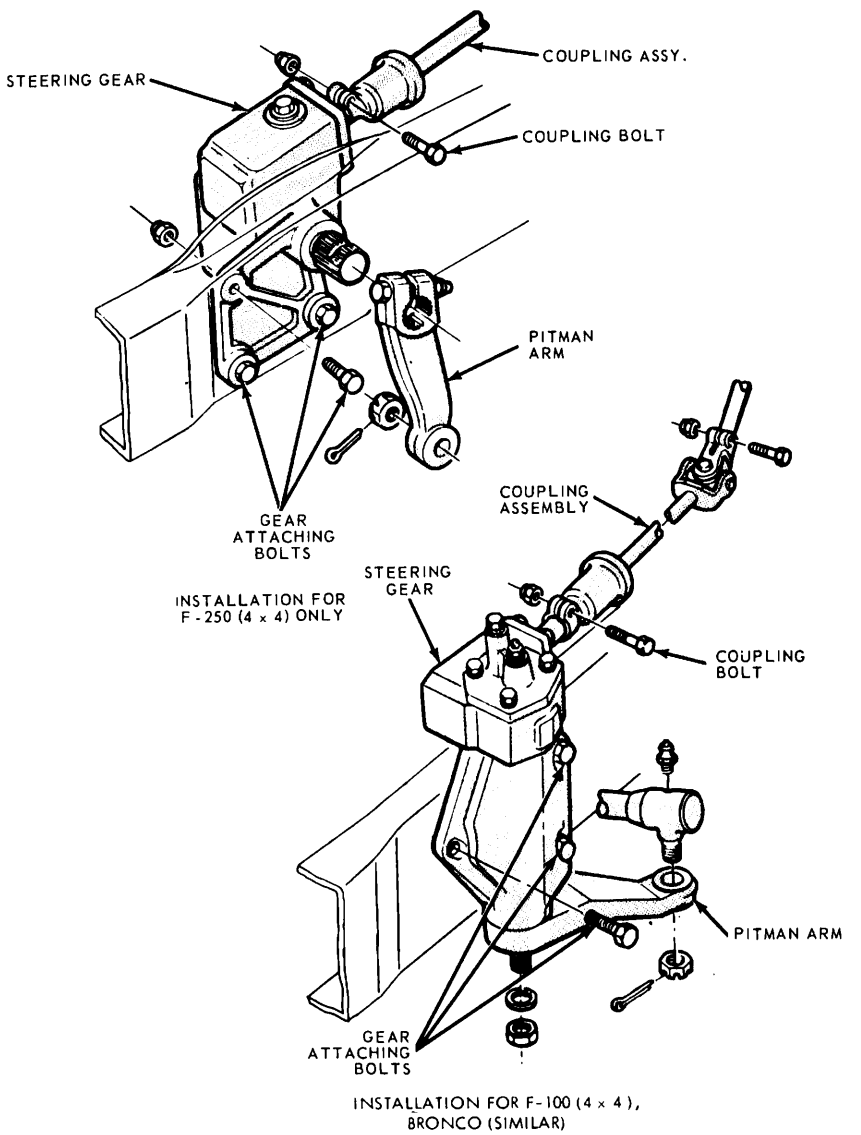

FIG. 4 Steering Gear Installation — Bronco, F-100, F-250 (4 x 4)

C-SERIES

Removal

Tilt the cab up.

1. Remove the horn wire brush from the steering column just below the instrument panel bracket.
2. Remove the universal joint-to-steering gear attaching bolt (Fig. 9).
3. Turn the wheels to the right, remove the sector arm (Pitman arm) attaching nut and bolt, and pry the sector arm off the sector shaft. If necessary, spread the sector shaft opening in the arm.
4. Remove the steering gear housing attaching bolts, and remove the steering gear.

Installation

1. Position the steering gear housing on the frame side rail, install the housing attaching bolts, torque the nuts to specifications, and install the cotter pins to lock the nuts.
2. Center the steering gear input shaft. Turn the steering wheel as required to position the lower spoke in a vertical position.
3. Have a helper push the steering shaft down until the universal joint is in position on the steering gear input shaft. Install and tighten the universal joint attaching bolt and lock nut.
4. Install the sector arm (Pitman arm) on the sector shaft, making sure the lock bolt slot in the sector shaft lines up, and install the bolt and nut. Torque the nut to specifications. If necessary, spread the sector shaft opening in the arm.
5. Connect the horn wire, and test the horn operation.
6. Road test the vehicle for proper steering operation.

STEERING WHEEL

Removal and Installation

1. Disconnect the horn wire at the bullet connector below the instrument panel. On a C-Series vehicle, disconnect the horn wire at the bullet connector under the instrument panel just beyond the horn brush.
2. Remove the horn button or ring by pressing down and turning it counterclockwise.

3. On all C-N-F-W Series trucks (except F-B Medium), remove the set screw located in one of the wheel pulling holes. Remove the steering wheel nut. Install a steering wheel puller (Fig. 10), and remove the steering wheel.
4. Make sure the steering column upper bearing sleeve and spring are in position at the top of the steering shaft if so equipped. Position the steering wheel and press it onto the shaft. On F-and P-Series with the wheels straight ahead, position the steering wheel on the steering shaft with the clear vision opening at the top. This will point the lower spoke straight down. On B-Series, install the steering wheel with the clear vision opening at the bottom and the single spoke pointing straight up.
5. Install a new steering wheel attaching nut and torque to specification.
6. On all C-N-F-W Series trucks (except F-B Medium), install the set screw in one of the wheel pulling holes. Select the hole with the minimum clearance to the nut which should be advanced to allow space along the flat.
7. Install the horn button and connect the horn wire.

DISASSEMBLY AND ASSEMBLY

Fig. 11 shows the special tool applications for steering gears covered in this section. The gears can be identified by the output shaft diameter.

STEERING GEAR

F-100-250 (4 X 4), BRONCO AND P-SERIES

Disassembly

1. Mount the steering gear housing in a vise and center the gear.
2. Remove the four shaft cover bolts (Fig. 12). Place a drain pan under the sector shaft.
3. Remove the sector shaft assembly and shaft cover. It may be necessary to lightly tap the end of the output shaft with a soft mallet to break the shaft cover loose.
4. Remove the shaft cover gasket and separate the shaft cover from the roller bearing assembly by removing the adjusting screw lock nut and turning the adjusting screw clockwise.
5. Remove the end plate bolts, the end plate and the shims.
6. Remove the lower bearing cup and ball bearing assembly by pressing on the end of the input shaft. If the bearing cup cocks, do not use force. Tap the bearing cup lightly in place and repeat the procedure.
7. Remove the upper bearing cup and ball bearing assembly.
8. Remove and discard the oil seals.

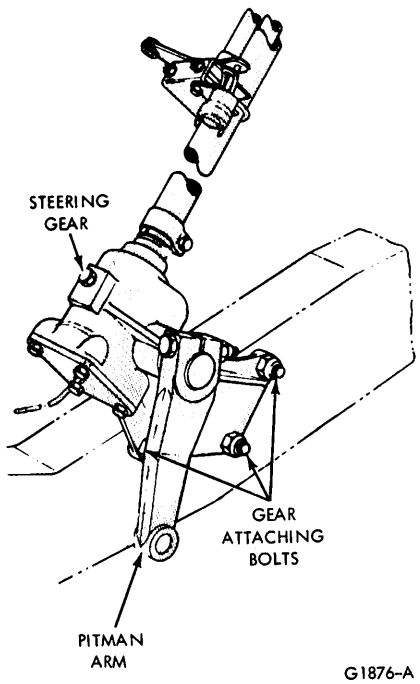

FIG. 5 Steering Gear Installation — P-Series

Assembly

If the sector shaft-to-bushing clearance exceeds .010 inch, replace them with Tool T61B-3576-A (Fig. 13).

1. Place the upper ball bearing assembly over the worm and input shaft assembly and into the upper bearing cup.
2. Insert the worm and shaft into the housing.
3. Place the lower ball bearing assembly on the worm and assemble the lower bearing cup.
4. Install the shims and worm cover to the housing and insert the cover bolts. Do not torque the bolts immediately but rotate the input shaft with one hand while tightening the worm cover bolts with the other to prevent damaging the worm bearing surfaces if the initial amount of shims is inadequate. When a light preload is obtained, torque the bolts to 18-22 ft-lb and check the preload.
5. Insert the adjusting screw into the shaft cover from inside and draw the roller bearing assembly into position until the shaft bottoms in the shaft cover. Reverse the adjusting screw rotation one full turn.
6. Position the gasket and shaft cover onto the housing, insert the cover bolts and torque to specification.
7. Install and tighten the adjusting screw lock nut to 16-20 ft-lb. Check preload.
8. Press in new shaft seals, fill the gear with lube and install the filler plug.

ALL MODELS EXCEPT F-100-250 (4 X 4), BRONCO AND P-SERIES

Disassembly

1. Mount the steering gear housing in a vise, then rotate the input shaft until it is centered.
2. Loosen the sector shaft adjusting screw lock nut.
3. Place a drain pan under the housing. Then loosen the end plate attaching screws so the end plate can be pulled away from the housing far enough to drain the lubricant.
4. Remove the screws that hold the sector cover (Fig. 14) on the housing. Then remove the cover and sector shaft as an assembly.
5. Remove the housing end plate, the worm lower bearing cup, and the lower bearing.
6. Remove the worm shaft through the bottom of the housing. Take the worm upper bearing off the shaft.
7. If required, remove the worm shaft upper bearing cup from the steering gear housing with the tool listed in Fig. 11.
8. If required, remove the sector shaft bushing or bearing and oil seal (Fig. 15) with the tool listed in Fig. 11.
9. Remove the worm shaft oil seal (Fig. 16).
10. Install the sector shaft and cover in a soft-faced vise, remove the adjusting screw lock nut, turn the adjusting screw in, and remove the

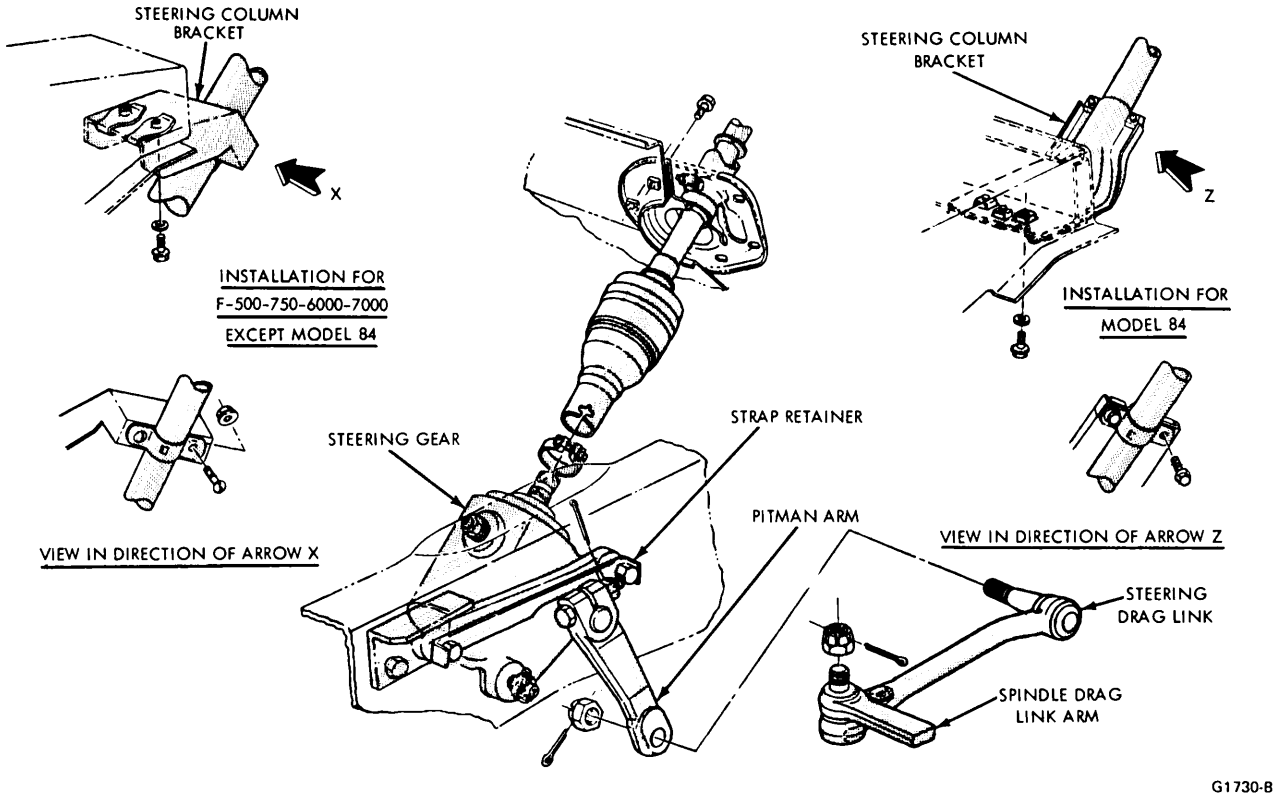

FIG. 6 Steering Gear Installation — F-B-500-750, 6000-7000

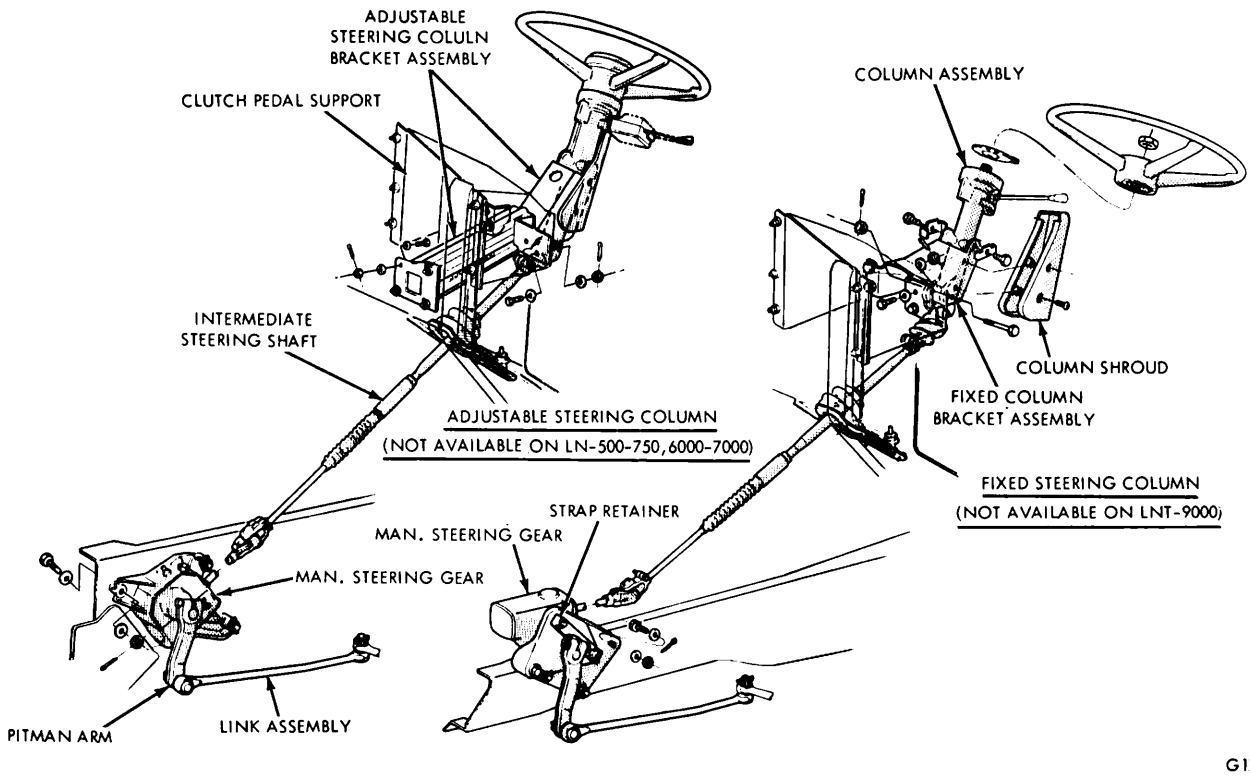

FIG. 7 Manual Steering Installation — L-N-500-900, 6000-9000, L-LT-LTS-LNT-800-900, 8000-9000

sector shaft from the cover.

11. If so equipped and if required, remove the sector shaft bushing or bearing from the cover (Fig. 17).

Assembly

1. If so equipped and if required, install a new bearing in the sector shaft cover (Fig. 18).
2. Install the sector shaft and adjusting screw in the cover, and install the lock nut loose.
3. If required, install a new sector shaft bushing or roller bearings in the sector shaft bushing or roller bearings in the steering gear housing (Fig. 15) with the tool shown in Fig. 11.
4. If required, install the worm shaft upper bearing cup in the housing with the tool shown in Fig. 11.
5. Position the worm shaft upper bearing on the worm, and then install the worm shaft in the housing.
6. Install the worm shaft lower bearing and cup.
7. Install the housing end plate using the same thickness of gaskets as was removed. Install the housing end plate bolts. See Specifications Section at the end of this Part for specified torque.
8. Check the worm bearing preload with an in-lb torque wrench. See worm bearing preload adjustment.
9. Lube and install the worm shaft seal with Tool T54L-6015-A.
10. Install the sector shaft and cover assembly in the housing using a new gasket. Lube and install the sector shaft seal with tool shown in Fig. 11. Lubricate the worm gear. Install sector shaft cover assembly bolts. See Specifications Section at the end of this Part for specified torque.
11. Center the input shaft to locate the high point. Check the worm mesh with an in-lb torque wrench and adjust as required. See the worm and roller mesh adjustment.
12. Remove the filler plug and fill the housing with the specified lubricant.

DESCRIPTION

STEERING GEAR

This integral power steering unit (Fig. 1) is a torsion-bar type of hydraulic assisted system. The system furnishes power to reduce the amount of turning effort required at the steering wheel. It also reduces road shock and vibrations.

The torsion bar power steering unit includes a worm and one-piece rack piston, which is meshed to the gear teeth on the steering sector shaft. The unit also includes a hydraulic valve, valve actuator, input shaft and torsion bar assembly which are mounted on the end of the worm shaft and operated by the twisting action of the torsion bar.

The torsion-bar type of power steering gear is designed with the one piece rack-piston, worm and sector shaft in one housing and the valve spool in an attaching housing (Fig. 1). This makes possible internal fluid passages between the valve and cylinder, thus eliminating all external lines and hoses, except the pressure and return hoses between the pump and gear assembly.

The power cylinder is an integral part of the gear housing. The piston is double acting, in that fluid pressure may be applied to either side of the piston.

A selective metal shim, located in the valve housing of the gear is for the purpose of tailoring steering gear efforts. If efforts are not within specifications they can be changed by increasing or decreasing shim thicknesses as follows:

Efforts heavy to the left-Increase shim thickness.

Efforts light to the left-Decrease shim thickness.

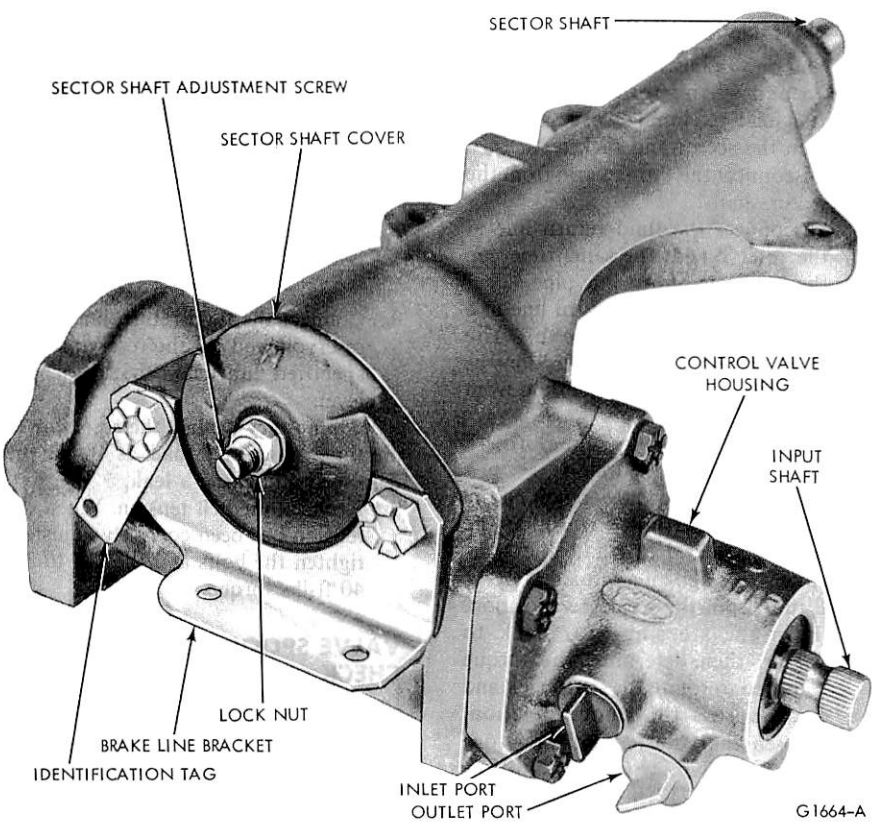

FIG. 1 Ford Integral Power Steering Gear

A change of one shim size will increase or decrease steering efforts approximately 2 in-lb.

As an example, the effort readings on a vehicle might be 17 in-lb to the left and 10 in-lb to the right: a difference of 7 in-lb. As stated previously, increasing one shim size will change the efforts 2 in-lb in **each** direction. Therefore, by changing to one size larger shim, the new gear efforts would be 15 in-lb left and 12 in-lb right. A two sizes larger shim would provide 13 in-lb left and 14 in-lb right. Either shim change would

bring the gear within the 4 in-lb maximum allowable difference. Ideally, the efforts should be exactly the same in each direction but this is not always possible. It is better though to have the effort slightly heavier to the right rather than to the left. In this example, increasing the shim two sizes would be the more satisfactory adjustment.

Shims are available in the following thicknesses and are notched on the outside diameter for identification:

0.0057-0.0063 inch 0 notch
0.0077-0.0083 inch 1 notch
0.0097-0.0103 inch 2 notches
0.0117-0.0123 inch 3 notches
0.0137-0.0143 inch 4 notches

A service identification tag is affixed to the gear assembly. It is located under the upper cover-to-housing bolt.

ADJUSTMENTS

MESH LOAD

During the vehicle breaking-in period, it is probable that some of the factory adjustments will change. These changes in adjustment do not necessarily affect the satisfactory operation of the steering gear assembly, and therefore ordinarily do not require readjustment unless there is excessive lash or other malfunctioning.

ADJUSTMENT IN VEHICLE

The only adjustment which can be performed is the total over center position load, to eliminate excessive lash between the sector and rack teeth.

1. Disconnect the Pitman arm from the sector shaft.
2. Disconnect the fluid return line at the reservoir, at the same time cap the reservoir return line pipe.
3. Place the end of the return line in a clean container and cycle the steering wheel in both directions as required, to discharge the fluid from the gear.
4. Turn the steering wheel to 45 degrees from the left stop.
5. Using an in-lb torque wrench on the steering wheel nut, determine the torque required to rotate the shaft slowly through an approximately 1/8 turn from the 45 degree position.
6. Turn the steering gear back to center, then determine the torque required to rotate the shaft back and forth across the center position. Loosen the adjuster nut, and turn the adjuster screw (Fig. 2) until the reading is 11-12 in-lb greater than the torque 45 degrees from the stop. Tighten the lock nut while holding the screw in place.
7. Recheck the readings and replace the Pitman arm and the steering wheel hub cover.

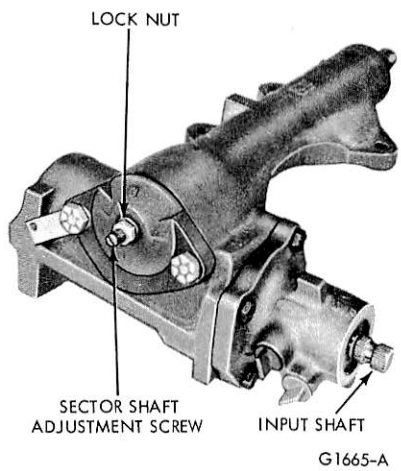

FIG. 2 Adjusting Mesh Load

8. Connect the fluid return line to the reservoir and fill the reservoir with specified lubricant to the proper level.

Do not pry against the reservoir to obtain proper belt load as it can be deformed and cause a leak.

9. Recheck the belt tension. When the tension has been correctly adjusted, tighten the bolts and the nut to 30-40 ft-lbs torque.

VALVE SPOOL CENTERING CHECK

1. Install a 0-2000 psi pressure gauge Tool T56L-33610-D in the pressure line between the power steering pump outlet port and the integral steering gear inlet port.
2. **Make sure that the valve on the gauge is in the fully open position.**
3. Check the fluid level in the reservoir and fill it to proper level with the specified fluid.
4. Start the engine and cycle the steering wheel from stop-to-stop, to bring the steering lubricant up to normal operating temperature. Stop the engine and recheck the reservoir. Add fluid if necessary.
5. With the engine running at approximately 1000 rpm and the steering wheel centered, attach an in-lb torque wrench to the steering wheel retaining nut. Apply sufficient torque to the torque wrench in each direction, either side of center, to get a gauge reading of 250 psi.
6. The torque reading should be the same in both directions when 250 psi is reached. If the difference between the readings exceeds 4 in-lbs, the steering gear must be removed and the valve centering shim removed from the valve housing and a thicker or thinner shim installed. **Two shims may be used but the combined thickness of the selected shims must not exceed .018 inch.** The piston must travel all the way to the stop without restriction or increase in worm turning effort. If two shims must be used to center the spool valve and a restriction or interference condition is experienced when turning the piston to its stop on the valve housing, the shaft and control assembly must be replaced. If the steering effort is heavy to the left, the shim thickness should be increased. Shim thickness should be decreased if the steering effort is light to the left.

The out of vehicle procedure for valve centering check is the same as for the vehicle except the torque and simultaneous pressure reading must be made at the right and left stops instead of either side of center.

REMOVAL AND INSTALLATION

STEERING GEAR

Removal

When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

1. Disconnect the pressure and the return lines from the steering gear. Plug the lines and the ports in the gear to prevent entry of dirt. The brake lines attached to the bracket on the steering gear must be removed.
2. Remove the two bolts that secure the flex coupling to the steering gear and to the column steering shaft assembly.
3. Raise the vehicle and remove the sector shaft attaching nut.
4. Remove the Pitman arm from the sector shaft with Tool T64P-3590-F. Remove the tool from the Pitman arm. Do not damage the seals.
5. If working on a vehicle equipped with a standard transmission, remove the clutch release lever retracting spring to provide clearance for removing the steering gear.
6. Support the steering gear then remove the three steering gear attaching bolts.
7. After removing the clamp bolt securing the flex coupling to the steering gear, work the steering gear free of the flex coupling and remove it from the vehicle.
8. If the flex coupling stayed on the input shaft, lift it off the shaft at this time.

Installation

1. Slide the flex coupling into place on the steering shaft assembly. Turn the steering wheel so that the spokes are in the horizontal position.
2. Center the steering gear input shaft.
3. Slide the steering gear input shaft into the flex coupling and into place on the frame side rail. Install the three attaching bolts and torque them to specification.
4. Make sure that the wheels are in the straight ahead position, then install the Pitman arm on the sector shaft. Install and tighten the sector shaft and install and tighten the attaching bolts to specification.
5. Move the flex coupling into place on the input and steering column shaft and install and tighten the attaching bolts to specification.
6. Connect and tighten the fluid pressure and the return line to the steering gear. Reinstall the brake lines to the bracket on the steering gear.
7. Remove the coil wire. Fill the power steering pump reservoir and, while engaging the starter, cycle the steering wheel to distribute the fluid. Check the fluid lever and add as required. Install the coil wire, start the engine and cycle the steering wheel. Check for fluid leaks.

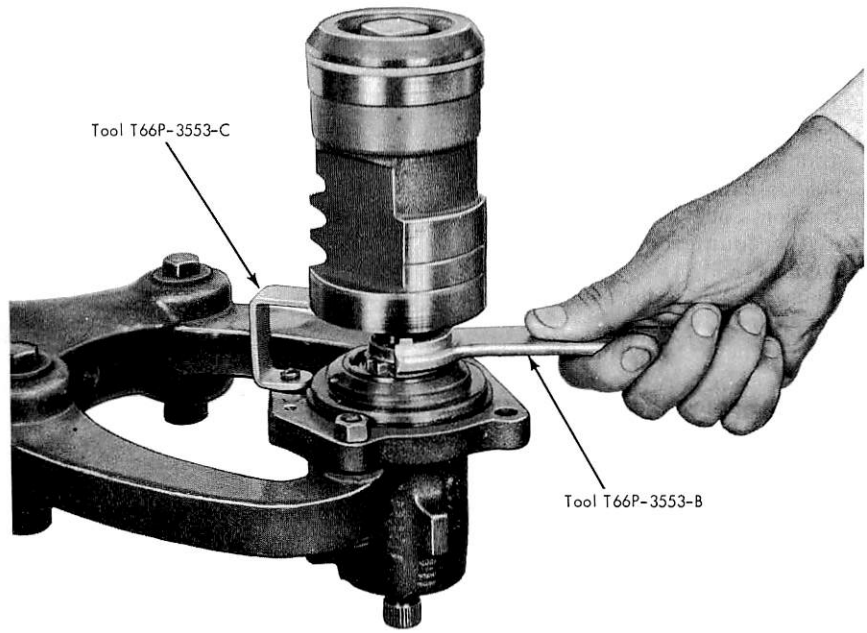

FIG. 3 Removing Worm Bearing Race Nut

VALVE CENTERING SHIM

Removal and Installation

1. Hold the steering gear over a drain pan in an inverted position and cycle the input shaft several times to drain the remaining fluid from the gear.
2. Mount the gear in a soft-jawed vise.
3. Turn the input shaft to either stop then, turn it back approximately 1 3/4 turns to center the gear.
4. Remove the two sector shaft cover attaching screws, the brake line bracket and the identification tag.
5. Tap the lower end of the sector shaft with a soft-faced hammer to loosen it, then lift the cover and shaft from the housing as an assembly. Discard the O-ring.
6. Remove the four valve housing attaching bolts. Lift the valve housing from the steering gear housing while holding the piston to prevent it from rotating off the worm shaft.
7. Remove the valve housing and the lube passage O-rings and discard them.
8. Place the valve housing, worm and piston assembly in the bench mounted holding fixture Tool T57L-500-A with the piston on the top.
9. Rotate the piston upward (back off) 3 1/2 turns.
10. Insert Tool T66P-3553-C (with the arm facing away from the piston) into a bolt hole in the valve housing. Rotate the arm into position under the piston (Fig. 3).
11. Loosen the Allen head race nut set screw from the valve housing.
12. Using Tool T66P-3553-B, loosen the worm bearing race nut.
13. Lift the piston-worm assembly from the valve housing. **During removal hold the piston to prevent it from spinning off at the shaft.**
14. Change the power steering valve centering shim.
15. Install the piston-worm assembly into the valve housing. **Hold the**

piston worm to prevent it from spinning off of the shaft.

16. Install the worm bearing race nut and torque to specification using Tool T66P-3553-B (Fig. 4).
17. Install the race nut set screw (Allen head) through the valve housing.
18. Rotate the piston upward (back off) 1/2 turn and remove Tool T66P-3553-C.
19. Remove the valve housing, worm, and piston assembly from the holding fixture.
20. Position a new lube passage O-ring in the counterbore of the gear housing.
21. Apply vaseline to the teflon seal on the piston.
22. Place a new O-ring on the valve housing.
23. Slide the piston and valve into the gear housing being careful not to damage the teflon seal.
24. Align the lube passage in the valve housing with the one in the gear housing, and install but do not tighten the attaching bolts.
25. Rotate the ball nut so that the teeth are in the same place as the sector teeth. Tighten the four valve housing attaching bolts to specification.
26. Position the sector shaft cover O-ring in the steering gear housing. Turn the input shaft as required to center the piston.
27. Apply vaseline to the sector shaft journal; then, position the sector shaft and cover assembly in the gear housing. Install the brake line bracket, steering gear identification tag and the two sector shaft cover attaching studs.
28. Position an in-lb torque wrench on the gear input shaft and adjust the meshload to approximately 4 in-lbs. Then, torque the sector shaft cover attaching studs to specification at the end of this Part.
29. After the cover attaching bolts have been tightened to specification, adjust the meshload to specification with an in-lb torque wrench.

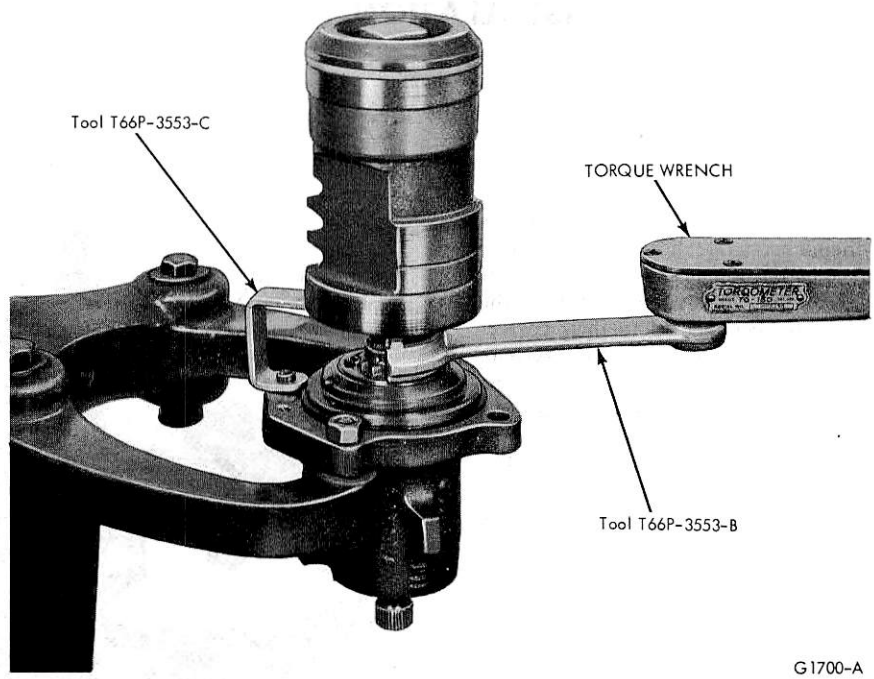

FIG. 4 Installing Worm Bearing Race Nut

DISASSEMBLY AND ASSEMBLY

In most cases, complete disassembly of the power steering gear will not be necessary. It is suggested that only those assemblies that are faulty be disassembled. Disassembly and reassembly of the unit and the subassemblies mustbe made on a clean workbench. As in repairing any hydraulically operated unit, cleanliness is of utmost importance. Therefore, the bench tools and parts must be kept clean at all times. Thoroughly clean the exterior of the unit with a suitable solvent and, when necessary, drain as much of the hydraulic oil as possible. Handle all parts very carefully to avoid nicks, burrs, scratches and dirt, which could make the parts unfit for use. Do not clean, wash or soak seals in cleaning solvent.

STEERING GEAR

Disassembly

1. Hold the steering gear over a drain pan in an inverted position and cycle the input shaft several times to drain the remaining fluid from the gear.
2. Mount the gear in a soft-jawed vise.
3. Remove the lock nut from the adjusting screw.
4. Turn the input shaft to either stop then, turn it back approximately 1 3/4 turns to center the gear.
5. Remove the two sector shaft cover attaching studs, the brake line bracket and the identification tag.
6. Tap the lower end of the sector shaft with a soft-hammer to loosen it, then lift the cover and shaft from the housing as an assembly. Discard the O-ring.
7. Turn the sector shaft cover counterclockwise off the adjuster screw.
8. Remove the four valve housing attaching bolts. Lift the valve housing from the steering gear housing while holding the piston to prevent it from rotating off the worm shaft. Remove the valve housing and the control valve gasket. Discard the gasket.
9. Stand the valve body and piston on end with the piston end down. Rotate the input shaft counterclockwise out of the piston allowing the ball bearings to drop into the piston.
10. Place a cloth over the open end of

the piston and turn it upside down to remove the balls.
11. Remove the two screws that attach the ball guide clamp (Fig. 5) to the ball nut and remove the clamp and the guides.
12. Install the valve body assembly in the holding fixture (do not clamp in a vise) and loosen the race nut screw (Allen head) from the valve housing and remove the worm bearing race nut as shown in Fig. 3.
13. Carefully slide the input shaft, worm and valve assembly out of the valve housing. Due to the close diametrical clearance between the spool and housing, the slightest cocking of the spool may cause it to jam in the housing.
14. Remove the shim from the valve housing bore.

Assembly

Do not clean, wash, or soak seals in cleaning solvent.

1. Mount the valve housing in the holding fixture with the flanged end up.
2. Place the required thickness valve spool centering shim (Fig. 5) in the housing.
3. Carefully install the worm and valve in the housing.
4. Install the race nut in the housing and torque it to specification at the end of this Part.
5. Install the race nut set screw (Allen head) through the valve housing and torque to specification at the end of this Part.
6. Place the piston on the bench with the ball guide holes facing up. Insert the worm shaft into the piston so that the first groove is in alignment with the hole nearest to the center of the piston (Fig. 6).
7. Place the ball guide in the piston. Place the 27 to 29 balls, depending on the piston design, in the ball guide (Fig. 6) turning the worm in a clockwise direction as viewed from the input end of the shaft. If all of the balls have not been fed into the guide upon reaching the right stop, rotate the input shaft in one direction and then in the other while installing the balls. After the balls have been installed, do not rotate the input shaft or the piston more than 3 1/2 turns off the right stop to prevent the balls from falling out of the circuit.
8. Secure the guides in the ball nut with the clamp (Fig. 6).
9. Apply vaseline to the teflon seal on the piston.
10. Place a new control valve gasket on the valve housing.
11. Slide the piston and valve into the gear housing being careful not to damage the teflon seal.
12. Align the lube passage in the valve housing with the one in the gear housing, and install but do not tighten the attaching bolts.
13. Rotate the ball nut so that the teeth are in the same plane as the sector teeth. Tighten the four valve housing attaching bolts to specifications.
14. Position the sector shaft cover O-ring in the steering gear housing. Turn the input shaft as required to center the piston.
15. Apply vaseline to the sector shaft journal then position the sector shaft and cover assembly in the gear housing. Install the brake line bracket, the steering identification tag and two sector shaft cover attaching bolts. Torque the bolts to specifications.
16. Attach an in-lb torque wrench to the input shaft. Adjust the mesh load to specifications as shown in Fig. 2.

STEERING GEAR HOUSING

Disassembly and Assembly

1. Remove the snap ring and the spacer washer (Fig. 7) from the lower end of the steering gear housing.
2. Remove the lower seal from the housing as shown in Fig. 8. Lift the spacer washer from the housing.
3. Remove the upper seal in the same manner as the lower seal. Some housings require only one seal and one spacer.
4. Dip both sector shaft seals in gear lubricant.
5. Apply lubricant to the sector shaft seal bore of the housing and position the sector shaft inner seal into the housing with the lip facing inward. Press the seal into place with the tool shown in Fig. 9. Place a spacer washer (0.090 inch) on top of the seal and apply more lubricant to the housing bore.
6. Place the outer seal in the housing with the lip facing inward and press it into place as shown in Fig. 10. Then, place a 0.090 inch spacer washer on top of the seal.
7. Position the snap ring in the housing. Press the snap ring into the housing to properly locate the seals and engage the snap ring in the groove.

VALVE HOUSING

Disassembly and Assembly

1. Remove the dust seal (Fig. 11) from the rear of the valve housing with Tools T59L-100-B and T58L-101-A and discard the seal.
2. Remove the snap ring from the valve housing.
3. Turn the fixture to place the valve housing in an inverted position.
4. Insert special tool in the valve body assembly opposite the seal end and gently tap the bearing and seal out of the housing as shown in Fig. 12. Discard the seal. **Caution must be exercised when inserting and removing the tool to prevent damage to the valve bore in the housing.**
5. Remove the fluid inlet and outlet tube seats with an EZ-out if they are damaged.
6. Coat the fluid inlet and outlet tube seats with vaseline and position them in the housing. Install and tighten the tube nuts to press the seats to the proper location.
7. Coat the bearing and seal surface of the housing with a film of vaseline.
8. Position the bearing in the valve housing. Seat the bearing in the valve housing with the tool shown in Fig. 13. Make sure that the bearing is free to rotate.
9. Dip the new oil seal in gear lubricant; then, place it in the housing with the metal side of the seal facing outward. Drive the seal into the housing until the outer edge of seal does not quite clear the snap ring groove (Fig. 14).
10. Place the snap ring in the housing; then, drive on the ring with the tool shown in Fig. 14 until the snap ring seats in its groove to properly locate the seal.
11. Place the dust seal in the housing with the dished side **(rubber side) facing out.** Drive the dust seal into place with the tool shown in Fig. 14. The seal must be located behing the undercut in the input shaft when it is installed.

WORM AND VALVE

Disassemlby and Assembly

1. Remove the snap ring and actuator spring from the end of the actuator.
2. Slide the control valve spool (Fig. 5) off the actuator.
3. Install the valve spool evenly and slowly with a slight oscillating motion into the flanged end of valve housing with the valve identification groove between the valve spool lands outward, checking for freedom of valve movement within the housing working area. The valve spool should enter the housing bore freely and fall by its own weight.
4. If the valve spool is not free, check

for burrs at the outward edges of the working lands in the housing and remove with a hard stone.
5. Check the valve for burrs and if burrs are found, stone the valve in a **radial direction only.** Check for freedom of the valve again.
6. Remove the valve spool from the housing.
7. Slide the spool onto the actuator making sure that the groove in the spool annulus is toward the worm.
8. Install the actuator spring and the snap ring to retain the spool. The actuator spring convex side (color coded) must be toward the snap ring. The beveled ID of the snap ring must be assembled away from the spool.

PISTON AND BALL NUT

Disassembly and Assembly

1. Remove the teflon ring and the O-ring (Fig. 5) from the piston and ball nut.
2. Dip a new O-ring in gear lubricant and install it on the piston and ball nut.
3. Install a new teflon ring on the piston and ball nut being careful not to stretch it any more than necessary.

DESCRIPTION

STEERING GEAR

The Rotary Valve Safety power steering gear operates entirely on displacing fluid to provide hydraulic fluid pressure assists only when turning. As the entire gear assembly is always full of fluid, all internal components of the gear are immersed in fluid making periodic lubrication unnecessary. In addition, this fluid acts as a cushion to absorb road shocks that may be transmitted to the driver. All fluid passages are internal except the pressure and return hoses between the gear and pump.

The rotary valve provides a smooth transmission through the driving range of steering wheel effort. A torsion bar transmits the road feel to the driver. Response of the steering gear to effort applied to the steering wheel has been greatly increased.

The rack-piston nut is one piece and is geared to the sector shaft. Lash between the sector shaft and rack-piston nut is maintained by an adjusting screw which is retained in the end of the shaft gear (Fig. 1).

ADJUSTMENTS

During the breaking in period of the vehicle, it is probable that some of the factory adjustments will change. These changes in adjustment do not necessarily affect the satisfactory operation of the steering gear assembly and ordinarily do not require re-adjustment unless there is excessive lash or other malfunctioning. The only adjustment that should be performed in the vehicle is the total over center position load (mesh load) to eliminate excessive lash between the sector shaft and rack teeth.

MESH LOAD

1. Disconnect the Pitman arm from the sector shaft and remove the steering wheel hub.
2. Disconnect the fluid return line at the reservoir; at the same time cap the reservoir return line pipe.
3. Place the end of the return line in a clean container and cycle the steering wheel in both directions as required, to discharge the fluid from the gear.
4. Turn the gear 1/2 turn off center (either direction). Using a 24 in-lb torque wrench on the steering wheel nut, determine the torque required to rotate the shaft slowly through a 20 degree arc.
5. Turn the gear back to center and repeating the method of reading torque as in Step 4, above, loosen the adjuster lock nut, turn the screw inward with a 7/32-inch Allen wrench until the reading is equal to 6 in-lbs in excess of Step 4 above, and retighten the lock nut while holding the screw in place.
6. Recheck the readings and replace the Pitman arm and the steering wheel hub.
7. Connect the fluid return line to the reservoir and fill the reservoir with D2AZ-19580-A fluid to the proper level.

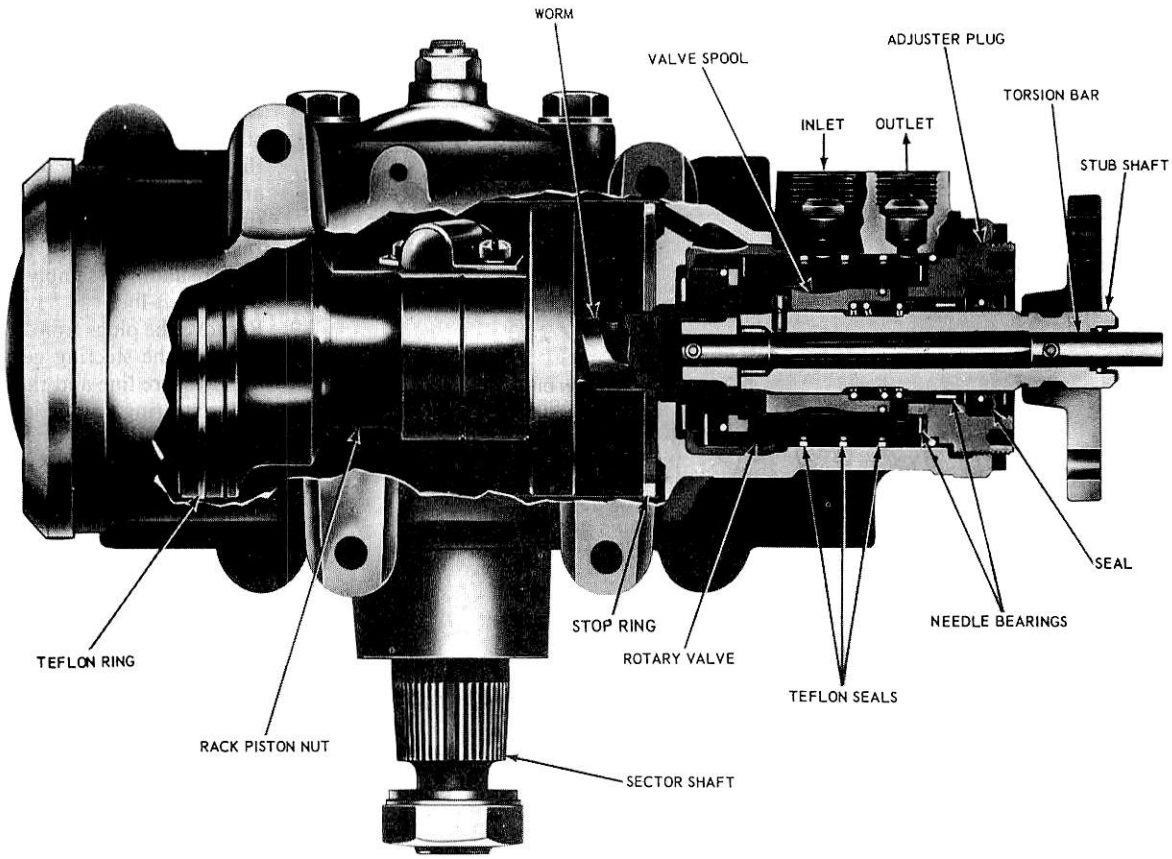

FIG. 1 Power Steering Gear—Sectional View

REMOVAL AND INSTALLATION

STEERING GEAR

Removal

When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

1. Position a drain pan under the steering gear. Disconnect the pressure and the return lines from the steering gear. Plug the lines and the ports in the gear to prevent entry of dirt.
2. Raise the vehicle on a hoist and remove the pitman arm attaching nut and lock washer.
3. Remove the pitman arm from the sector shaft with Tool T64P-3590-F.
4. Remove the 3 steering gear-to-frame side rail attaching bolt nuts and lower the vehicle.
5. Remove the pinch bolt from the flange and insulator assembly.
6. Loosen the nut retaining the horn and pivot the horn outboard.
7. Remove the 3 steering gear attaching bolts and remove the steering gear and shaft and joint assemblies as a unit.
8. Remove the pinch bolt and nut from the shaft and joint assembly (Fig. 2).
9. Remove the shaft and joint assembly from the steering gear.

Installation

1. Attach the shaft and joint assembly to the steering gear. Install the pinch bolt and torque the nut to 45-60 ft-lb. This operation should be

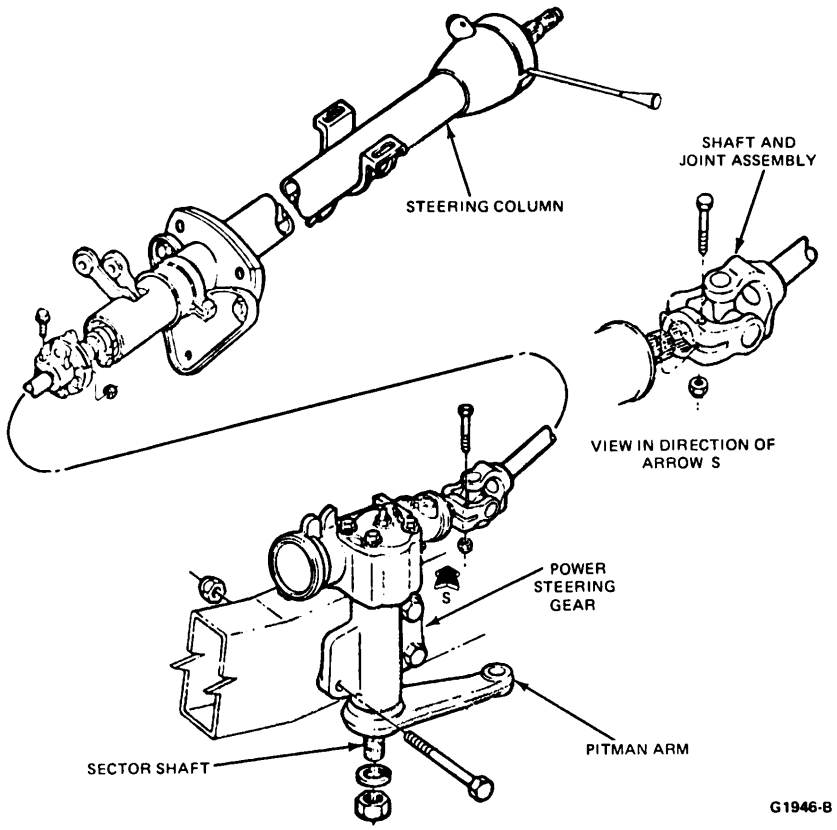

FIG. 2 Power Steering Gear Installation—Bronco

performed prior to gear installation.
2. Place the vehicle on a hoist. POsition the steering gear to the frame side rail and attach the one forward attaching bolt and nut loosely.
3. Center the steering gear input shaft.
4. Position the shaft of the shaft and joint assembly into the flange and insulator assembly while supporting the rear of the steering gear.
5. Position the remaining two steering gear attaching bolts through the steering gear flange and through the frame side rail.
6. Attach the two remaining steering gear attaching nuts and torque all three attaching nuts to 52-90 ft-lb.
7. Make sure the wheels are in a straight ahead position and install the pitman arm, lock washer and nut and torque to 170-230 ft-lb. Lower the vehicle.
8. Install the pinch bolt to the flange and insulator assembly and torque to 28-35 ft-lb.
9. Remove the plugs from the lines and ports of the steering gear. Connect the pressure line and the return line to the steering gear. Torque to 16-25 ft-lb.
10. Pivot the horn inboard and tighten the retaining nut. Remove the coil wire. Fill the power steering pump reservoir and while engaging the starter, cycle the steering wheel to distribute the fluid. Check the fluid level and add as required. Install the coil wire, start the engine and cycle the steering wheel. Check for fluid leaks.

DISASSEMBLY AND ASSEMBLY

Disassembly and reassembly of the unit and the subassemblies must be made on a clean workbench. As in repairing any hydraulically operated unit, cleanliness is of utmost importance. Therefore, the bench, tools, and parts must be kept clean at all times. Thoroughly clean the exterior of the gear with a suitable solvent and, when necessary, drain as much of the hydraulic fluid from the gear as possible. Do not clean, wash or soak seals in cleaning solvent.

STEERING GEAR

Disassembly

1. Mount the steering gear in a vise (Fig. 3).
2. Rotate the end plug retaining ring to place one end of the ring opposite the hole in the housing.
3. Working through the hole in the housing (Fig. 4), unseat the retaining ring then work it out of the groove with a screwdriver.
4. Rotate the input shaft in a counterclockwise direction using a 3/4 inch, 12-point socket wrench to force the end plug out of the housing. Do not rotate the shaft any more than necessary to remove the plug. Further rotation will allow the balls to fall from their circuit and allow the rack-piston to become disengaged from the sector shaft. Remove the O-ring from the housing and discard it.
5. Rotate the input shaft 1/2 turn in a clockwise direction to draw the piston inward.
6. Turn the end plug (Fig. 5) counterclockwise out of the piston with a 1/2-inch drive extension.
7. Remove the lock nut from the sector shaft adjustment screw. Discard the nut.
8. Remove the four cover attaching screws. Rotate the sector shaft adjustment screw with an Allen wrench until the cover is free of the housing. Remove the cover and the O-ring. Discard the O-ring.
9. Turn the input shaft as required to center sector shaft teeth in the housing.
10. Tap the end of the sector shaft with

a soft-faced hammer to free it from the housing.

11. Remove the adjuster plug lock nut.
12. Remove the adjuster plug with spanner wrench T65P-3A537-A (Fig. 6).
13. Insert the tool shown in Fig. 7 into the end of the rack-piston until it contacts the worm shaft. Rotate the stub shaft in a counterclockwise direction until the worm is free of the rack-piston. Withdraw the rack-piston from the housing making sure that the tool is held all the way in the piston to prevent dropping the balls. Do not disassemble the rack-piston at this time.
14. Pull the stub shaft and valve assembly from the housing.
15. Lift the worm, lower thrust bearing and the races from the housing.

Assembly

1. Secure the steering gear housing in a vise.
2. Lubricate the worm shaft, lower thrust bearing, and races with steering gear fluid; then, position the thrust bearing and races on the worm.

Align the valve body drive pin on the worm, with the narrow pin slot in the valve body. Be sure O-ring seal between the valve body and the worm head is installed. Lubricate the teflon ring and lower cap O-ring with petrolatum.

3. Position the valve assembly and the worm shaft in the housing as a unit (Fig. 8). Do not push against the stub shaft as this could cause the stub shaft and cap to pull out of the valve body, allowing the spool seal to slip into valve body fluid grooves. Install the valve assembly by pushing on the outer diameter of the valve body housing with the finger tips. Be sure that the teflon rings are not binding inside the housing. The valve assembly is correctly seated when the fluid return hole in the gear housing is fully visible.
4. Place the tool shown in Fig. 9 over the end of the stub shaft.
5. Lubricate a new adjuster plug O-ring with petrolatum and install it in the adjuster plug groove.
6. Install the adjuster plug over the end of the stub shaft and tighten it just enough to be sure all parts are properly seated. Remove Tool T65P-3A537-B.
7. Install the adjuster plug locknut loosely on the plug.
8. Tighten the adjuster plug with wrench T65P-3A537-A while rotating the input shaft. As soon as additional drag is noted, back the adjuster plug off 1/8 turn. Measure the input shaft drag with an in-lb torque wrench.
9. Tighten the adjuster plug (Fig. 10) to obtain a 1-3 in-lb preload in excess of the drag that was measured previously. Tighten the adjuster plug lock nut and recheck the thrust bearing preload. Total preload must not exceed 8 in-lbs.
10. Install Tool T65P-3805-A in the steering gear housing. Position the rack-piston as shown in Fig. 11. Be sure that Tool T65P-3D517-A is contacting the worm shaft. Push the rack-piston inward until it contacts the worm shaft while keeping pressure applied to Tool T65P-3D517-A. Turn the stub shaft clockwise until the middle rack groove in the rack-piston is aligned with the center of sector shaft roller bearing. Remove the tool from the housing.
11. Lubricate a new O-ring with C1AZ-19582-A and position it in the sector shaft cover.
12. Thread the sector shaft cover on the adjusting screw until it bottoms then back it off 1-1/2 turns.
13. Install the sector shaft so that the center gear tooth meshes with the center groove in the rack-piston. Be sure that the cover O-ring is in place before pushing the cover down on the housing.
14. Install the cover screws and lock washers. Tighten to 30-35 ft-lbs.
15. Install a new adjuster lock nut halfway on the adjuster screw.
16. Install the end plug in the rack-piston. Tighten the plug to 50-100 ft-lbs torque.

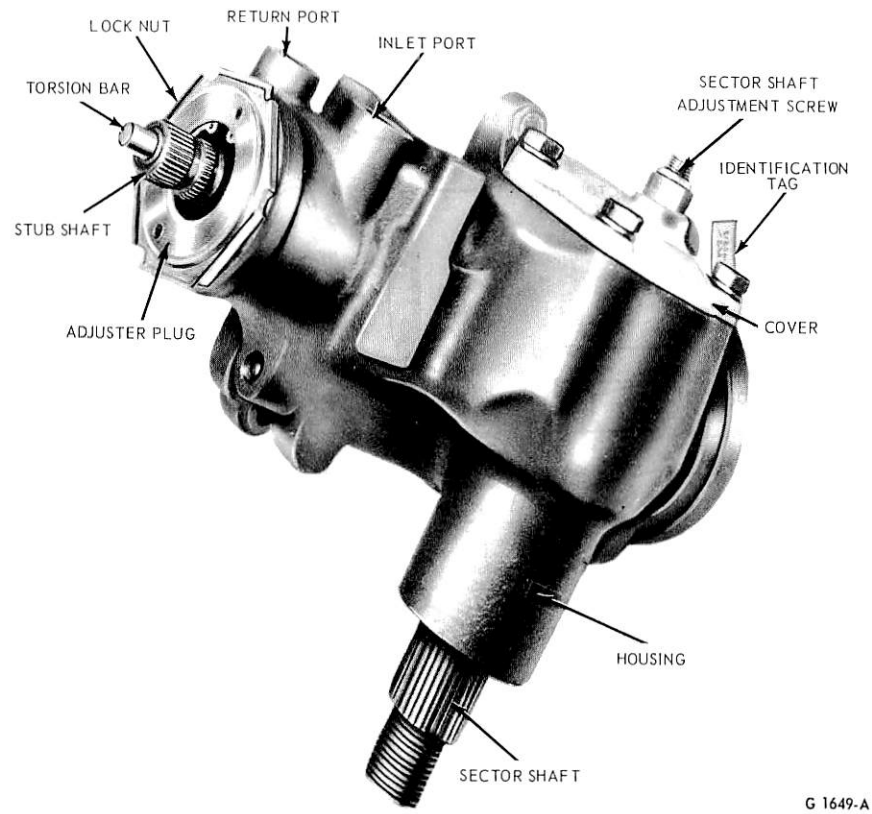

FIG. 3 Steering Gear—Exterior View

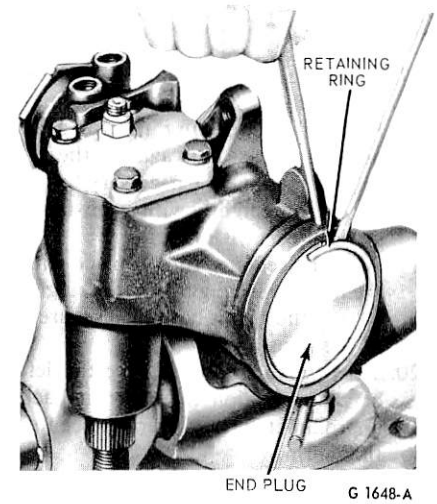

FIG. 4 Removing End Plug Retaining Ring

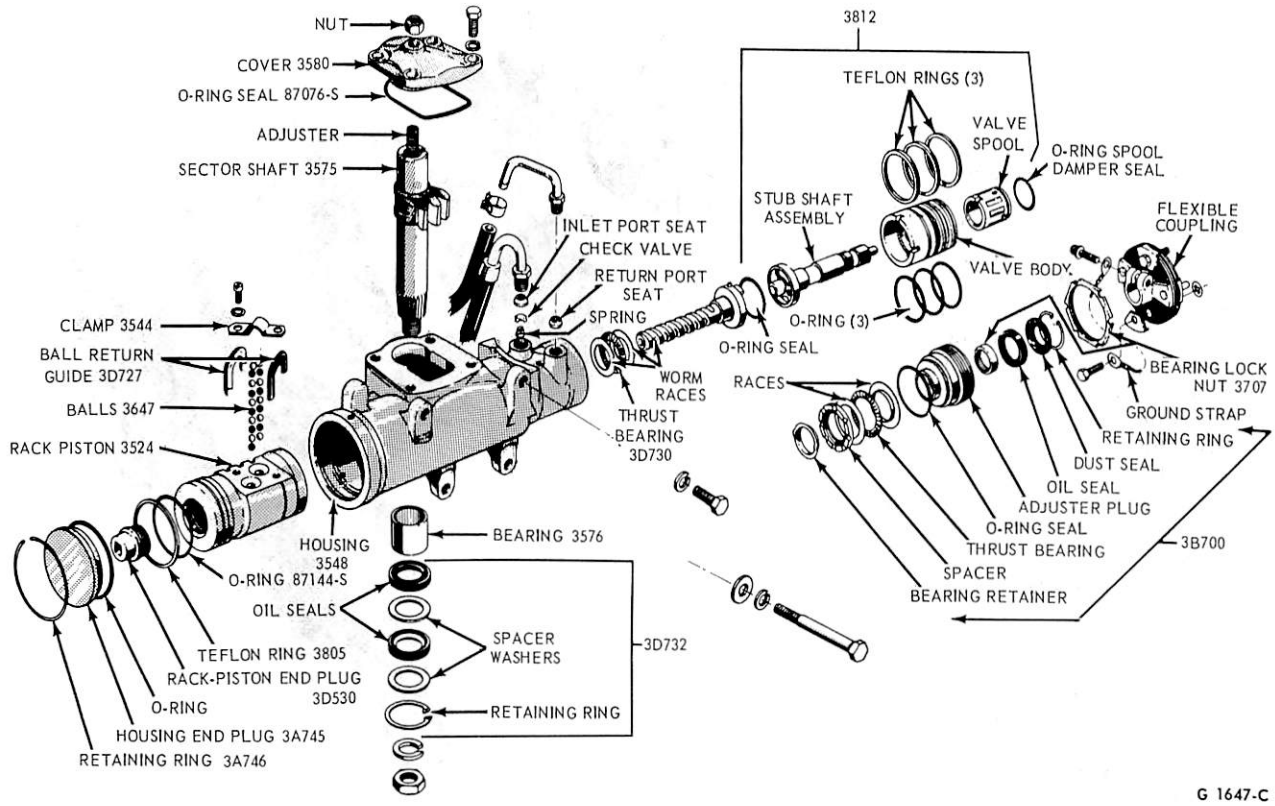

FIG. 5 Steering Gear Disassembled

17. Lubricate a new housing end plug O-ring and install it in the housing.
18. Place the end plug in the gear housing and seat it against the O-ring seal. It may be necessary to tap the end plug lightly with a soft-faced mallet to seat it properly.
19. Snap the retainer ring in place with the fingers. Tap lightly on the ring to be sure the ring is bottomed securely in the housing.
20. Turn the input shaft to the full left or right position then turn it back approximately 1-3/4 turns to center the worm.
21. Place an in-lb torque wrench on the input shaft as shown in Fig. 12.
22. With the gear on center and the sector shaft adjuster backed off, measure the total drag. With the gear on center, adjust the sector shaft thrust screw so that preload is 4-8 in-lbs in excess of total preload and drag. Readings are to be made through an arc not exceeding 20 degrees with the gear on center. Tighten the lock nut.
23. After obtaining the proper mesh load, tighten the sector shaft adjustment screw lock nut to 30-35 ft-lbs.

STEERING GEAR HOUSING

Disassembly and Assembly

1. Remove the snap ring (Fig. 13) that secures the sector shaft seals in the lower end of the housing. Remove the lower spacer washer.
2. Remove the lower seal (double lip), spacer washer, upper seal (single lip) with Tools T58L-101-A and T59L-100-B (Fig. 14).
3. Check the housing bearing for wear and remove the bearing only if worn or damaged. Working from the lower end of the housing (Fig. 15) press the bearing out of the housing. Discard the bearing.
4. Working from the upper end of the housing, press in a new bearing until the upper end is 0.030 inch below the housing bore. When installing the bearing, make sure it is pressed in from the identification end (stamped end).
5. Lubricate new sector shaft seals (Fig. 11) in D2AZ-19582-A hydraulic fluid. Install the single lip seal first, then a back-up washer. Using special tool (Fig. 16), drive the seal and washer in far enough to provide clearance for the other seal

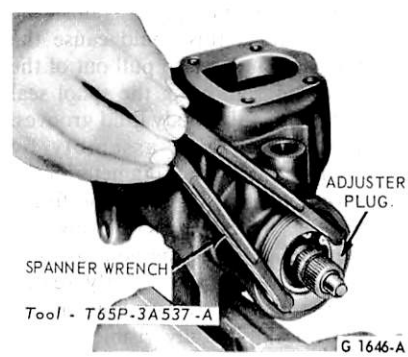

FIG. 6 Removing Adjuster Plug

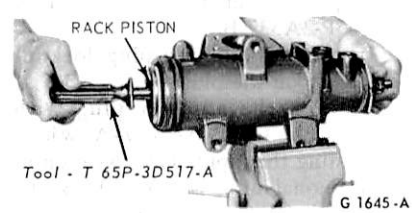

FIG. 7 Removing Rack Piston

and back-up washer and the retaining ring. The seal must not bottom on the end of the counterbore. Install the double lip seal and the second back-up washer. Again using the special tool, drive the seal and back-up washer in only far enough to provide clearance for the retaining ring. Install the sector shaft seal retaining ring with snap ring pliers, making certain that the ring is seated properly.

6. To remove a damaged port seat, use a 5/16-18 inch U.S. thread (coarse) tap and turn it two turns into the seat. Coat the end of the tap with petrolatum to prevent chips from entering the passage while tapping the seat.
7. Thread a bolt and nut with a flat washer into the tapped hole (Fig. 17).
8. Hold the bolt from turning and tighten the nut to extract the seat. Discard the seat.
9. Remove the check valve and spring from the inlet port.
10. Position the spring, check valve and new seat in the inlet port.
11. Use the tool shown in Fig. 18 and drive the seat into place.
12. Install the outlet port seat in the same manner.
13. A stop ring is located in the piston bore to limit piston travel. Do not attempt to remove this ring. If the stop ring is damaged, it will be necessary to replace the housing assembly.

ADJUSTER PLUG

Disassembly and Assembly

1. Lift the adjuster plug off the stub shaft (Fig. 5).
2. Pry the thrust bearing retainer off the adjuster plug as shown in Fig. 19. Be careful not to score the needle bearing bore. Discard the retainer.
3. Lift the spacer, thrust bearing, races and the O-ring, from the plug (Fig. 20). Discard the O-ring.
4. If necessary to replace the roller bearing, remove the dust seal retaining ring. Working from the spacer end of the adjuster plug, remove the roller bearing, oil seal and the dust seal as shown in Fig. 21. If the roller bearing does not need replacing do not remove it. Pry the dust seal and the oil seal from the adjuster plug with a screwdriver.
5. Place a new roller bearing on the tool shown in Fig. 21 with the bearing manufacturer's identification facing toward the tool.
6. Position the bearing and tool in the bore. Drive the bearing into the plug until it is flush with the bottom surface of the stub shaft seal bore.
7. Lubricate a new oil seal with D2AZ-19582-A. Install the seal with Tool T65P-3D526-A pressing it into the plug far enough to provide clearance for the dust seal and the snap ring (Fig. 22).
8. Lubricate a new dust seal with D2AZ-19580-A and install it with its smooth rubber surface facing outward.
9. Secure the dust seal with the ring, making sure that the ring is properly seated.
10. Lubricate a new O-ring seal with vaseline and install it on the adjuster plug.
11. Assemble the thrust bearing outer race, thrust bearing, inner race, and the thrust bearing spacer on the adjuster plug (Fig. 20).
12. Install a new bearing retainer on the adjuster by **carefully** tapping on the flat surface of the retainer (Fig. 23).

STUB SHAFT AND ROTARY VALVE ASSEMBLY

Disassembly

Disassembly of the valve (Fig. 24) is not recommended unless the valve components require cleaning due to

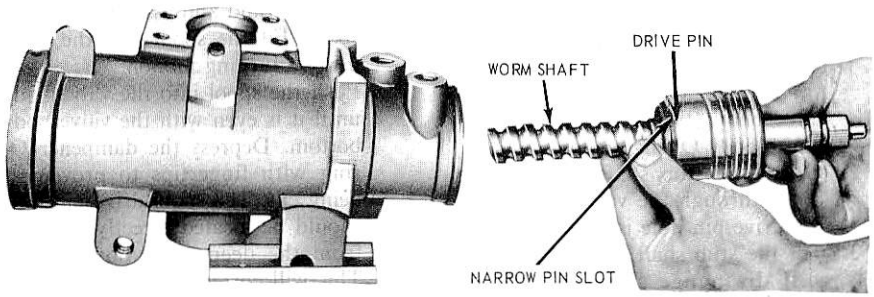

FIG. 8 Installing Valve and Worm Shaft in Housing

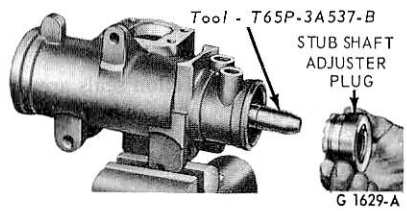

FIG. 9 Installing Adjuster Plug

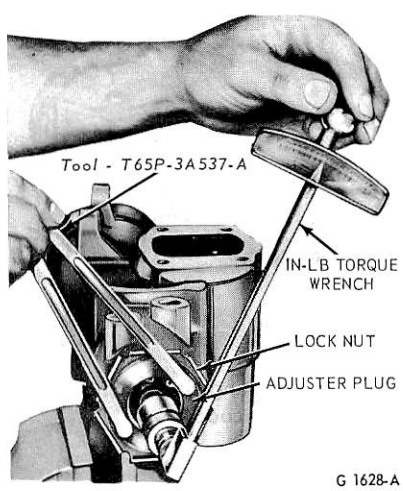

FIG. 10 Adjusting Thrust Preload

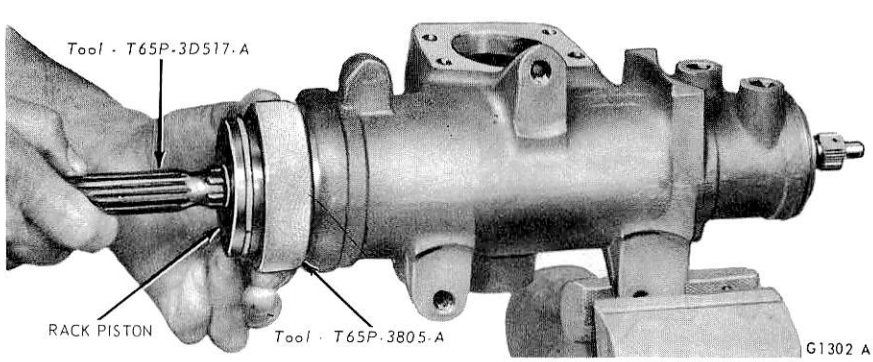

FIG. 11 Installing Rack-Piston

system contamination or replacement of the dampener O-ring.

1. Invert the valve and tap on the work bench (torsion bar end) until the torsion bar cap separates from the valve body (Fig. 25). Discard the cap-to-body O-ring.
2. Grasp the stub shaft and push it down through the valve body until the drive pin hole is visible.
3. Tilt the stub shaft so the drive pin will disengage from the spool. Remove the stub shaft from the valve body and spool assembly.
4. Slide the spool out of the top of the valve body. Do not attempt to remove the spool through the bottom as it may hang up or be damaged.

Assembly

The O-ring and Teflon seals are the only components which can be replaced.

1. Dip the dampener O-ring in power steering fluid and assemble to the spool. Fit the spool into the body using a turning motion.
2. Push the spool into the valve body until it is even with the valve body bottom. Depress the dampener O-ring with fingertips to prevent it being cut. The spool drive pin hole should be located directly opposite from the deep valve body notch. This will correctly position the cap notch to the body pin.
3. Insert the stub shaft into the spool with the stub shaft drive pin lined up with the mating spool hole.
4. Insert the drive pin into the spool hole and pull the assembly into the valve body keeping the cap slot and body pin aligned. When the cap seats correctly in the valve body, the top surface of the cap should be at least 3/32 inch below the deep body notch.
5. Replace the cap-to-body O-ring.

RACK PISTON

Disassembly and Assembly

1. Cut the Teflon ring and the O-ring from the piston.
2. Place the assembly on a clean lintfree cloth and remove the screws that attach the ball return guide clamp to the rack-piston and remove the clamp (Fig. 26).
3. Lift the ball return guides from the rack-piston.
4. Remove Tool T65P-3D517-A from the piston and remove the remaining balls.
5. Thoroughly clean all parts.
6. Lubricate a new O-ring and Teflon ring. Install the O-ring on the piston being careful not to twist it. Slide the Teflon ring into place being careful not to stretch it any more than necessary.
7. Slide worm (Fig. 27) fully into the rack-piston. Load 16 balls into the guide hole nearest the Teflon ring while slowly rotating the worm counterclockwise to feed the balls through circuit. Alternate the dark colored balls with the polished balls through the circuit.

Apply petrolatum liberally to one of the ball return guides and install the remaining balls in the guide. The constant ratio gear requires 22 balls while the variable ratio gear has 24 balls total. Place the other half of the guide in

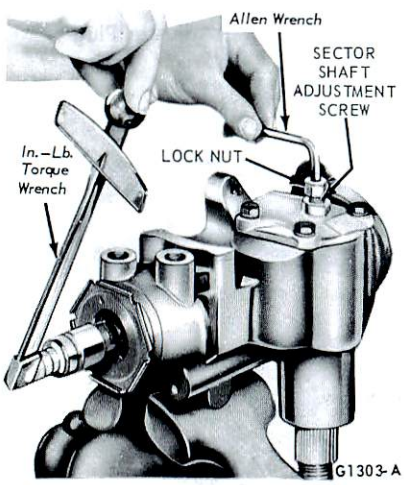

FIG. 12 Adjusting Sector Shaft Mesh Load

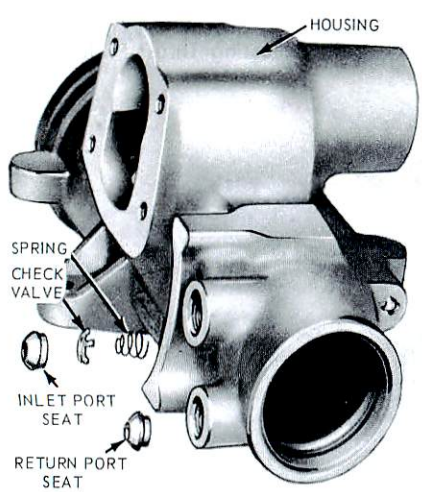

FIG. 13 Steering Gear Housing Disassembled

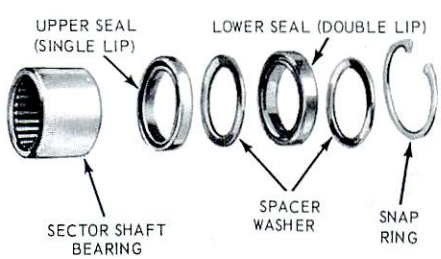

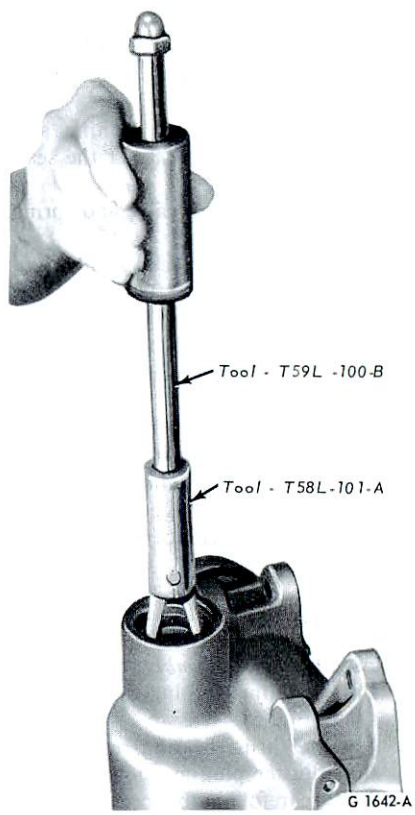

FIG. 14 Removing Sector Shaft Seals

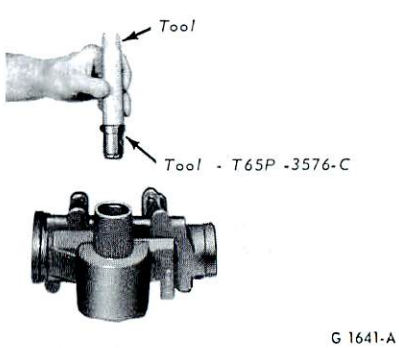

FIG. 15 Removing Sector Shaft Bearings

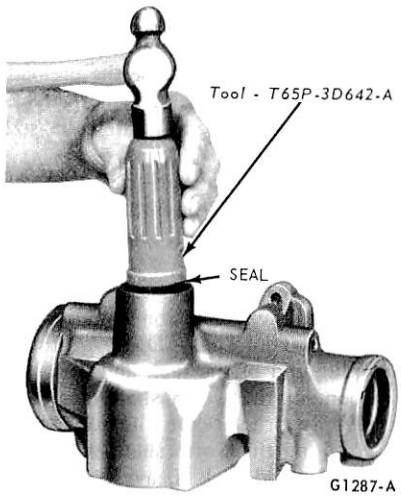

FIG. 16 Installing Sector Shaft Seal

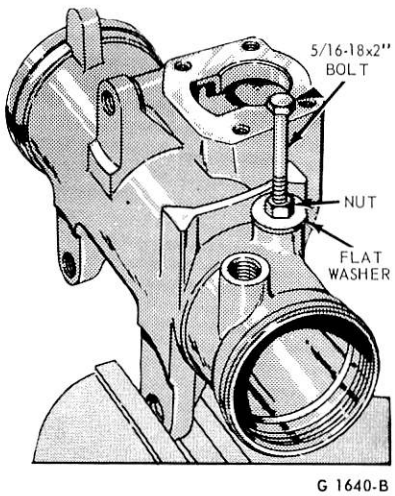

FIG. 17 Removing Port Seal

position and insert them into holes in the rack-piston. Be sure that the dark ball in the guide is installed next to the polished ball in the rack-piston. Install the ball return guide clamp with screws and lock washers. Tighten the screws to specification.

8. The worm groove is ground with a high point in the center. When the rack-piston passes over this high point there should be a preload of 1-4 in-lbs. Clamp the rack-piston in a vise with soft jaws with the worm shaft pointing up. To avoid distortion, do not tighten the vise too tight.
9. Place the valve assembly on the worm, engaging the worm drive pins. Rotate the worm until it extends 1-1/4 inch from the rack-piston to the thrust bearing face. This is the center position.
10. Place an in-lb torque wrench with a 3/4 inch deep wall 12-point socket on the stub shaft, and rotate the wrench through an arc of approximately 60 degrees in both directions several times, then take a torque reading. The highest average reading obtained with the worm rotating should be between 1-4 in-lbs.
11. If this reading is too high or too low a new set of balls should be installed. Service replacement balls are available in the sizes shown in Fig. 28.

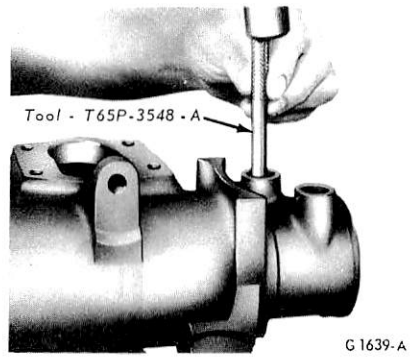

FIG. 18 Installing Inlet Port Seat

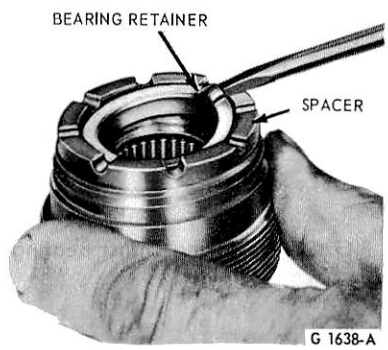

FIG. 19 Removing Thrust Bearing Retainer

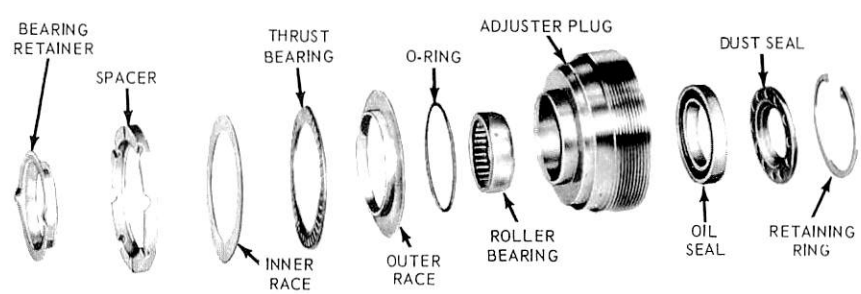

FIG. 20 Adjuster Plug Disassembled

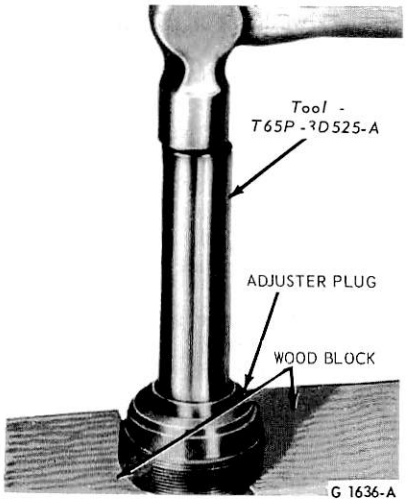

FIG. 21 Removing or Installing Roller Bearing from Adjuster Plug

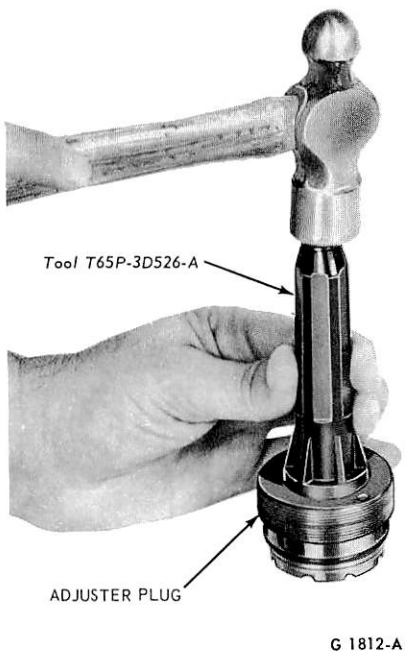

FIG. 22 Installing Oil Seal in Adjuster Plug

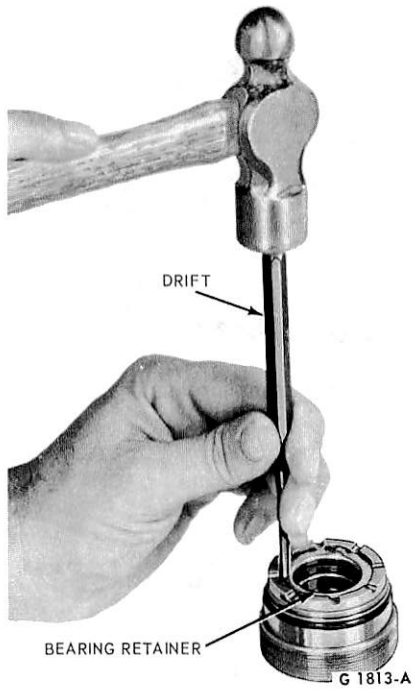

FIG. 23 Installing Thrust Bearing Retainer

12. Note the ball size stamped on the rack piston and install the next size larger balls to increase the preload. If no number is stamped on the rack-piston, the original ball code size was No. 7.

A change of one ball size larger will increase the preload approximately one in-lb. Final preload on replacement balls should be 2-3 in-lbs.

Remove the valve assembly from the worm and the rack piston from the vise.

13. Insert Tool T65P-3D517-A into the plug end of the rack and piston to contact the worm shaft (Fig. 29). Apply pressure on the tool while rotating the worm shaft out of the piston and rack. Leave the tool in place until the piston is installed in the housing.

DESCRIPTION

STEERING GEAR

The Power Steering Gear used in W-Series vehicles (Fig. 1) is a semi-integral hydraulic steering gear. It incorporates a hydraulic control valve on a single stud cam and lever mechanical steering gear. Steering effort applied to the steering wheel actuates the valve which directs hydraulic fluid from the power steering pump to the power cylinder.

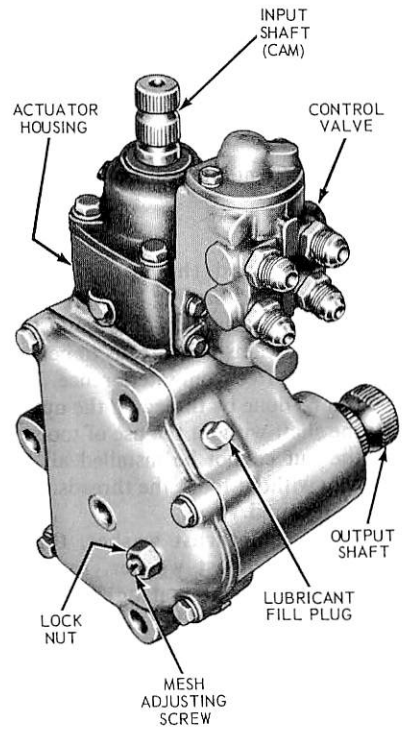

FIG. 1 Model HPS-70 Power Steering Gear

ADJUSTMENTS

MESH LOAD

The groove of the cam is cut shallower and narrower in the mid-position range of stud travel. This is to provide close adjustment in the straight ahead position. This adjustment must be made through the mid-position to the high spot. **Do not adjust the mesh adjustment in any position except the straight ahead position. Backlash is normal when the steering gear cam is in the end position, (wheels turned to one side).**

1. Disconnect the drag link and power steering cylinder from the Pitman arm and the universal joint from the gear input shaft.
2. Loosen the adjusting screw lock nut. Then, turn the adjusting screw (Fig. 1) clockwise until a 15 in-lb torque is required to turn the steering gear through the mid-position.
3. Back out (counterclockwise) the adjusting screw 1/8 turn.
4. Tighten the adjusting screw lock nut to 15-20 ft-lb torque to lock the adjustment. Be sure the adjusting screw does not turn when tightening the lock nut.
5. Turn the gear through its full travel with the engine off to check the adjustment. The torque at the input shaft should be 2 to 8 in-lb for the full travel (stop to stop).
6. Connect the drag link and power steering cylinder to the Pitman arm and the universal joint to the steering gear input shaft.

THRUST BEARING

1. With the steering linkage disconnected, turn the steering gear off the center position to free the stud roller bearing from the cam groove.
2. Remove the clamp bolt and nut from the input shaft (cam) U-joint and separate the joint from the input shaft.
3. Remove four upper cover attaching screws and remove the upper cover from the gear. Care must be used to remove burrs and paint from the input shaft to avoid cutting the seal.
4. Install the upper cover attaching screws in the actuator housing with 3/8 inch thick spacers under the screw heads. This will hold the actuator and cam assembly in the gear during the adjustment.
5. Straighten the lock washer prong and remove the adjusting nut, lock washer, and the upper thrust washers and bearing.
6. Check the condition of the adjusting nut and camshaft threads to be sure they are free from interference. This can be done by threading the nut on the shaft without the use of tools. If the nut cannot be installed all the way without tools, the threads must be repaired.
7. Position a thrust washer, thrust bearing, thrust washer, tongued washer (with internal lug) and a new lock washer on the shaft (Fig. 2). Then, install the adjusting nut. **Do not bend the lock washer prongs at this time.**
8. Torque the adjusting nut to 10 ft-lbs. Then, back the nut off 10 degrees to 20 degrees (approximately 1 1/2 widths of the tongued washer lug). **The centering washers must be properly centered on the actuator during this adjustment.** Bend the lock washer lug that is nearest in alignment with a notch in the adjusting nut so that the lug is tight against the notch root.
9. Remove the 3/8 inch spacers and install the upper cover.
10. Position the U-joint on the steering gear input shaft and install the clamp bolt and nut.

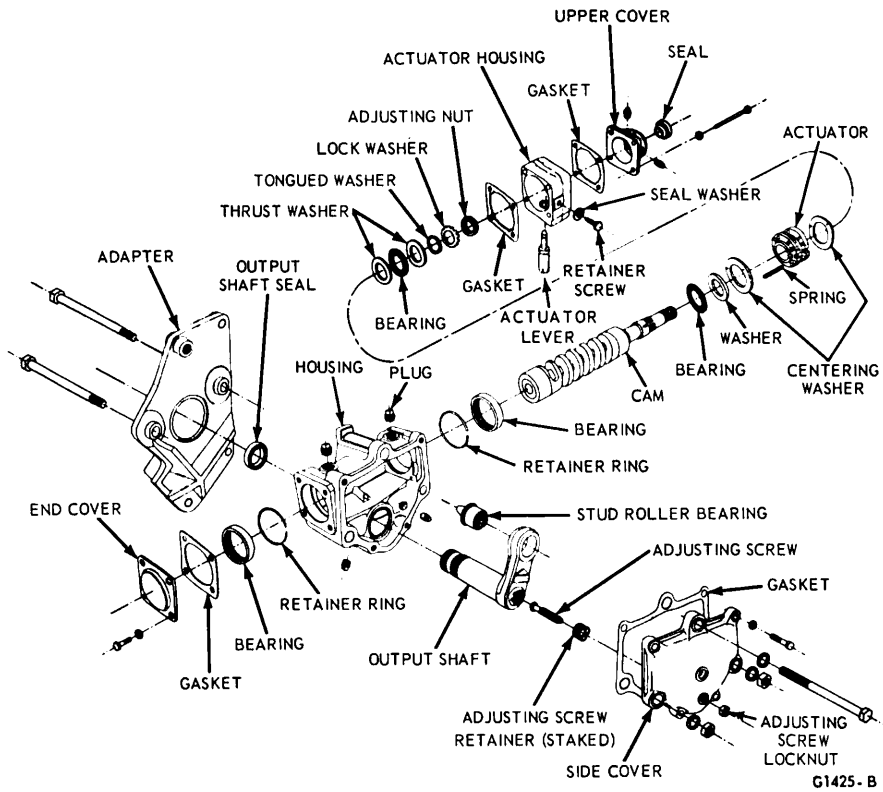

FIG. 2 Semi-Integral Power Steering Gear — Disassembled

STUD ROLLER BEARING

The output shaft must be removed from the steering gear to adjust the stud roller bearing.

The operation of a properly adjusted roller bearing may feel rough when turned by hand. However, under a steering load it will be smooth and will give normal service life.

1. Wash the bearings in solvent, dry, and lubricate with gear lubricant. If a roller is lost or damaged, a new set should be installed. **Do not make partial replacement of the rollers.**
2. Assemble the bearing and install a new locking washer.
3. Install the adjusting nut and tighten as required to obtain a 1 to 4 in-lb preload on the bearing.
4. Rotate the stud several complete turns in each direction. Then check the rotational torque of the bearing and re-adjust to 1-4 in-lb if necessary.
5. Lock the adjustment with two lock washer prongs against the side of the nut. **If the lock washer is not replaced, the used prongs should be removed from the washer.**
6. Lubricate the bearing with steering gear lubricant.

REMOVAL AND INSTALLATION

STEERING GEAR

Removal

1. Unlatch the cab and raise it to the full tilt position.
2. Remove the grille from the front of the cab.
3. Mark the power steering hose locations and disconnect the hoses from the steering gear control valve. Plug the hoses and the valve fittings with suitable plugs and caps.
4. Remove the cotter pin and nut attaching the hydraulic cylinder to the Pitman arm. Remove the cylinder stud from the Pitman arm and position the cylinder to one side.
5. Remove the cotter pin and nut attaching the drag link to the Pitman arm. Remove the drag link stud from the Pitman arm and position the drag link out of the way.
6. Remove the steering shaft U-joint nut, bolt and flat washer and separate the joint from the steering gear input shaft.
7. Remove the three gear and bracket-to-frame bracket attaching bolts four nuts, flat washers and cotter pins and remove the gear and bracket from the vehicle.
8. Position the gear bracket in a vise and remove the Pitman arm from the output shaft.
9. Remove the three bolts and two nuts attaching the gear to the bracket and separate the gear from the bracket.

Installation

1. Position the gear to the bracket and install the bolts and nuts. Torque the bolt and nuts to specification.
2. Install the Pitman arm on the output shaft as shown in Fig. 3, and torque the clamp bolt to specification. Install cotter pin.
3. Position the steering gear and bracket to the frame bracket and install the bolts, hardened flat washers and nuts. Torque the bolts and nuts to specification and install the cotter pins.
4. Connect the drag link to the Pitman arm. Torque the nut to specification and install the cotter pin.
5. Connect the hydraulic cylinder to the Pitman arm. Torque the nut to specification and install the cotter pin.
6. With the wheels and steering wheel in the straight ahead position, place the steering shaft U-joint on the steering gear input shaft. Install a new bolt, nut and the hardened flat washer retaining the steering shaft to the steering gear and torque the nut to 28-35 ft-lbs. **Make certain the bolt is engaged in the slot of the steering gear input shaft.**

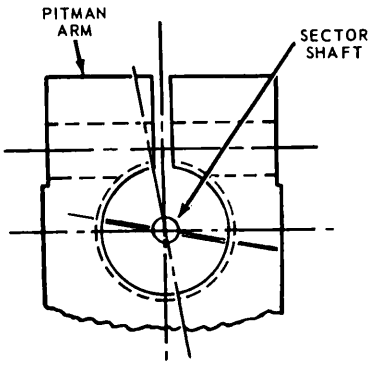

FIG. 3 Pitman Arm Installation — W-Series

7. Connect the hoses to their respective fittings on the control valve.
8. Fill the reservoir with fluid and lower the cab. Start the engine and turn the steering wheel from side to side three or four times to bleed air from the system.
9. Install the grille on the front of the cab.

DISASSEMBLY AND ASSEMBLY

STEERING GEAR

Prior to disassembly, drain the gear assembly and thoroughly remove all outside dirt around the fittings before disconnecting the hoses. The port holes should be plugged immediately after disconnecting the hoses and before removing the gear from the vehicle. Finish cleaning and drying the gear before placing it on the work bench.

During disassembly of any component parts, make sure a clean work bench or table is used. All internal parts should be cleaned in clear, clean solvent and blown dry with clean air. Avoid wiping valve parts with a cloth as lint may actually cause binding or sticking of closely fitted parts. Never steam clean hydraulic steering assemblies and do not force or abuse closely fitted parts.

Disassembly

1. Remove the drain plugs and drain all lubricant from the gear housing.
2. Remove the side cover attaching bolts.
3. Remove the lock nut from the adjusting screw in the side cover.
4. Turn the adjusting screw to remove the cover from the screw and remove the gasket from the housing.
5. Remove any dirt, rust or burrs from the output shaft and pull the output shaft from the housing.
6. Remove four valve body attaching bolts and remove the valve body from the actuator housing.
7. Remove the actuator lever (Fig. 2) from the actuator housing.
8. Remove four bolts attaching the upper cover and actuator housing (Fig. 2) to the steering gear housing.
9. Remove the cam, actuator housing, and upper cover as an assembly from the steering gear housing.
10. Remove the upper cover from the cam and actuator housing.
11. Remove the actuator retaining screw from the actuator housing and remove the housing from the cam.
12. Remove four end cover attaching bolts and remove the cover and gasket from the housing.
13. If necessary, remove the two cam bearing retaining rings from the housing.
14. If necessary, press the cam bearings from the housing with a socket.
15. If necessary, remove the output shaft seal from the housing.
16. Place the cam in a soft jaw vise.
17. If necessary, straighten the tab on the lock washer and remove the adjusting nut, lock washer, and tongued washer.

18. If necessary, lift the thrust washers, bearings, and actuator from the cam. Be careful not to lose the springs or their locations in the actuator.
19. If necessary, remove the nut and tab washer from the output shaft follower and remove the stud, roller bearings, and race.

Assembly

1. Install the two cam bearing retainer rings in the steering gear housing.
2. Press the cam bearings in the housing with a socket of slightly smaller diameter than the cam bore. (Press only against the numbered end of the bearing to prevent crushing the end of the bearing.) Press the bearing lightly against the retaining ring.
3. Install the thrust bearing, washer, and centering washer on the cam (Fig. 2).
4. Install the actuator and springs, centering washer, thrust washer, thrust bearing, thrust washer, tongue washer (with internal lug), new lock washer, and adjusting nut on the cam (Fig. 2).
5. Place the cam in a soft jaw vise.
6. Tighten the adjusting nut to 10 ft-lb torque. Then, back the nut off 10 degrees to 20 degrees (approximately 1 1/2 widths of the tongued washer lug). Bend the washer lug that is nearest in alignment with a notch in the adjusting nut so that the lug is tight against the notchroot. **The centering washers must be centered on the actuator during this adjustment.**
7. Install the cam and actuator into the gear housing from the end shown in Fig. 2.
8. Position the gasket and actuator housing over the actuator and install the actuator retainer screw and lock washer. Bend the washer against the retainer screw to lock the screw in place.
9. Install a new seal in the upper cover.
10. Position the upper cover and gasket to the actuator housing and install the four attaching bolts. Torque the bolts to specification.
11. Position the gasket and lower end cover to the housing and install the four attaching bolts. Torque the bolts to specification.
12. Install the stud, roller bearings, and cone in the output shaft and install the attaching nut and washer. Tighten the nut as required to obtain a 1-4 in-lb rotational preload.
13. Rotate the stud several complete turns in each direction. Then, check the rotational torque of the bearing and readjust to 1-4 in-lb preload if necessary.
14. Lock the adjustment with two lock washer prongs against the side of the nut. **If the lock washer was not replaced, the used prongs must be removed from the washer to prevent the prongs from being used again.**
15. Install a new output shaft seal in the housing.
16. Check the end play between the adjusting screw and the output shaft. If the end play of the assembled output shaft adjusting screw exceeds .005, replace it with a new threaded adjusting screw retainer. Stake the retainer into any 2 of 4 slots into the slots on the end of the output shaft using a chisel point punch. Adjust to no perceptible end play to .002 loose.
17. Position the side cover gasket to the housing.
18. Position the side cover to the output shaft adjusting screw and thread the screw through the housing cover until the cover is against the housing. Install the lock nut on the adjusting screw.
19. Install the housing cover attaching bolts and torque to specification.
20. Adjust the side cover adjusting screw as required to provide a 15 in-lb torque at the input shaft as the gear is moved through the center position.
21. Back the adjusting screw out 1/8 turn and tighten the adjusting screw lock nut to 15-20 ft-lbs torque. **Be sure the adjusting screw does not turn when tightening the lock nut.** The torque at the input shaft should be 2 to 8 in-lbs for the full travel (stop to stop) of the gear. This torque includes lubricated seal friction.
22. Fill the actuator with specified lubricant through the lever opening until it is visible in the pipe plug hole (approximately 2 1/4 ounces).
23. Fill the end of the valve with lubricant (approximately 1/2 ounce) through the lever opening.
24. Insert the actuator lever into the actuator housing (Fig. 2).
25. Position the valve body and gasket to the actuator housing and install the attaching screws. Torque the screws to specification.
26. Install three plugs in the gear housing.
27. Fill the housing with lubricant and install the remaining plug.

VALVE HOUSING

Disassembly

1. Remove the retainer, cover plate, and O-ring (Fig. 4) from the valve

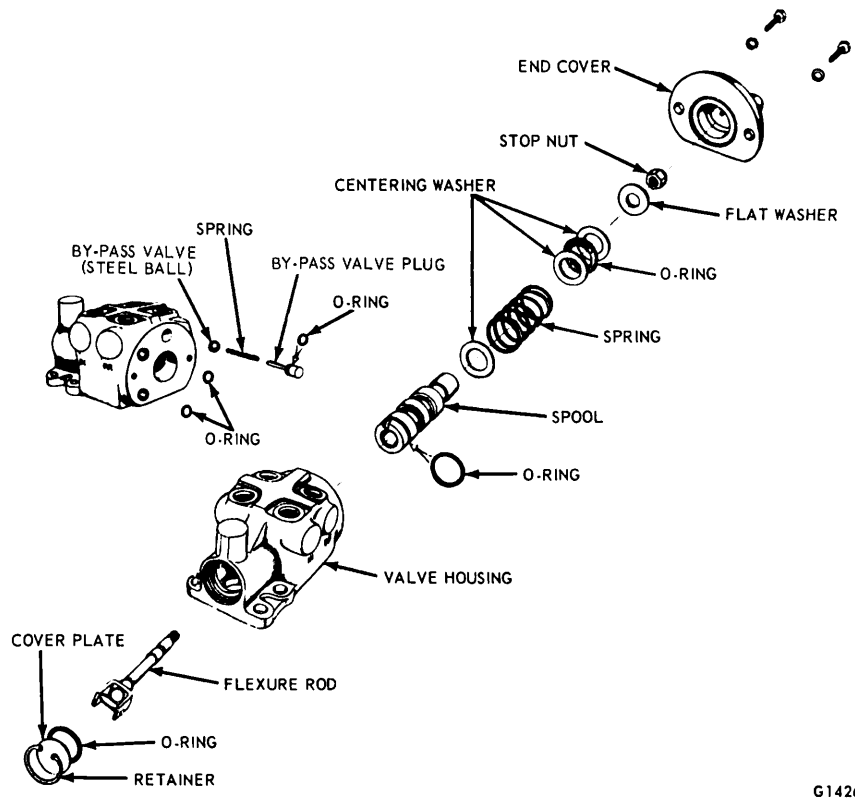

FIG. 4 Valve Housing Disassembled

housing.
2. Remove the end cover and O-ring from the other end of the housing.
3. Remove the lock nut and washer from the flexure rod and pull the rod out of the valve housing.
4. Push the spool out of the housing in the same direction as the flexure rod was removed.
5. Remove the O-ring from the spool.
6. Remove the by-pass valve plug, spring and steel ball from the valve housing. Remove the O-ring from the plug.
7. Remove the centering washers, spring and seal from the valve housing.

Assembly

All parts must be clean and should be lubricated with light oil before assembly.

1. Install the O-ring on the by-pass valve plug (Fig. 4).
2. Install the by-pass valve (steel ball), spring, and by-pass valve in the valve housing.
3. Install the O-ring on the valve spool.
4. Install the spool in the valve housing with a twisting motion after lubricating the O-ring. **The O-ring end of the spool must be toward the actuator lever opening end of the housing (Fig. 4).**
5. Insert the flexure rod through the valve spool.
6. Install the centering washer, spring, centering washer, O-ring, centering washer, flat washer and new stop nut on the flexure rod. **The stop nuts should never be re-used.** Torque the stop nut to 125 to 150 in-lbs. Check to be sure the valve spool can be moved in the valve housing.
7. Position the two O-rings in the end of the valve housing and install the end cover.
8. Install the O-ring, cover plate, and retainer in the other end of the housing.

DESCRIPTION

STEERING GEAR

The Ross Hydrapower HF-54 and HF-64 gears, used on all F-B-LN-L-LT-LNT-LTS-500 through 9000 Series vehicles are fully integral steering gears incorporating a hydraulic control valve, a power cylinder, and a mechanical means of steering control (Figs. 1 and 2).

The power of the cylinder is transmitted to the steering gear output (sector shaft) shaft by means of gear teeth on the rack piston mating with the sector gear. The flow of fluid from the engine-driven pump is directed to the power cylinder via the control valve. The valve is located concentric with the input shaft.

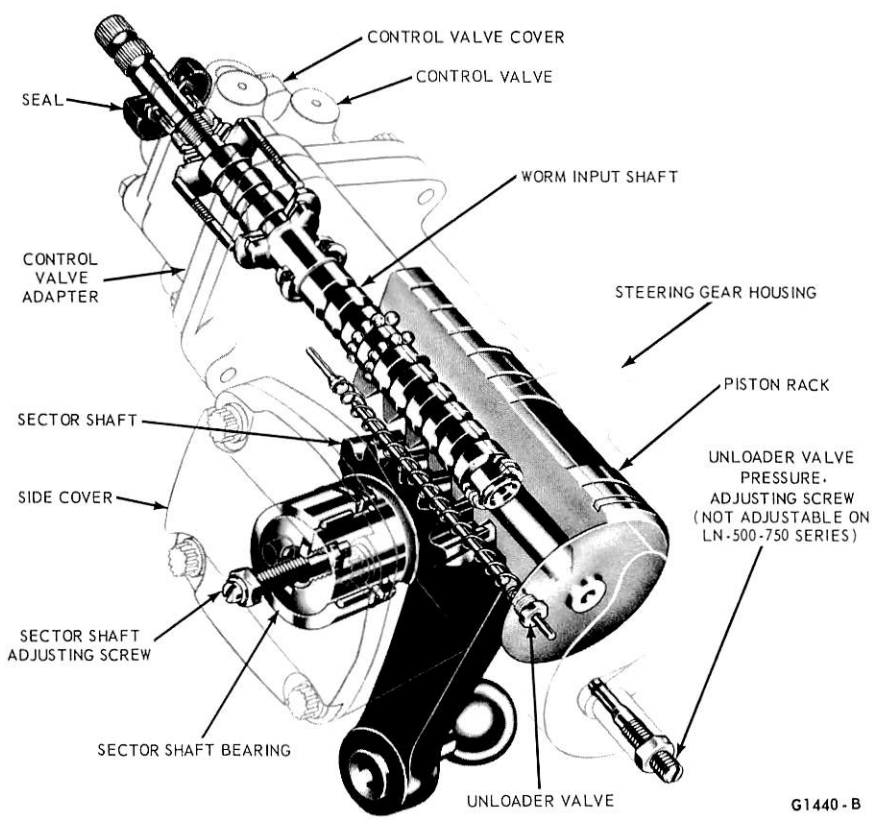

FIG. 1 Ross Integral Power Steering Gear — Model HF-54

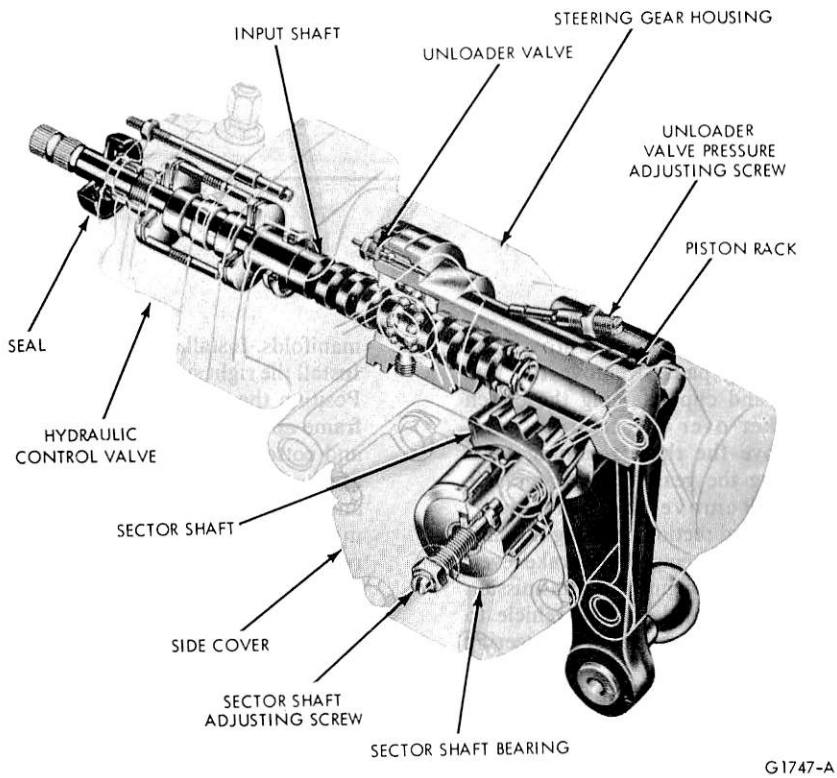

FIG. 2 Ross Integral Power Steering Gear — Model HF-64

ADJUSTMENTS

UNLOADER VALVE

This unloader valve adjustment is for **right turn only** on HF-54 Model gears and for **both turns** on HF-64 Model gears. Prior to performing the following procedure, obtain the vehicle's straight ahead position by driving the vehicle with hands off the steering wheel thus allowing the unit to find its own center. Now mark the steering column to steering wheel with chalk or masking tape.

1. Check the front wheel turning angles and adjust as required with the wheels off the ground (see the Specifications Section of Part 14-01).
2. Position the wheels straight ahead and lower the vehicle.
3. RIGHT TURN — HF-54 OR HF-64 GEARS: With the engine at idle, the vehicle standing still and the fluid at normal operating temperature, rotate the steering wheel to the right the prescribed number of turns (Specifications Section of this Part). Hold in this position (but not longer than 15 seconds).
4. Loosen the lock nut and turn the unloader valve pressure adjusting screw until an audible hiss is heard. Tighten the lock nut to specification.
5. Return the wheel to a straight ahead position while the vehicle is moving. With the vehicle standing still, again rotate the steering wheel the prescribed turns; then, check for the audible hiss. Readjust if necessary as in Step 4 and check once more as in this step.

It is important to remember that the HF-64 gear has a Pitman arm stop for the right turn cast on the gear housing. The Pitman arm **must not** contact this stop prior to contacting the unloader valve. When the hiss is heard during the adjustment, the clearance between the Pitman arm and the cast stop should be 1/16 to 1/8 inch minimum.

6. LEFT TURN — HF-64 GEAR ONLY: Repeat Steps 3, 4 and 5 while rotating the steering wheel to the left the prescribed number of turns (Specifications Section of this Part).

SECTOR SHAFT

1. Disconnect the drag link from the Pitman arm.
2. Center the steering wheel. Grasp the Pitman arm and check it for free movement (lash) between the sector shaft and the rack piston.
3. If free movement is noted (lash), remove the steering gear from the vehicle.
4. Loosen the sector shaft adjustment screw lock nut on the side cover.
5. After rotating the input shaft through its full travel for a minimum of five cycles, adjust the sector shaft adjusting screw to provide 15-20 in-lb torque as the input shaft is rotated 90 degrees each side of center.
6. Back out the adjusting screw one turn and note the torque required to move the input shaft 90 degrees each side of the center position. Move the adjusting screw in to provide an increase in torque of 2-4 in-lb at a point within 45 degrees each side of center after the adjusting screw jam nut is first tightened snug. Now torque to a final 20-25 ft-lb. The

input torque of the completely assembled gear, minus hydraulic oil, should not exceed 15 in-lb for the full travel of the output shaft.
7. Install the steering gear in the vehicle.
8. Connect the drag link to the Pitman arm.
9. Connect the pump lines and refill the system with the specified fluid.

REMOVAL AND INSTALLATION

STEERING GEAR

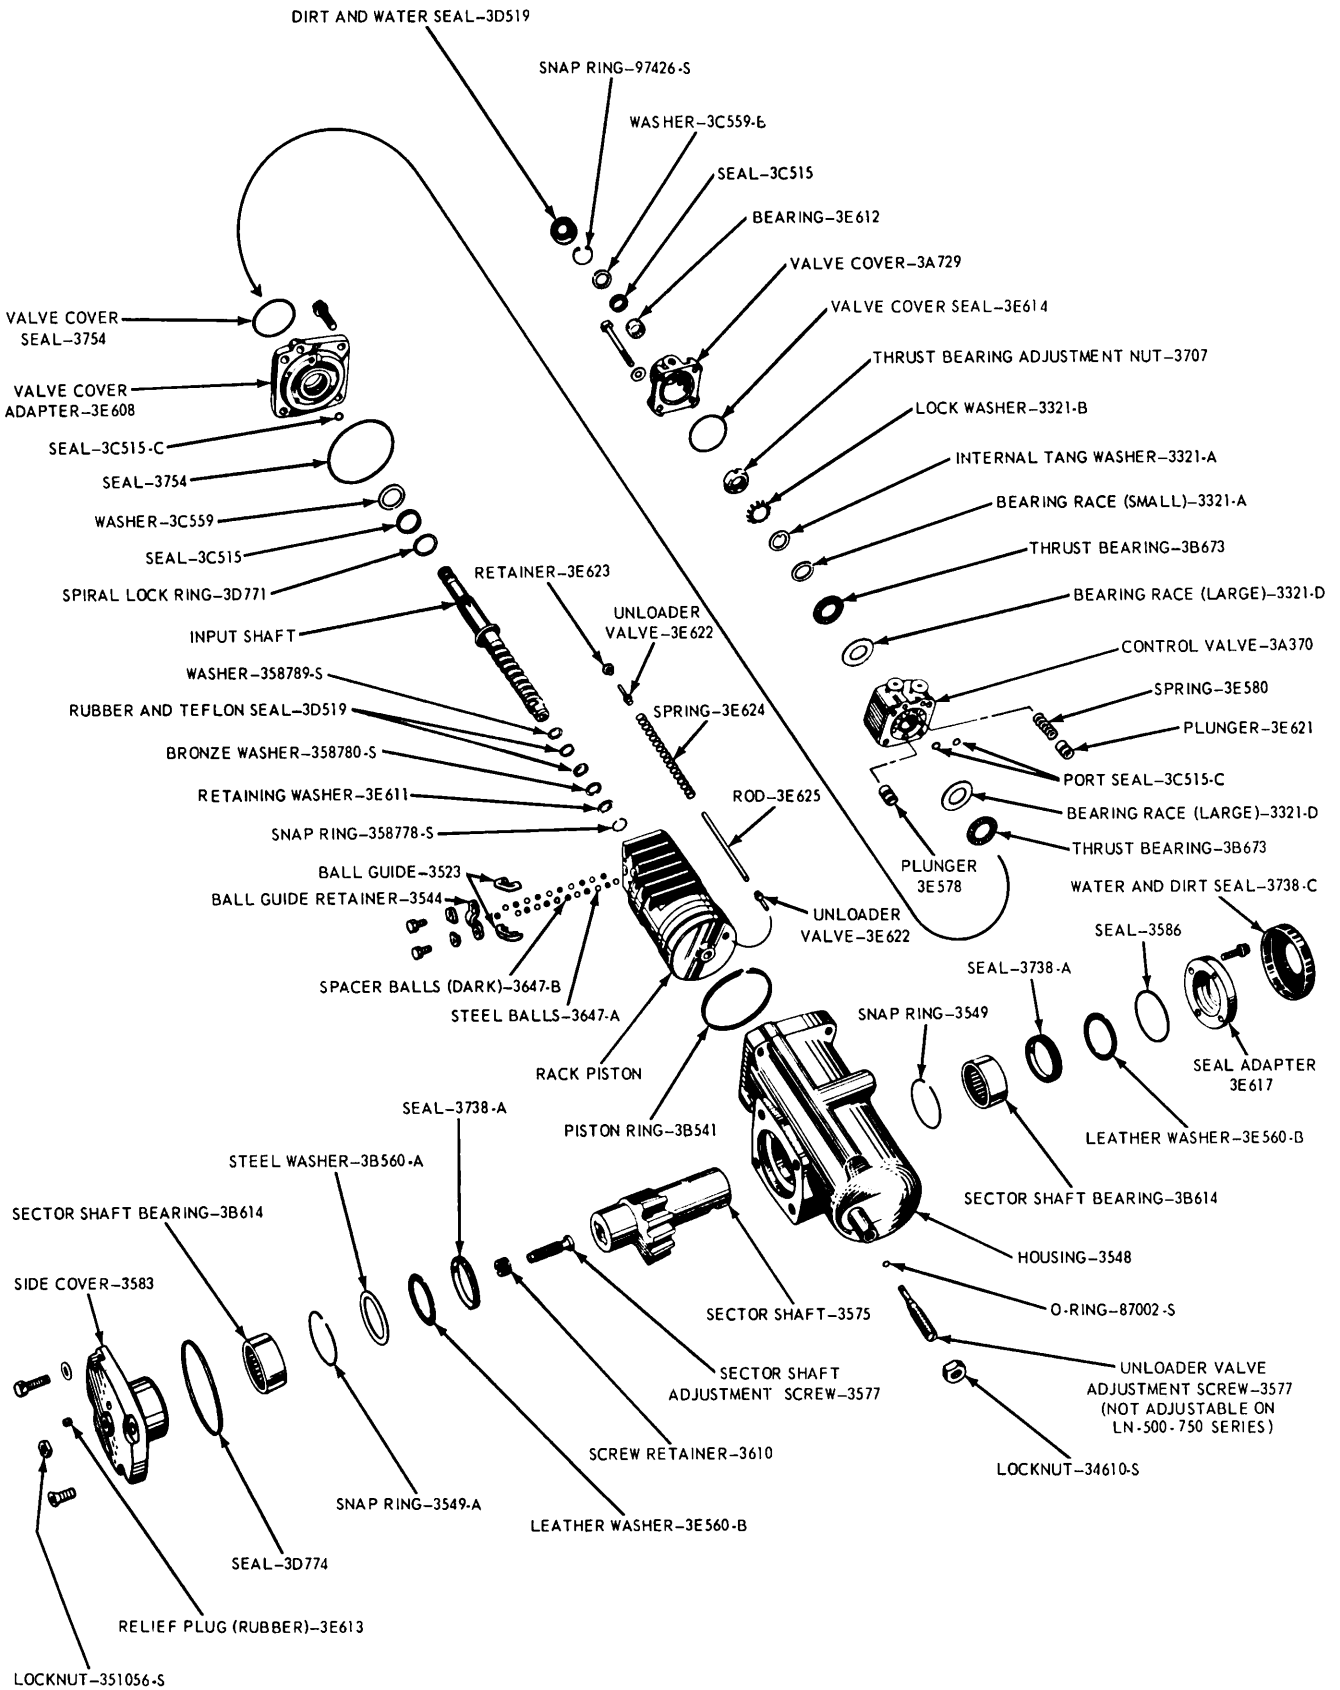
Removal
1. Position a drain pan under the steering gear.
2. Disconnect the power steering pressure line at the steering gear.
3. Disconnect the power steering return line at the steering gear.
4. Disconnect the turning hoses if so equipped.
5. Remove the bolt and nut (or castellated nut and cotter pin on some series) retaining the Pitman arm to the sector shaft and remove the Pitman arm from the sector shaft using Tool T64P-3590-F.
6. Remove the bolt, bolt and nut or castellated nut and cotter pin retaining the U-joint to the steering gear input shaft and slide the joint up off the input shaft.
7. On F-600-700-750, B-600-700-750 units with standard transmission only, loosen the front engine mount retaining nut and bolt. Remove the left and right side inlet pipe retaining bolts and the exhaust shield. Remove the clutch spring bracket retaining bolt and nut and remove the bracket from under the left side inlet pipe. Remove the two transmission mount retaining bolts and nuts. Position a floor jack under the transmission, raise the transmission and remove the mounting pads. Remove the two bolts and clip retaining the clutch bracket over the steering gear. Remove the three retaining bolts holding the gear to the frame side rail. Remove the portion of floorboard section covering the shift lever and the emergency brake lever. Position the engine and transmission to the right side of the vehicle to allow for the removal of the steering gear.
8. On other units, remove the bolts and nuts retaining the steering gear or the steering gear bracket to the frame side rail and remove the steering gear.

Installation
1. Position the gear (or gear and bracket) to the side rail. Install the bolts and nuts (and lock straps on some series) and torque to specification. Install the cotter pins (advance to next castellation if necessary after torquing to specification).
2. Position the intermediate shaft U-joint to the steering gear input shaft and install the bolt, bolt and nut or castellated nut and cotter pin to retain. Torque to specification.
3. On F-600-700-750, B-600-700-750 units only, position the exhaust inlet pipe to the right and left exhaust manifolds. Install the retaining nuts. Install the right side manifold shield. Position the clutch bracket to the frame and install the retaining bolts and cotter pin. Position the Pitman arm to the gear and install the bolt and retaining nut. Position the rear mounting pads and install the retaining bolts and nuts. After lowering and removing the jack, torque the mounting pad nuts to specification. Position the clutch spring bracket to the frame and install the retaining bolt, washer and nut. Connect the spring. Tighten the front engine mount retaining nut and bolt. Position the floor board over the gear shaft and emergency brake levers and install the retaining screws.
4. On other units, position the Pitman arm to the steering gear sector shaft, install the bolt and nut (castellated nut and cotter pin on some series) and torque to specification.
5. Connect the power steering return and pressure lines to the steering gear.
6. Connect the turning hoses if so equipped.
7. Fill the power steering system to the correct level with specified fluid.
8. Start the engine, cycle the system and check for fluid leaks.
9. Remove the drain pan.

DISASSEMBLY AND ASSEMBLY

STEERING GEAR

Disassembly
1. Rotate the input shaft (Figs. 3 and 4) so the index mark on the end of the sector shaft is perpendicular to the center-line of the gear (straight-ahead position).
2. Remove the four (six on Model HF-64) side cover attaching screws and washers.
3. Tap lightly on the end of the sector shaft with a soft hammer to disengage the side cover seal and allow the housing to drain.
4. Remove all nicks, burrs, rust and paint before removing the shaft. Lift the side cover and sector shaft from the housing as an assembly.
5. Remove the sector shaft seal adapter attaching screws and remove the adapter from the housing.
6. Remove the four screws that attach the control valve adapter to the housing.
7. Remove the control valve and rack piston from the housing as an assembly.
8. Remove the sector shaft adjustment screw lock nut (Figs. 3 and 4). Turn the adjustment clockwise until free of the side cover.
9. Remove the unloader valve retainer,



G1455-C

FIG. 3 Steering Gear Disassembled — Model HF-54

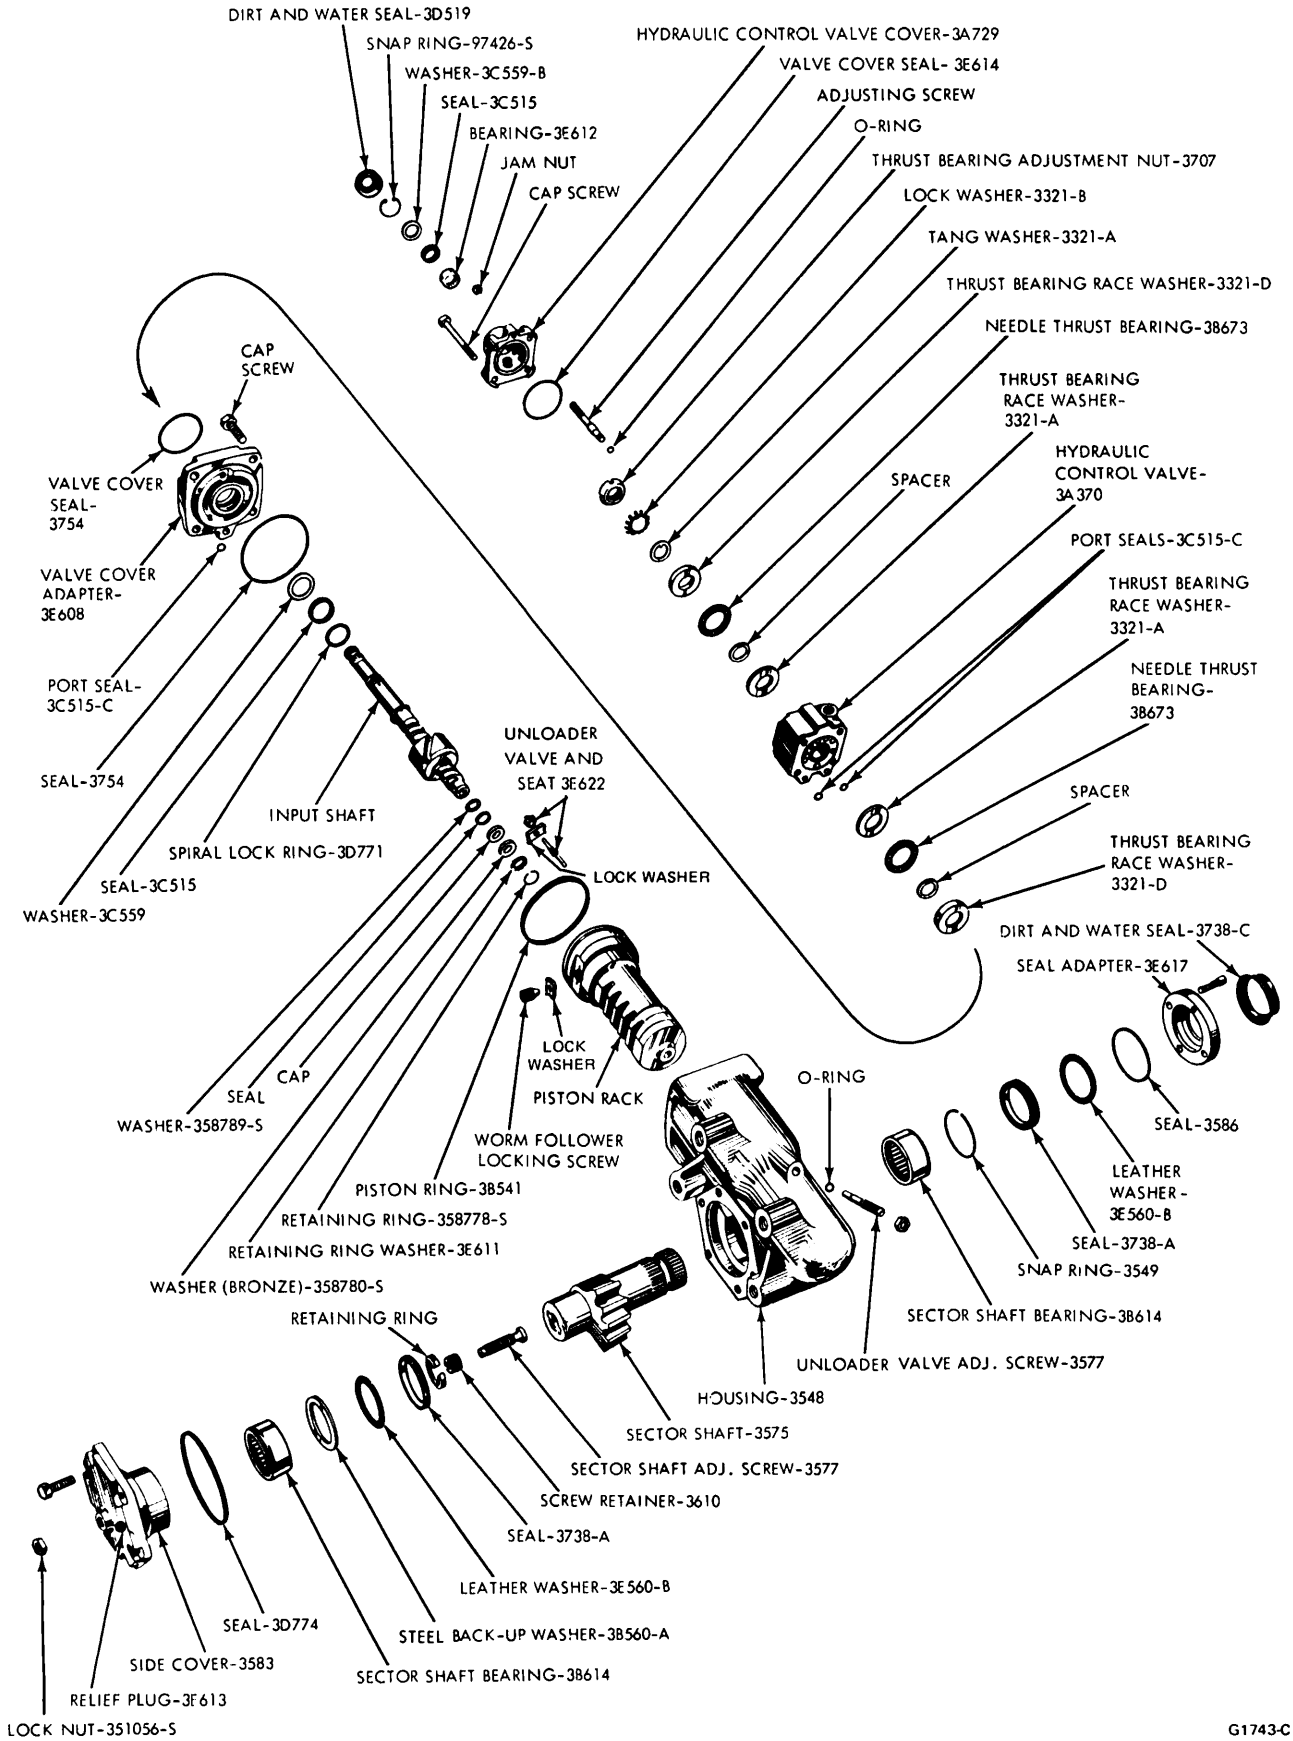


FIG. 4 Steering Gear Disassembled — Model HF-64

unloader valves, rod and the spring from the rack piston.

10. If all parts appear undamaged, do not disassemble the rack piston assembly. If there is evidence of damage, place the rack piston on a clean surface with the ball return guides facing upward. Remove the two ball return guide retainer attaching screws, lock washers, guide retainer, guide and balls. It may be necessary to tilt the rack piston over a clean pan and oscillate the worm shaft to empty the rack of all the balls. Lift the worm shaft from the rack after all the balls have been removed.
11. Carefully hold the input shaft in a vise equipped with soft jaws. Remove the snap ring, washer, bronze washer, cup, seal and washer (Fig. 5). It may be necessary to cut the teflon cup off the shaft.
12. Remove the valve cover dirt and water seal (Figs. 3 and 4).
13. Remove the four valve cover attaching screws. Lift the cover from the control valve.
14. Unstake the thrust bearing adjustment nut lock washer and remove the adjustment nut.
15. Remove the lock washer, internal tang washer, bearing race (small), thrust bearing and the large bearing race.
16. Lift the control valve and the control valve adapter from the input shaft.
17. Remove spiral lock ring, seal and washer from the counterbore of the valve cover adapter. Discard the washer and seal.
18. Do not disassemble the valve unless absolutely necessary. The valve is the control center of the hydraulic system. The major parts, which are the body and spool, are machined to very close tolerances and with precision machined edges. The spool and valve body are selectively fitted at the factory, and therefore these two parts are not separately replaceable. If either is damaged or excessively worn, the complete valve assembly should be replaced. Good performance of power steering is not assured if a mismatched valve spool and body are used. Care should be exercised in the handling of these parts to prevent damage. Sealing edges of the valve bore and the spool should not be broken.

This will result in excessive leakage and reduced hydraulic power.

If valve parts should drop out during gear disassembly, reassemble the valve as follows:

a. Clean all parts with a clean petroleum base solvent and blow dry with clean, dry air.
b. Insert the valve spool in the control valve making certain that the machined identification groove in the ID of one end of the spool is toward the **gear housing (Part No. 3548** on Figs. 3 and 4).
c. There are 7 sets of plungers, each set having one reaction spring. Insert the 6 **solid** centering plunger sets first along with one spring per set (Check Valve Plunger Assembly on Fig. 6) should be inserted in the valve body with the small hole on each plunger facing outboard.

CLEANING AND INSPECTION

1. All parts should be cleaned in a clean petroleum base solvent and blown dry with clean dry air. Avoid wiping parts with a cloth, since lint may cause binding and sticking of closely fitted components.
2. Inspect the worm grooves in the rack piston and on the input shaft for wear scores. Inspect the OD of the rack piston and the ring or teeth for wear or scores. On the HF-64 gear, the ball nut and input shaft are serviced as a matched assembly. Therefore, both must be replaced if either are worn or damaged. The rack piston is not matched.
3. Inspect the inside ends of the ball return guides for wear or damage.
4. Inspect the housing bore for wear or scores or being cracked and replace as required.
5. Inspect the sector shaft teeth for wear or the bearing surfaces for wear or scores.
6. Replace the sector shaft bearings if worn or damaged. **Note the sector shaft bearing in the side cover is replaced as part of the side cover assembly.**
7. Replace all seals at time of disassembly.

Assembly

1. Lubricate all rubber parts prior to assembly.
2. If the sector shaft bearing was removed from the steering gear housing, install the snap ring in the outboard side of the housing (HF-54 gear only) (Fig. 3).
3. Place the steering gear housing in a press with the side cover area on a wood block to prevent damage to the machined area.
4. Position the bearing on the housing with the numbered end facing up. Carefully press the bearing into the housing until the outer surface is flush. Use a tool that pilots in the ID of the bearing and contacts the bearing end surface.
5. Coat the unloader valve pressure adjusting screw O-ring liberally with clean grease or oil. Carefully slide it into the groove on the non-threaded end of the adjusting screw.
6. Thread the adjusting screw into the lower end of the housing leaving 7/8 inch of the screw exposed. Install the lock nut on the adjusting screw and tighten it securely.
7. Carefully secure the input shaft in a vise equipped with soft jaws to permit access to both ends of the shaft.
8. On HF-54 gears, slide the bearing race (large) thrust bearing, control valve (with cylinder ports toward the shoulder), bearing race (small), internal tang washer, lock washer and thrust bearing adjustment nut (Fig. 3).

On HF-64 gears, slide the thrust bearing race washer, spacer, control valve (with cylinder ports toward the shoulder) needle thrust bearing, thrust bearing race washer, tang washer, lock washer and thrust bearing adjustment nut (Fig. 4).

9. Tighten the adjustment nut to 20 ft-lbs, then back it off 1/2-1 lock washer tangs. Bend one tang of the lock washer into the slot provided on the adjustment nut. When adjusted in this manner, the control valve should rotate freely on the shaft with a torque of 2-3 1/2 in-lbs and have no perceptible end play.
10. Assemble a new washer, seal and the spiral lock ring in the counterbore of the valve cover adapter. Make sure that the lip of seal is facing toward the spiral lock ring (Fig. 5).
11. Coat a new valve cover seal and two new cylinder port seals with grease to retain them in place. Position the seals in the recesses provided in the control valve cover adapter (Figs. 3 and 4) on the surface adjacent to the control valve.
12. Reposition the input shaft in the vise securing the serrated end.
13. Slip the adapter over the worm groove end of the input shaft. Align the cylinder port seals with the ports in the control valve. Install one of the attaching bolts finger tight to facilitate assembly.
14. Assemble the washer (steel), a new rubber seal, new teflon cup with the lip toward the seal, bronze washer and retaining washer. Compress the washer and seal, then install the snap ring on the end of the input shaft. Make sure that the snap ring

is fully seated in the groove and the recessed area of the retaining washer.

15. Secure the rack piston in a soft-jawed vise with the ball guide holes facing upward.
16. Carefully expand the piston ring and install it in the piston groove.
17. On HF-54 gears, clean the threads on both unloader valves and place the valves, the spring and rod in the rack piston as shown in Fig. 5. Apply a drop of Lock-tite Type A to the threads of the retainer. Install and torque the retainer to specification.

On HF-64 gears, clean the threads on the unloader valve and insert it into the rack piston. Clean the threads on the seat and apply Lock-tite. Assemble the seat with a new lock washer and tighten to specification. Bend the lock washer against one flat of a hex on the seat.

18. Coat the input shaft seal at the end of worm with grease and place it in the rack piston bore.
19. Assemble sixteen balls while rotating the input shaft counterclockwise. The black spacer balls and the polished steel balls must be installed alternately. Coat the ball return guides with grease to retain the balls, then install the six remaining balls in the guides making sure that the balls in the guide alternate with the last balls installed in the rack piston. **If a ball is lost, no more than three black spacer balls may be used for replacement.** Secure the guide retaining clip to the rack piston with two screws and washers. Torque the screws to specification and bend the tab of the locking washer against the flat.
20. Grip the serrated end of the sector shaft in a soft-jawed vise.
21. Coat the head of the sector shaft adjusting screw with C2AZ-19585-A grease. Position the head of adjusting screw into the slot in the end of sector shaft.
22. Install a new sector shaft adjustment screw retainer in the end of shaft. Tighten the retainer to permit free rotation of screw without perceptible end play. Stake the retainer in the two slots provided and recheck the rotation effort.
23. If the pressure relief plug has been removed or ruptured, press a new one into the side cover until it is flush with the surface.
24. Assemble the snap ring (HF-64 gear only), steel washer (with taper toward the snap ring), leather washer and the two piece seal into the side cover. The seal has Oil Side molded into one side and must be visible after installation.
25. Coat the end of sector shaft with lubricant. Rotate the sector shaft adjusting screw counterclockwise to thread it into the side cover. Rotate the screw until a firm stop is reached. On HF-54 gears, make sure that the shaft seal has not falled out of position.
26. Place the outer seal (Figs. 3 and 4) in the seal adapter. Then install the leather washer and inner seal making sure that the side having the mold **Oil Side** is visible after installation.
27. If the input shaft needle bearing has been removed from the control valve cover it must be installed with a tool that will pilot in the bearing and have clearance in the cover bore. The bearing must be pressed from the part number end, and to a depth of 1 1/8 inches from the face of the valve cover. After installation of the bearing, make sure that all rollers rotate freely.
28. Install the seal on the control valve cover with the lip facing toward the needle bearing. Coat the washer with grease and install it on the cover. Install the snap ring to secure the seal and washer.
29. Pack the new dirt and water seal with C2AZ-19585-A grease and install it on the control valve cover (Figs. 3 and 4).
30. Secure the steering gear housing in a vise equipped with soft-jaws.
31. Lubricate the steering gear housing bore. Start the rack piston into the bore, then compress the ring and move the piston into position so that the teeth are visible through the side cover opening. Install the four adapter-to-housing attaching bolts. Remove the one bolt that was previously installed.
32. Lubricate a new valve cover seal (Fig. 2) with grease and position it in the recess of the valve cover.
33. Slide the valve cover onto the input shaft and install the four cover-to-control valve attaching bolts.
34. Rotate the input shaft as required to align the center tooth of the rack piston (marked tooth) with the side cover opening.
35. Lubricate a new side cover O-ring and position it on the side cover.
36. Position the sector shaft and side cover to the steering gear housing making sure that the center tooth (marked tooth) engages the center space (marked space).
37. Install the four side cover attaching bolts and lock washers. Torque the bolts to specification.
38. Adjust sector shaft adjustment screw as outlined in the Sector Shaft Adjustment, Adjustments section of this Part.
39. Cover the sector shaft serrations with a layer of scotch tape to prevent damage to the seal in the adapter.
40. Position the adapter over the sector shaft and on the housing. Install and tighten the attaching bolts to specification.
41. Pack the seal adapter outer seal with C2AZ-19585-A, then install it on the adapter to prevent water entry.

FINAL CHECKS

1. After rotating the input shaft through its full travel for a minimum of five cycles, recheck the sector shaft adjustment. No rotational lash or bind of the sector shaft in center position is permissible.
2. If the gear is properly assembled and adjusted, the input torque of the empty gear should not exceed 15 in-lbs over full travel of 95 degrees at the output shaft.
3. Reverse-torque applied to output shaft for full gear travel should not exceed 50 ft-lbs.

DESCRIPTION

POWER STEERING PUMP

The Ford-Thompson power steering pump is a belt driven slipper type pump which is integral with the reservoir (Fig. 1). It is constructed so that the reservoir is attached to the rear side of the pump housing front plate and the pump body is encased within the reservoir (Fig. 2).

An identification tag is located behind the outlet fitting nut. Figure 3 shows typical tags. The top line on the tag indicates the basic model number (HBA) and the suffix. It is important that the codes on the tag are checked when requesting service parts as there may be slight differences in internal components.

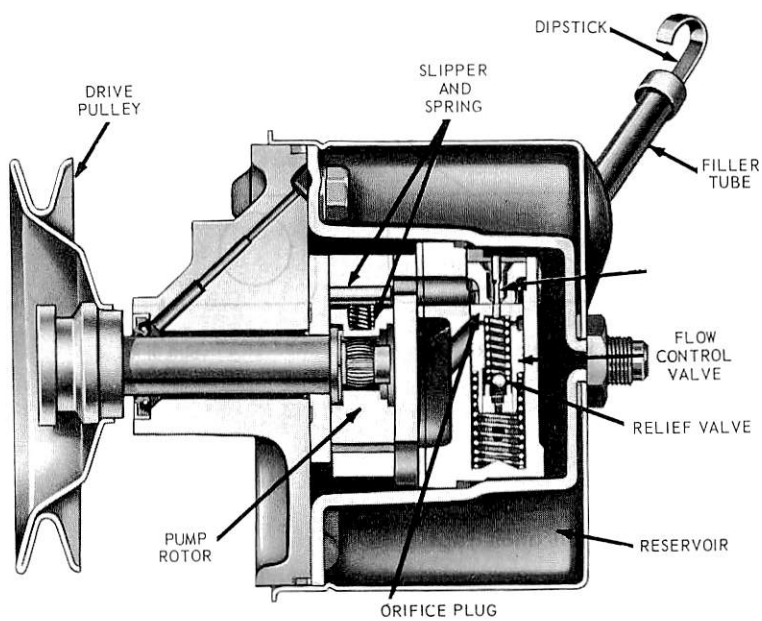

FIG. 1 Power Steering Pump — Sectional View

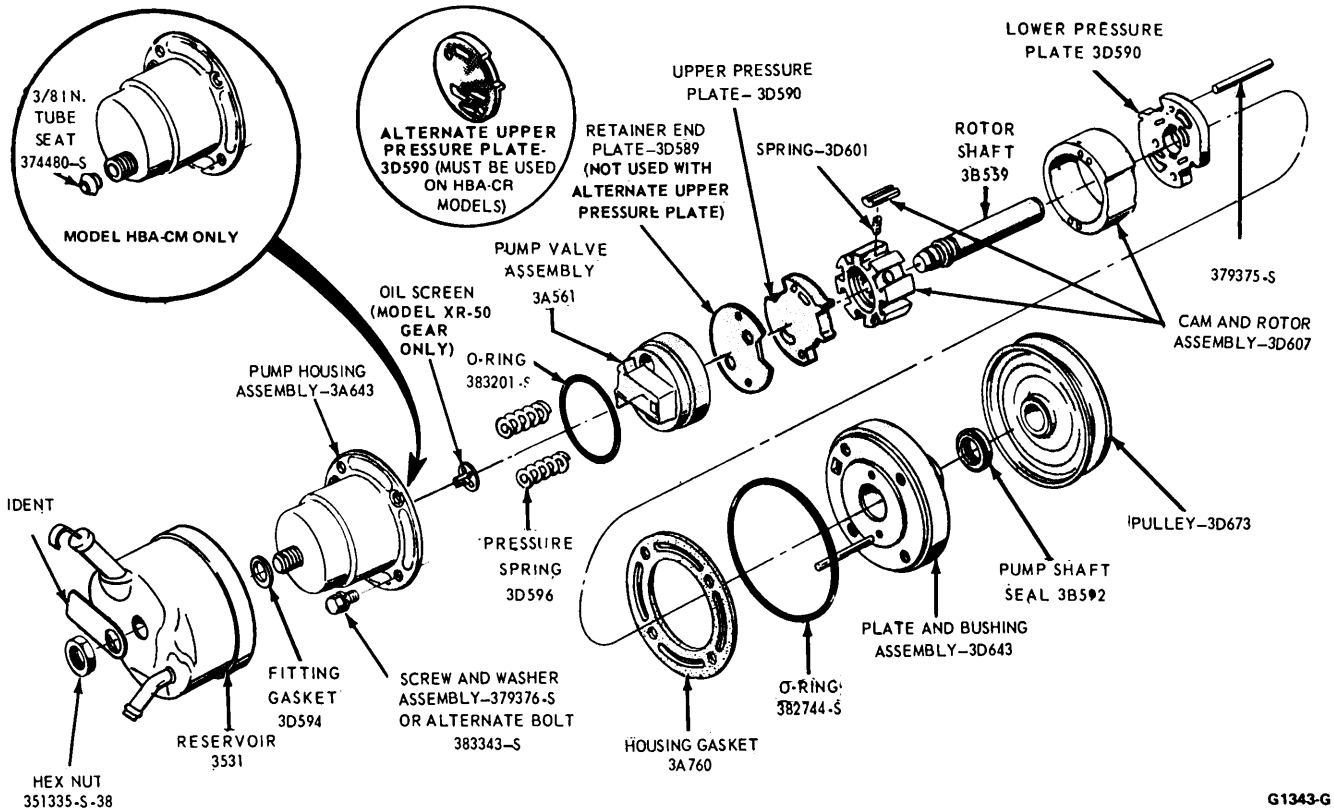

FIG. 2 Power Steering Pump—Disassembled

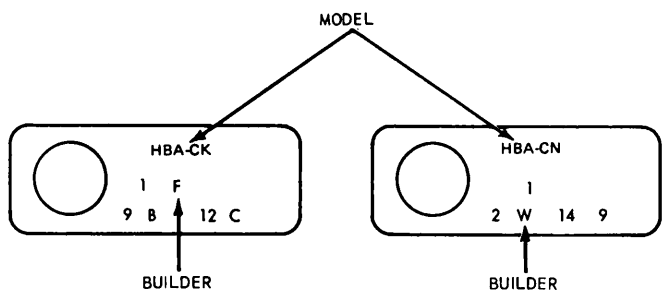

FIG. 3 Pump Identification Tags

ADJUSTMENTS

PUMP BELT TENSION ADJUSTMENT

Pump drive belt tension cannot be checked accurately using the thumb pressure or belt deflection methods. Correct belt adjustment is assured only with the use of a belt tension gauge.

1. Check the belt tension with a belt tension gauge Tool T63L-8620-A. With a new belt, or one that has been run for less than 15 minutes, the tension should be within 120-150 lbs. With a belt that has been run for more than 15 minutes, the tension should be within 90-120 lbs.
2. To adjust the belt, loosen the three screws on the pump adjusting bracket. On F-100-350, Bronco vehicles, apply leverage at the web on the hub side of the pump. On

Econoline vehicles, use Tool T71P-3D643-B from under the unit to apply leverage.

Do not pry against the reservoir to obtain proper belt load as it can be deformed and cause a leak.

3. Recheck the belt tension. When the tension has been correctly adjusted, tighten the bolts and the nut to specification.

POWER STEERING PUMP DRIVE BELT REPLACEMENT

1. Loosen the idler pulley attaching bolts and remove the compressor drive belt if equipped with an air conditioner.
2. Loosen 3 bolts and one nut attaching the power steering pump to the pump bracket, and remove the pump drive belt.
3. Position the power steering pump drive belt on the pulleys.
4. Adjust the drive belt tension as outlined in this section to specification and tighten the pump attaching bolts and one nut to specification.
5. Install the compressor drive belt if equipped with an air conditioner and adjust to specification (Group 36).

REMOVAL AND INSTALLATION

POWER STEERING PUMP

F-100-350

Removal

1. Loosen the pivot bolt (top) and the two adjustment bolts (lower) and remove the drive belt.
2. Disconnect the pressure and the fluid return hose from the rear of the pump.
3. Remove the pivot bolt and the two adjustment bolts that secure the pump to the bracket and remove the pump.

Installation

1. Position the pump to the bracket and install but do not tighten the two adjustment bolts and one pivot bolt.
2. Connect the pressure hose and the fluid return hose to the fittings at the rear of the pump (Fig. 4).
3. Place the drive belt on the crankshaft pulley and the pump pulley.
4. Place a wrench on the adjustment web and apply leverage to obtain the specified belt tension using Tool T63L-8620-A and tighten the adjustment bolts and pivot bolt to specification.
5. Fill the system with the proper fluid to the fill mark on the dipstick.
6. Start the engine and turn the wheels from stop-to-stop to bleed air from the system and check for fluid leaks. **Do not hold the wheels against the stops. Check the fluid level in the reservoir and add fluid D2AZ-19582-A if necessary.**

START-UP PROCEDURE (AFTER POWER STEERING PUMP OVERHAUL)

Upon initial engine start-up after a power steering pump overhaul, there is very frequently much noise and aeration. This is due to air trapped in the overhauled unit which mixes with the surging fluid and causes aeration. The problem can be minimized if the following procedure is used.

1. Disconnect the coil wire.
2. Fill the reservoir.
3. Crank the engine with the starter and continue adding fluid until the level remains constant.
4. Rotate the steering wheel approximately 30 degrees each side of center while continuing to crank the engine.
5. Recheck the fluid level and fill as required.
6. Reconnect the coil wire.
7. Start the engine and allow it to run for several minutes.
8. Rotate the steering wheel from stop to stop.
9. Shut off the engine and recheck the fluid level — add as required.

ECONOLINE

Removal

1. Raise the vehicle on a hoist.
2. Place a drain pan beneath the vehicle and disconnect the return and pressure lines at the pump. Lower 6 cylinder vehicles.
3. Loosen the power steering pump retaining bolts and position the drive belt out of the way.
4. Disconnect the reservoir hose from the pump.
5. On 6 cylinder vehicles: Remove the 4 nuts retaining the pump bracket to the cylinder block (Fig. 5). Remove the pump and bracket from under the vehicle.

On 8 cylinder vehicles: Remove the 3 bolts retaining the pump to the mounting bracket and lay the pump on the crossmember. Loosen mounting bracket retaining bolts and nuts allowing the bracket to move forward and remove the pump from the vehicle.

Installation

1. On 6 cylinder vehicles: Install the pump bracket to the pump with the 4 retaining bolts. Position the pump and bracket assembly (including spacers) on to the cylinder block mounting studs and install the 4 retaining nuts.

On 8 cylinder vehicles: While holding the pump bracket forward, place the pump into the chassis and tighten the bolts and nuts retaining the bracket to the engine. Position the pump to the bracket and install the 3 retaining bolts.

2. Connect the reservoir hose to the pump.
3. Raise 6 cylinder vehicles. Connect the pressure and return lines to the pump.
4. Reposition the drive belt to its pulleys. Adjust the drive belt tension and tighten the retaining bolts.
5. Lower the vehicle.
6. Fill the power steering system, cycle and check for leaks.

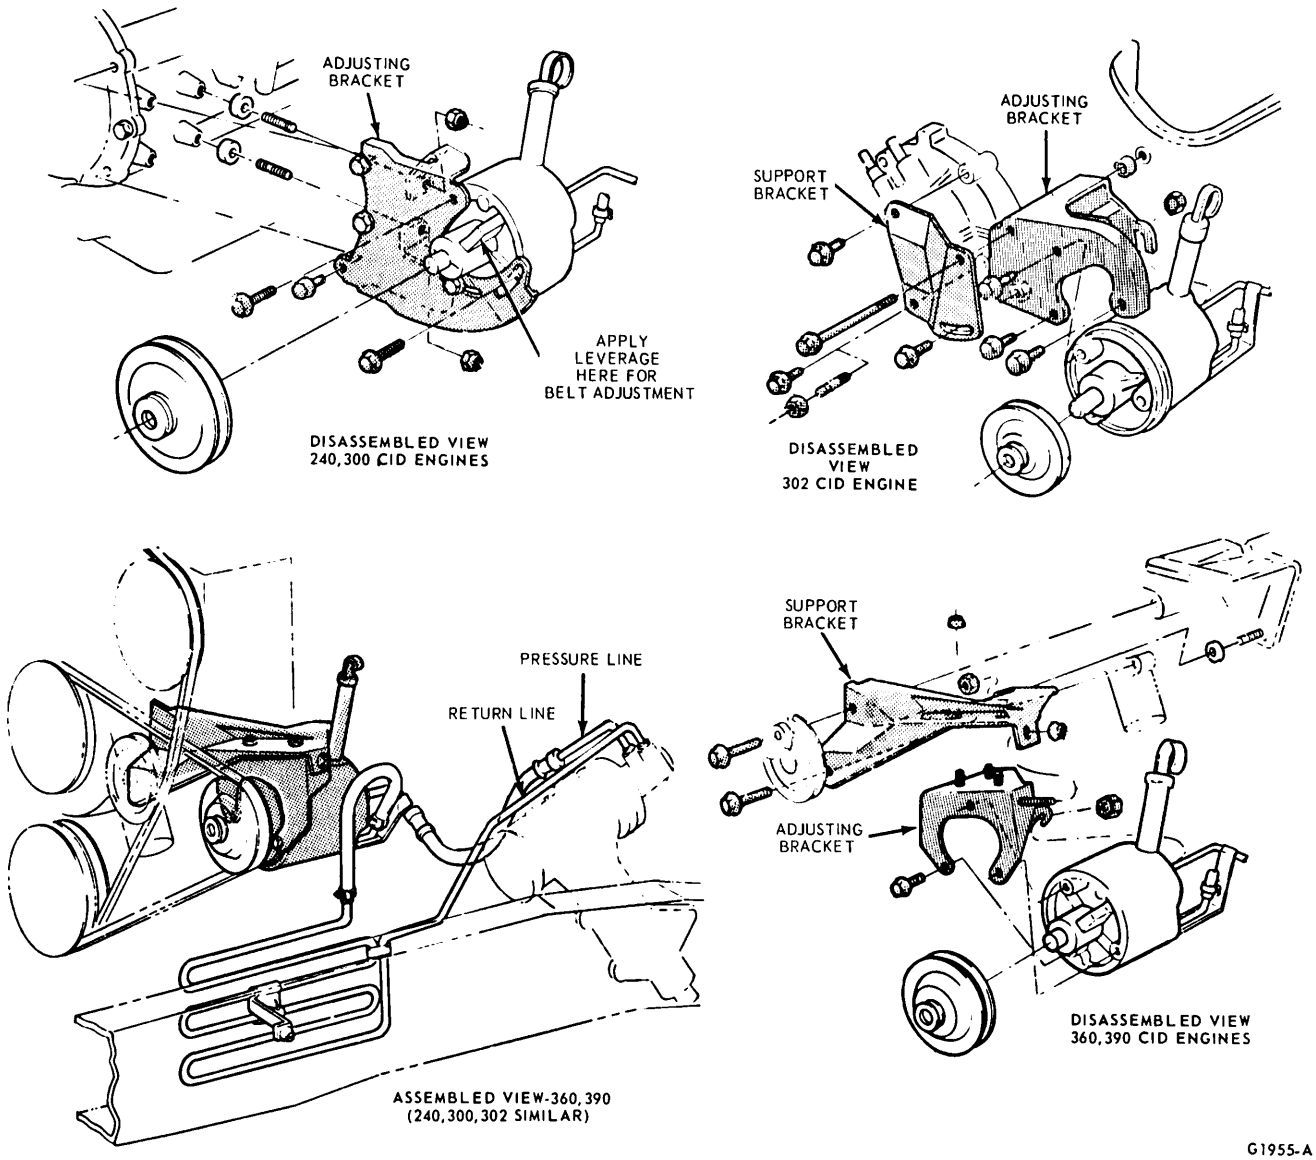

FIG. 4 Power Steering Pump Installation—F-100-350

Refer to Start-Up Procedure at the end of the first Removal and Installation procedure.

BRONCO

Removal

1. Position a drain pan under the power steering pump.
2. Disconnect the pressure and return lines at the pump. Disconnect the cooler hoses over the pump (Fig. 6).
3. Loosen the 1 pivot bolt and 1 adjustment bolt. Remove the drive belt.
4. Remove the 2 water pump bolts from the adjusting bracket attached to the front cover.
5. While holding the pump, use a jam nut and remove the through bolt from the cylinder head. Remove the pump with both brackets from the vehicle.

Installation

1. If installing a new pump, transfer the pump support bracket to the new unit.
2. Insert the through bolt from the rear of the pump bracket. Install the pump in the vehicle without the adjusting bracket, inserting the throught bolt into the block.
3. Position the adjusting bracket to the water pump and torque the 2 retaining bolts to specification (11-16 ft-lb.)
4. Install the bolt. Install and torque the bolts retaining the support bracket to the pump and block (30-40 ft-lb.) Check the belt tension.
5. Connect the cooler hoses over the pump (10-18 in-lb clamp torque). Connect pressure and return lines to the pump.
6. Fill the power steering system, cycle and check for leaks.
7. Remove the drain pan.

Refer to Start-Up Procedure at the end of the first Removal and Installation procedure.

ROTOR SHAFT SEAL

Removal

1. Remove the pulley from the rotor shaft as described under Power Steering Pump Pulley Removal.
2. Position the pump assembly in the bench mounted holding fixture, T57L-500-A or on the assembled adapter plate, T69P-3A674-A, pulley end of the shaft up.
3. Clean any rust or road dirt from the pulley end of the rotor shaft.
4. To prevent scoring of the shaft, wrap .005 shim stock (free of burrs) around the rotor shaft and push it

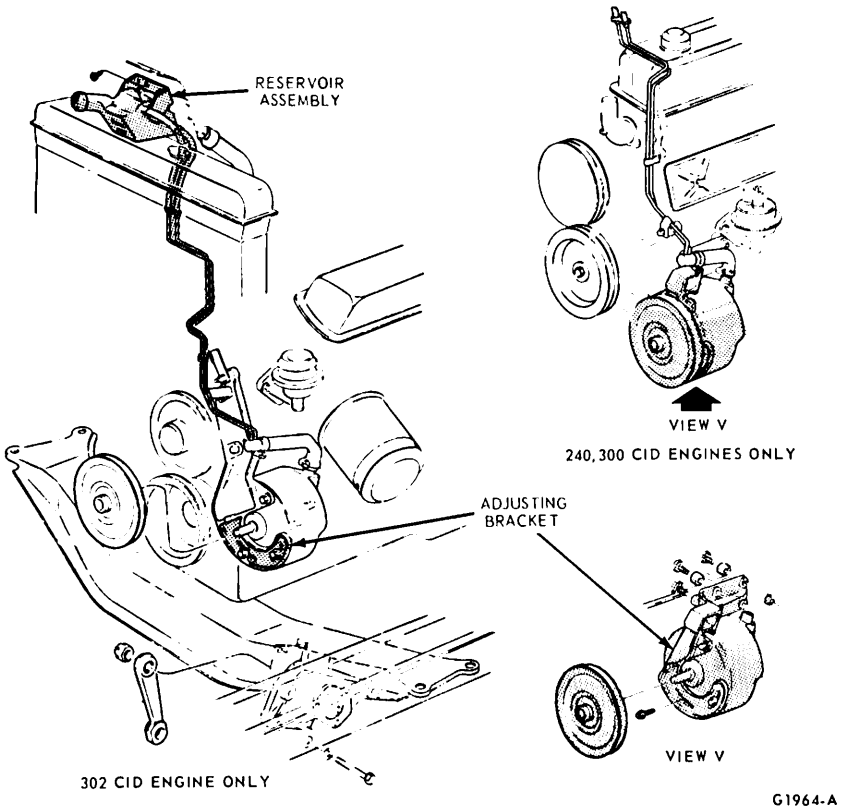

FIG. 5 Power Steering Pump Installation—Econoline

into the ID of the seal until it is against the bushing.

5. Using a sharp tool such as a sheet metal punch, carefully pierce the metal seal body face and pry the old seal out (Fig. 7). **Do not damage the bushing, the housing or the rotor shaft.**

Installation

1. Remove the shim stock.
2. Position the new rotor shaft seal on the shaft seal protector, Tool T68P-3B592-B.
3. Insert the seal protector tool and the rotor shaft seal onto the shaft (Fig. 8).
4. Using the seal installation Tool T68P-3B592-A and a rubber or plastic hammer, tap gently on the end of the tool until the seal is completely installed (flush with the end of the seal bore).
5. Remove the tools.
6. Install the pulley on the rotor shaft as described under Power Steering Pump Pulley Installation.

POWER STEERING PUMP PULLEY

Removal

1. Drain as much of the fluid as possible from the pump through the filler pipe.
2. Install a 3/8-16 inch capscrew in the end of the pump shaft to prevent damage to the shaft end by the tool screw.
3. Install the pulley remover, Tool T69L-10300-A, on pulley hub, and place the tool and pump in a vise as shown in Fig. 9.
4. Hold the pump and rotate the tool nut counterclockwise to remove the pulley (Fig. 9). **The pulley must be removed without in and out pressure on the pump shaft to prevent damage to internal thrust areas.**

Installation

1. Position the pulley to the pump shaft and install Tool T65P-3A733-A as shown in Fig. 10.
2. Hold the pump and rotate the tool nut clockwise to install the pulley on the shaft. The pulley face will be flush with end of pump shaft. **Install the pulley without in and out pressure on the shaft to prevent damage to internal thrust areas.**
3. Remove the tool.

POWER STEERING PUMP RESERVOIR

Reservoir replacement must be done on a clean workbench. Cleanliness of work area and tools is extremely important when repairing any hydraulic unit. Thoroughly clean the exterior of the pump with a suitable cleaning solvent. **Do not clean, wash or soak the shaft oil seal in solvent. Plug the inlet and outlet opening with plugs or masking tape before cleaning the pump exterior or removing the reservoir.**

Removal

1. Assemble the adapter plate (Tool T69P-3A674-A) to the bench mounted fixture tool (T57L-500-A). Position the pump and pulley on the adapter plate, pulley facing down.
2. Remove the outlet fitting hex nut and the service identification tag.
3. Invert the pump so the pulley is facing up and remove the reservoir by tapping around the flange with a wood block (Fig. 11).
4. Remove the reservoir O-ring seal and the outlet fitting gasket from the pump.

Installation

1. Install a new gasket on the outlet fitting and a new reservoir O-ring seal on the pump housing plate (Fig. 12).**The old gasket and seal should never be re-used.**
2. Apply vaseline to the reservoir O-ring seal and to the inside edge of the new reservoir flange. **Do not twist the O-ring seal.**
3. Position the reservoir over the pump and align the notch in the reservoir flange with the notch in the outer diameter of the plate and bushing assembly.
4. Install the reservoir on the pump and O-ring seal with a plastic or rubber hammer and a block of wood as shown in Fig. 13.**Tap at the rear of the reservoir and on the outer edges only.**
5. Inspect the assembly to be sure the reservoir is evenly seated on the pump housing plate.
6. Position the service identification tag on the outlet fitting and install the outlet fitting hex nut. Torque the nut to specification. **Do not exceed specification.**

DISASSEMBLY AND ASSEMBLY

POWER STEERING PUMP

Disassembly

Disassembly of the pump and its subassemblies must be made on a clean work bench. In repairing any hydraulically operated unit, cleanliness is of utmost importance. Clean the exterior of the unit with a suitable solvent and drain as much of the fluid as possible.

If only the reservoir is to be removed, plug the inlet and outlet openings with masking tape or plugs. Do not immerse the shaft oil seal in solvent. If only the rotor shaft seal is to be replaced, see Rotor Shaft Seal Replacement outlined in this section.

1. Assemble the adapter plate (Tool T69P-3A674-A) to the bench mounted holding fixture Tool T57L-500-A (Fig. 14).
2. Position the pump assembly, with pulley assembled, on the adapter plate, pulley facing down.
3. Remove the outlet fitting nut and the service identification tag.
4. Invert the pump assembly and, using a block of wood and a rubber or plastic hammer, remove the pump reservoir and seal by tapping around the flange of the reservoir and on the underside of the filler neck.
5. Again invert the pump assembly, loosen and remove the pump housing retention bolts and remove the pump housing.
6. If necessary, remove the following components from the pump housing: the housing cover, the O-ring seal, the oil screen (if so equipped) and the pressure springs. These components normally will remain in the pump housing when it is removed.
7. Remove and discard the pump cover gasket.
8. Remove the retainer end plate and upper pressure plate (in some pumps, the end plate and upper pressure plate are integral).
9. Remove the loose fitting dowel pin. be careful not to bend the fixed dowel pin which remains in the housing plate assembly.

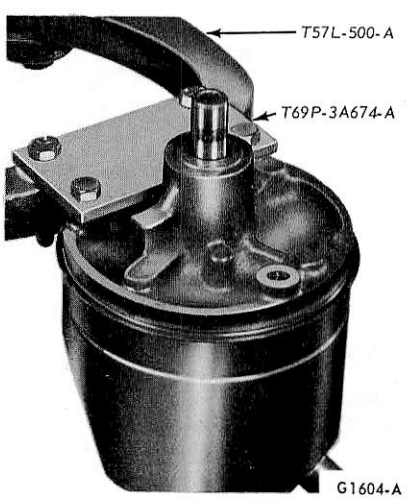

FIG. 14 Adapter Plate Installation

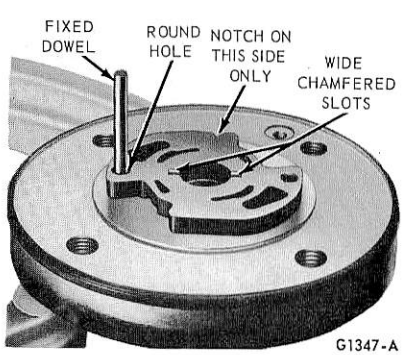

FIG. 15 Lower Pressure Plate Installed

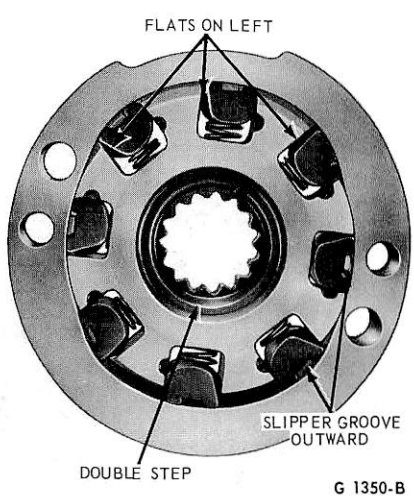

FIG. 16 Correct Slipper Installation

10. Remove the rotor assembly being careful to prevent the springs and slippers from falling out and becoming lost. Do not disassemble further unless the lower pressure plate, housing plate, rotor shaft and/or seal is to be replaced.
11. Invert the pump assembly and, using Tool T69L-10300-A, remove the pulley.
12. Clean any rust, road dirt, burrs, scoring, etc., from the pulley end of the rotor shaft prior to removal of the shaft from the housing plate. The shaft must come out without restrictions to prevent scoring or damage to the bushing. Remove the pump rotor shaft.
13. Remove the lower pressure plate.

Assembly

1. Assemble adapter plate (Tool T69P-3A674-A) to the bench mounted holding fixture Tool T57L-500-A. Position the pump assembly on the adapter plate, pulley side facing down. (If the lower pressure plate and rotor shaft have not been disassembled, omit Steps 2 and 3).
2. Insert the lower pressure plate on the anchor pin with the wide chamfered slots at the center hole facing up (Fig. 15).
3. Dip the rotor shaft in specified power steering fluid D2AZ-19582-A; Then, insert the rotor shaft through the lower pressure plate and housing plate.
4. If the rotor assembly is disassembled, hold the cam insert with the notch on the OD of the cam at the top and the arrow or the open end of the vendor letter mark on the OD of the cam pointing downward.
5. Insert the rotor in the cam with the double step in the ID of the rotor facing upward.
6. With the rotor extended upward approximately one half way out of the cam, insert a spring into a rotor spring pocket working in the rotor cavity directly beneath the cam notch.
7. Use one of the slippers to compress the spring and install the slipper with the groove in the slipper facing upward (toward the cam notch). The flats on the side of the slipper should be on the left (Fig. 16).
8. Hold the cam stationary and turn the rotor either to the right or left, one space at a time. Repeat Step 7 until all the rotor cavities have been filled. Be careful when turning the rotor that the springs and slippers already inserted do not fall out.
9. Install the cam and rotor assembly onto the pump housing plate with the fixed dowel passing through the first hole to the left of the cam notch when the arrow on he cam OD is pointing toward the lower pressure plate (Fig. 17). If the cam and rotor assembly will not seat, turn the rotor shaft slightly until the spline teeth mesh, allowing the cam and rotor to drop down into position.
10. Insert the loose fitting dowel through the cam insert and lower plate into the hole in the housing plate assembly. When the loose dowel is properly installed the heights of the two dowels must be equal. Squirt the rotor, springs, slippers and cam insert with C1AZ-19582-A lubricant.
11. Place the upper pressure plate with the face having the tapered notch down against the cam insert. The fixed dowel should pass through the round dowel hole and the loose dowel through the elongated hole. The slot between the ears on the pressure plate OD should match the notch on the cam insert OD (Fig. 18).
12. Install the retainer end plate so the slot on the end plate OD matches the corresponding notches of the upper pressure plate and cam (Fig. 19).
13. Install the pump valve assembly O-ring seal onto the pump valve assembly being careful not to twist the seal (Fig. 20).
14. Place the pump valve assembly on top of the retainer end plate with the large exhaust slot on the pump valve in line with the OD notches of the previously assembled parts. The stack of parts must be fully seated. If the pump valve has been installed correctly, the relief valve stem will be in line with the lube return hole in the pump housing plate (Fig. 20).
15. Install the oil screen assembly (if so equipped) into the pump housing with a suitable socket. Place small amounts of vaseline on the pump housing plate to hold the cover gasket in place. Install the gasket on the pump housing plate.
16. Insert the pressure plate springs into the pockets in the pump valve assembly. Vaseline may be placed in the spring pockets to hold the springs in position (Fig. 21).
17. Using Tool T69P-3B586-A, plug the intake hole in the housing (Fig. 22).
18. Lubricate the inside of the housing and the housing cover seal with D2AZ-19582-A lubricant. Fabricate two studs (3/8-16 x 1.55) to be used as positioning guides. Install one in the housing plate bolt hole closest to the drain hole and one in the bolt hole diametrically opposite.
19. Align the small diameter lube hole in the housing rim with the lube hole in the housing plate.
20. Install the housing, applying an even, downward pressure. The pressure plate springs **must not** be jarred and moved out of position. Remove the guide studs.
21. Install the housing retaining bolts finger tight.
22. Remove tool T69P-3B586-A.
23. Torque the retaining bolts to specification until the housing flange contacts the gasket.
24. Install a 3/8 x 16 hex head screw, finger tight, into the end of the rotor shaft. Using a torque wrench, check the input torque of the shaft (Fig. 22). The torque should not exceed 15 in-lbs. If it does, loosen he retaining bolts slightly, rotate the rotor shaft, retorque the bolts evenly and again check the shaft torque. **The pump must not be used if the shaft torque exceeds 15 in-lbs.**
25. Release the pin in the bench holding fixture and agitate the pump assembly back and forth. If there is a rattle, the pressure plate springs have fallen out of their seats and must be reinstalled.
26. Install the reservoir O-ring on the housing plate being careful not to twist the O-ring. Apply vaseline to the seal and to the ID of the reservoir flange.
27. Install the reservoir, aligning the notch in the reservoir flange with the notch in the OD of the pump housing plate and bushing assembly. Using only a plastic or rubber hammer, tap at the **rear on the outer corners of the reservoir to avoid damage.**
28. Inspect the assembly to determine if the reservoir is seated on the housing plate.
29. Install the service identification tag on the outlet valve fitting.
30. Install the outlet valve fitting nut and torque to 43-47 ft-lbs.
31. Invert the pump assembly.
32. If the pulley was removed, install the correct pulley using Tool T65P-3A733-A.

POWER STEERING PUMP		Filter Element Replacement	51-07
Disassembly and Assembly	51-05		
Removal and Installation	51-01	SHAFT SEAL INSTALLATION	51-02

DESCRIPTION

POWER STEERING PUMP

The medium duty Eaton power steering pumps are single stroke roll vane types. The reservoir can either be mounted to the top of the pump body or mounted remotely and connected with a hose to an adapter bolted to the top of the pump body.

The heavy duty Eaton pumps are hydraulically balanced roll vane types with pressure balanced end plates. Normally the reservoir is attached to and surrounds the pump. There is a special reservoir with an inlet tube (lower section only) for the pumps to be used when the reservoir is remotely mounted.

The pumps can be either belt or gear driven.

REMOVAL AND INSTALLATION

When performing any service operations on power steering systems which necessitate hose disconnecting, make certain the hoses are tagged prior to removal. It is important that the hoses are reconnected to their correct ports to preclude damage to the system.

For pump installations, see Figures 1 through 7.

POWER STEERING PUMP

Removal

1. Using a suction gun, remove as much fluid as possible from the reservoir through the filler opening.
2. Disconnect the pressure hose from the pump and disconnect the return line from the cooler or reservoir. Then fasten both hoses in a raised position to prevent the fluid from draining out. **On a C-Series truck, the hoses can be more easily disconnected after the pump has been removed from its bracket and is resting on the frame member.**
3. After loosening the adjusting bracket bolt and the pivot bolt, remove the pump belt. Then remove the bolts, and remove the pump and fluid reservoir together.

Installation

1. Hold the pump and fluid reservoir and the adjusting bracket on the pump support, and install the mounting bolts and washers. Tighten the bolts finger-tight.
2. Place the pump belt on the crankshaft pulley and pump pulley, and tighten the belt.
3. Adjust the pump belt tension. When the tension is correct (150 lbs per strand on single belt drives; 100 lbs per strand on dual belt drives), torque the adjusting bolts and the pivot bolt to specifications.

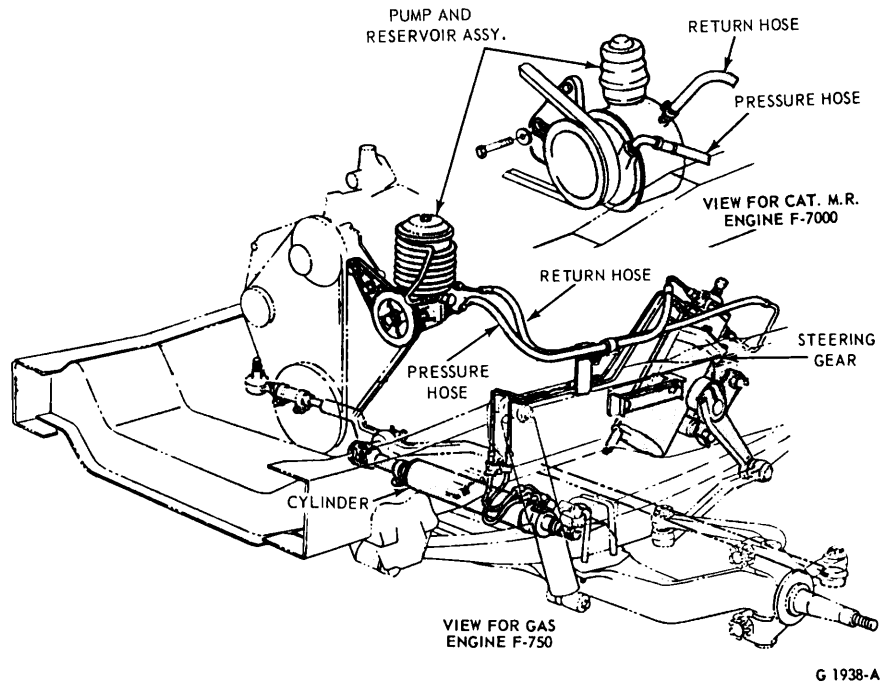

FIG. 1 Power Steering Pump Installation — F-750-7000 with 9000 lb. Axle (F-B-500-750-6000-7000, LN-750 With 9000 lb. Axle Similar)

4. Connect the two hoses to the pump and fluid reservoir. It is important to be sure that all power steering lines are connected to the correct ports.
5. Fill the fluid reservoir to specification with automatic transmission fluid.
6. Start the engine and run it at idle speed for about two minutes to warm the fluid in the power steering system. Check the fluid level and add if necessary.
7. Turn the steering wheel all the way to the left and right several times, and check the system for fluid leaks.
8. Increase the engine speed to about 1000 rpm, in turn the steering wheel all the way to the left and right several times. Do not hold the wheels against the stops.
9. Stop the engine, and check the pump, reservoir, and hose connections for fluid leaks. Correct the cause of any leaks. Add fluid if necessary.
10. Turn the steering wheel as required to place the front wheels in the straight ahead position. Check the fluid level, and refill the reservoir if necessary.

POWER STEERING PUMP SHAFT SEAL

Removal and Installation

If the shaft seal was removed from the pump housing, install a new seal. **Do not install the old seal.**

1. Coat the lip of a new seal with Lubriplate or an equivalent lubricant.
2. Position the seal in the bore of the housing. **The lip of the seal must face toward the pump housing carrier chamber.**
3. Press the seal into the housing (Fig. 8) until it seats firmly and evenly against the shoulder in the bore.

DISASSEMBLY AND ASSEMBLY

POWER STEERING PUMP

C-B-F-LN-500-750

Disassembly

Handle all parts very carefully to avoid nicks, burrs, scratches and dirt which could make the part unfit for use.

1. On vehicles with a pump-mounted reservoir, remove the reservoir cover from the reservoir. Then, drain as much of the remaining fluid as possible from the pump and clamp the pump adjusting bracket in a vise. On vehicles with a remote reservoir, disconnect the fluid supply hose at the pump and plug the hose.
2. Disconnect the cooling coil at the pump.
3. If the vehicle is equipped with a pump-mounted reservoir, remove the filter element support bolt and the reinforcement plate (Fig. 9). Lift the reservoir off the pump.
4. Remove the four O-rings from the top of the pump (Fig. 10). Remove the pulley and the pulley key from the shaft. Loosen the pump valve retainer.

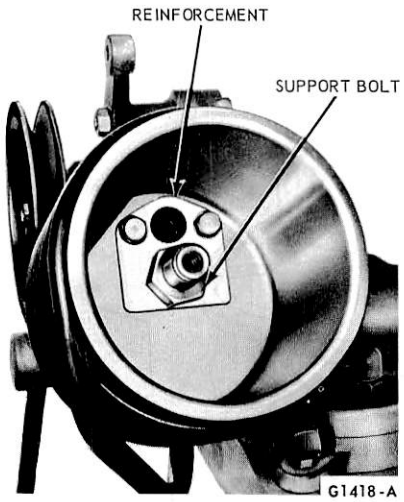

FIG. 9 Reservoir Installation

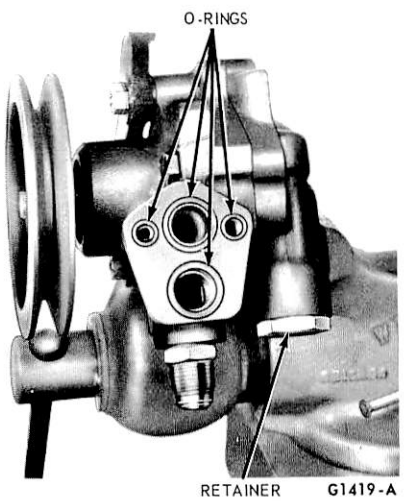

FIG. 10 Reservoir O-Rings

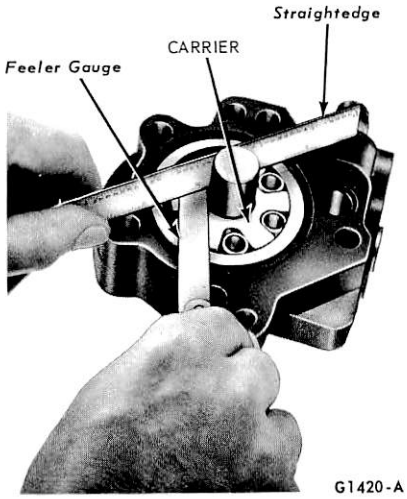

FIG. 11 Checking Carrier and Roller and Clearance

5. Remove all the bolts from the pump, and separate the bracket, pump housing, and housing cover. If the parts do not pull apart easily, tap them gently with a soft hammer to loosen them. Lift the cover vertically from the housing to prevent internal parts from falling out.
6. Remove the O-rings from the pockets around the by-pass hole and the cam insert. All parts should be washed and inspected.
7. Using a feeler gauge and a straightedge, check the end clearance of the carrier and the rollers in the pump housing (Fig. 11). If the clearance exceeds 0.0015 inch, replace the worn parts. A damaged roller, carrier or insert should not be replaced by itself; these parts are serviced in a kit, and all parts of the kit should be used.
8. Remove the rollers, slide the carrier off the shaft, and remove the carrier drive pin. If the carrier is to be reused, note the original assembly position to assure correct reassembly. Remove the cam insert. Be sure to remove the small cam locating pin in the bottom corner of the cam pocket.
9. Remove the bearing retainer ring (Fig. 12), and tap the bearing and shaft assembly out of the pump housing.
10. Remove the pump valve retainer, spring and the valve from the pump cover. If the valve does not slide out easily, tap the cover with a soft hammer. Remove the O-ring from the retainer.

Assembly

During assembly of the pump, coat all moving parts and friction surfaces with automatic transmission fluid.

1. Install the shaft and bearing assembly in the pump housing taking care not to damage the seal; then, install the bearing retainer.
2. Install the cam insert so that the slot in the edge of the insert engages the pin in the pump housing.
3. Install the carrier drive pin on the pump shaft and then assemble the carrier on the shaft. The driving edges of the carrier must face in the direction of pump rotation (Fig. 13).
4. Install new O-rings in the recesses around the by-pass hole and the cam insert (Fig. 13). Install the rolls in the slot in the carrier. Attach the pump cover to the housing with two bolts.
5. Clamp the mounting bracket in a vise, and install the pump on the bracket.
6. Place the pulley key in the pump shaft, then install the pulley and the retaining bolt and washer. Torque the pulley bolt to specification. The pulley and pump shaft should rotate freely with no bind at any point after all bolts are tightened to specification.
7. Slide the pump valve into the bore in the cover. Place a new O-ring on the valve retainer, and install the pump valve spring and the retainer (Fig. 14).
8. On pump-mounted reservoir equipped vehicles, place new O-rings in the grooves in the top of the pump housing (Fig. 10). Hold the reservoir on the pump housing, and install the reinforcement plate and the support bolt (Fig. 9).
9. Install the filter element and the cover assembly. Connect the cooling coil at the pump.

L-W-SERIES WITH 8V-71, 6V-53, 6-71, NH, FT, SD, CUMMINS, CAT ENGINES

Disassembly

1. Drain most of the oil from the pump reservoir by disconnecting the pressure line from the steering gear and allow the pump to drain into a 1-gallon (minimum) pan. Disconnect the return line from the reservoir.
2. On some units, it may be necessary to remove the pump from the vehicle. Then remove the two 9/16 inch hex nuts from the studs on the back of the reservoir.
3. Remove the two flat washers and spacers (if used) from around the studs. Remove the two studs (Fig. 15).
4. Tap the reservoir with the palm of the hand so it rotates slightly around the pump body. Carefully rock the reservoir back and forth and remove it from the pump. **Do not use any tool to pry the reservoir off.**
5. If removing the pulley from the pump, care must be taken to prevent damage to internal pump parts. The pulleys on some models have a groove on the center hub to accommodate a standard puller. Other models do not have the groove and Steps 6 and 7 should be followed.

Do not in any case exert a force either outward or inward on the pulley outside diameter or attempt to force the shaft into or out of the pump.

6. To remove the pulley, back out the pulley retaining bolt approximately 1/2 inch.
7. While holding the pump up by the pulley, gently tap on the head of the bolt. The pulley is a slight press fit

on the shaft and may require several taps for removal.
8. When replacing the pulley on the shaft, be careful the Woodruff key does not slip out of the keyway and up behind the pulley. There is a slight press fit between the pulley and the shaft for about the last 1/8 inch engagement.
9. Install the flat washer, the lock washer and tighten the pulley retaining bolt 15-20 ft-lb to pull the pulley in place.

FILTER ELEMENT

1. After the reservoir has been removed from the pump, place the reservoir face up on a work bench. The filter element is positioned horizontally in the upper reservoir.
2. The filter is supported on one end by the filter spring and on the other end by the cap. These are supported by the return oil tube that projects inside the reservoir.
3. Remove the filter element by hooking the spring with a screwdriver or other suitable tool and pulling the spring and filter downward into the large opening.
4. Replace the filter by reversing the removal procedure using the fingers to feed the spring in place with the filter. Be sure the spring is properly positioned in the detent provided on the side of the reservoir.

Assembly

1. Install the two attaching studs finger-tight (1-10 ft-lb) into the pump.
2. Assemble a new sealing washer over each stud.
3. Install a new O-ring on the OD of the pump. Apply Lubriplate around the O-ring prior to assembling the reservoir to the pump.
4. Position the reservoir over the two studs and then push the reservoir forward over the large O-ring on the OD of the pump. Be sure the reservoir is positioned evenly and completely forward.
5. Install a new external sealing washer, spacer (if used) and retaining nut to each stud.
6. Tighten the retaining nuts to 20-30 ft-lb torque.
7. If the pump has been removed from the vehicle, reinstall it and attach the hose lines.
8. Fill the reservoir to the cold fill mark on the sight glass with specified fluid.

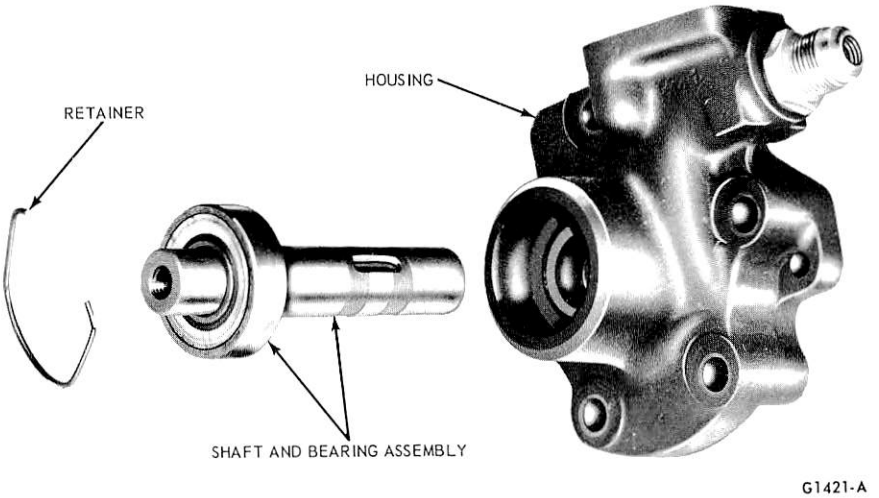

FIG. 12 Carrier Shaft and Retainer Disassembled

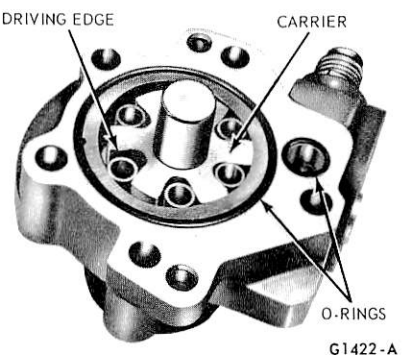

FIG. 13 Carrier and Roller Installation

9. Start the engine and run at idle speed for 2-3 minutes. Stop the engine and add fluid to the reservoir if necessary to bring the level to the cold fill mark again. Do not turn the steering wheel during the initial bleeding operation.
10. Turn the wheels slowly from side to side several times to completely bleed any air from the system.
11. With the wheels in a straight ahead position, stop the engine and once more check the fluid level. Add fluid if necessary but do not overfill the system.

TESTING

FRONT END ALIGNMENT CHECKS

E-100-300, F-100-350 VEHICLES WITH TWIN-I-BEAM FRONT SUSPENSION

Do not attempt to check and adjust front wheel alignment without first making a preliminary inspection of the front end parts.

Wheel alignment specifications and the method of checking caster, camber and toe alignment for Twin-I-Beam vehicles are made with the vehicle at normal operating height and attitude. The vehicle frame must be level across the front side to side when checking caster or camber. Check for toe alignment with vehicle as equipped.

Incorrect wheel alignment can cause tire wear. Abnormal or excessive tire wear can also be caused by wheel/tire unbalance or incorrect tire pressure. Typical tire wear patterns are shown in Fig. 1. These examples are only a guide: Incorrect toe alignment and extreme camber wear patterns resemble each other.

Toe alignment maladjustment, rather than caster or camber, is more likely to be the cause of excessive or uneven tire wear on vehicles with Twin-I-Beams. Toe alignment should be the first thing checked (and adjusted) to correct for excessive tire wear.

Checking Toe Alignment

Correct toe alignment is the inward pointing to both front wheels at the front.

1. Inflate all tires to the specified pressure.
2. Check the front axle pivot bushings and radius arm-to-frame bushings for excessive wear or deterioration. Replace if necessary.
3. Check the front wheel bearings and adjust if necessary.

FIG. 1 Tire Wear Conditions

4. Check both front tires. They should be the same size, ply rating, lead range and rolling radius. The axles must be level and can be checked by measuring the distance from spindle center to ground. If heights exceed 1/16 inch difference, add shims under the low side tire or deflate the high side tire. **Be sure to reinflate the tire to the specified pressure.**
5. If the alignment equipment being used attaches to the wheels, check and adjust the fixture for wheel runout.
6. Torque the spindle pin lock pin to 40-55 ft-lb.
7. Check the spindle pins and/or spindle bushings for evidence of excessive wear. Grasp each tire at the top and bottom and shake the wheel while watching the movement of the brake backing plate (or disc brake support). If the brake backing plate moves more than 1/32 inch, replace the spindle pins and bushing.
8. Check the toe alignment dimension with the wheels in the straight ahead position. Measure the distance between the extreme front and also between the extreme rear of both front wheels. Measure at an equal distance from the floor approximately at the center of the spindle. The difference between these two measurements is the amount the wheels toe-in (or toe-out). If the toe alignment is not within the 1/32 inch out to 7/32 inch in (F-Series) and 3/32 inch out to 5/32 inch in (E-Series) specification. **Do not attempt to adjust by bending suspension or steering linkage components.**

Checking Caster and Camber

The Twin-I-Beam front suspension design, used on all F-Series (4 x 4) and ESeries trucks, has caster and camber angles built-in and are non-adjustable.

Caster is the number of degrees of backward (positive) or forward (negative) tilt of the spindle (king) pin. Camber is the number of degrees the top of the wheel tilts outward (positive) or inward (negative) from a vertical plane.

Before checking caster or camber, perform the previously detailed toe-in check. Level the vehicle. Equal height blocks placed between the axle and frame may be used for leveling with appropriate ballasting or clamping as required. Measure from a similar point on the right and left frame side rail to the axle I-Beam top surface. Distances should be equal from side to side within 1/8 inch.

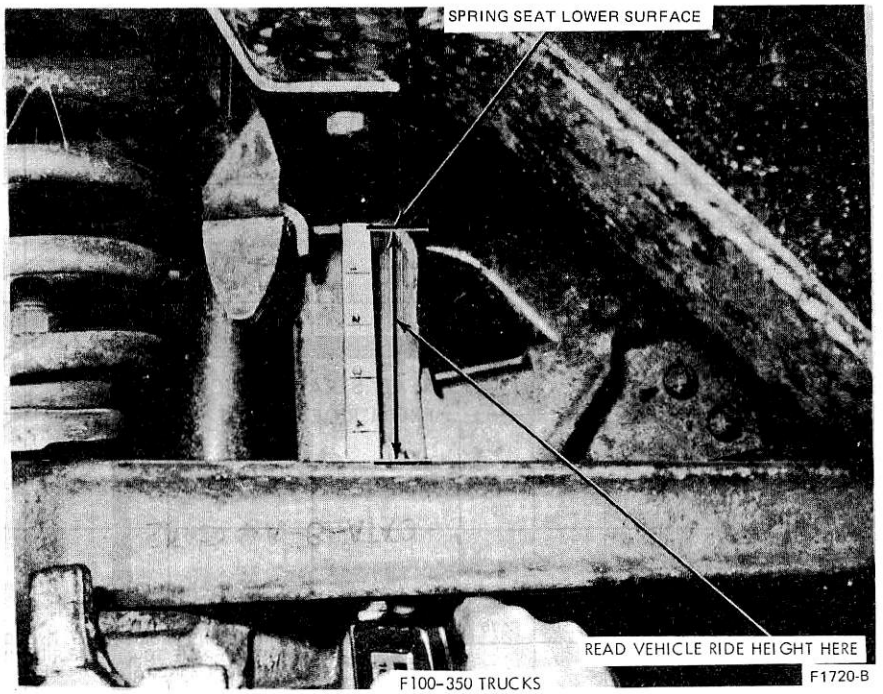

FIG. 2 Ride Height Measurement Procedure — F-100-350 Trucks

To determine the ride height of the F-100 through F-350 trucks, measure between the axle and spring seat lower surface (Fig. 2). On Econoline vehicles, measure between the axle and the bottom of the sill (Fig. 3).

Now measure the caster and camber with appropriate equipment. Be sure and follow the manufacturer's instructions. Figure 4 illustrates the step-by-step procedure for using the caster and camber angle charts (Figs. 5 and 6). Caster and camber specifications for Econoline and Light Trucks with Twin-I -Beam suspension are included in the Specification Section at the end of this Part.

Determine that the major difference between wheels is not caused by a non-level vehicle, worn pivots, a bent or loose spindle, etc. before making caster or camber alignment corrections.

To determine which wheel is truly out of specification once an excessive side-to-side variation has been verified, the caster and camber charts in Figures 5 and 6 must be used. They illustrate a band of values acceptable for a given ride height.

Having determined the vehicle ride height (Figs. 2 and 3), the appropriate caster and camber readings can be determined from Figures 5 and 6. The ride heights must be approximately

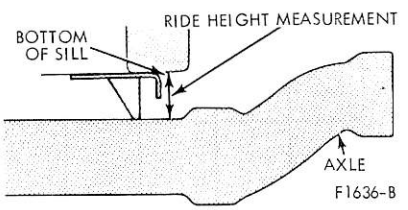

FIG. 3 Ride Height Measurement Procedure — Econoline

equal (within 1/8 inch) from side to side.

Caster is built into the I-Beams. Alignment equipment only indicates a true reading when the frame is horizontal, front to rear. If the frame is not level (due to tire, spring or load differences), the caster angle reading must be modified. If the front is higher than the rear, **subtract the amount of angle from the reading. If the front is lower than the rear, add the angle.**

On F-100-350 trucks, measure the frame angle with a spirit level protractor on he lower frame flange at the flat area immediately adjacent to the rear spring front hanger (Angle A, Fig. 7). On Econoline vehicles, take the measurement midway between the front and rear axles on the floor sidemember

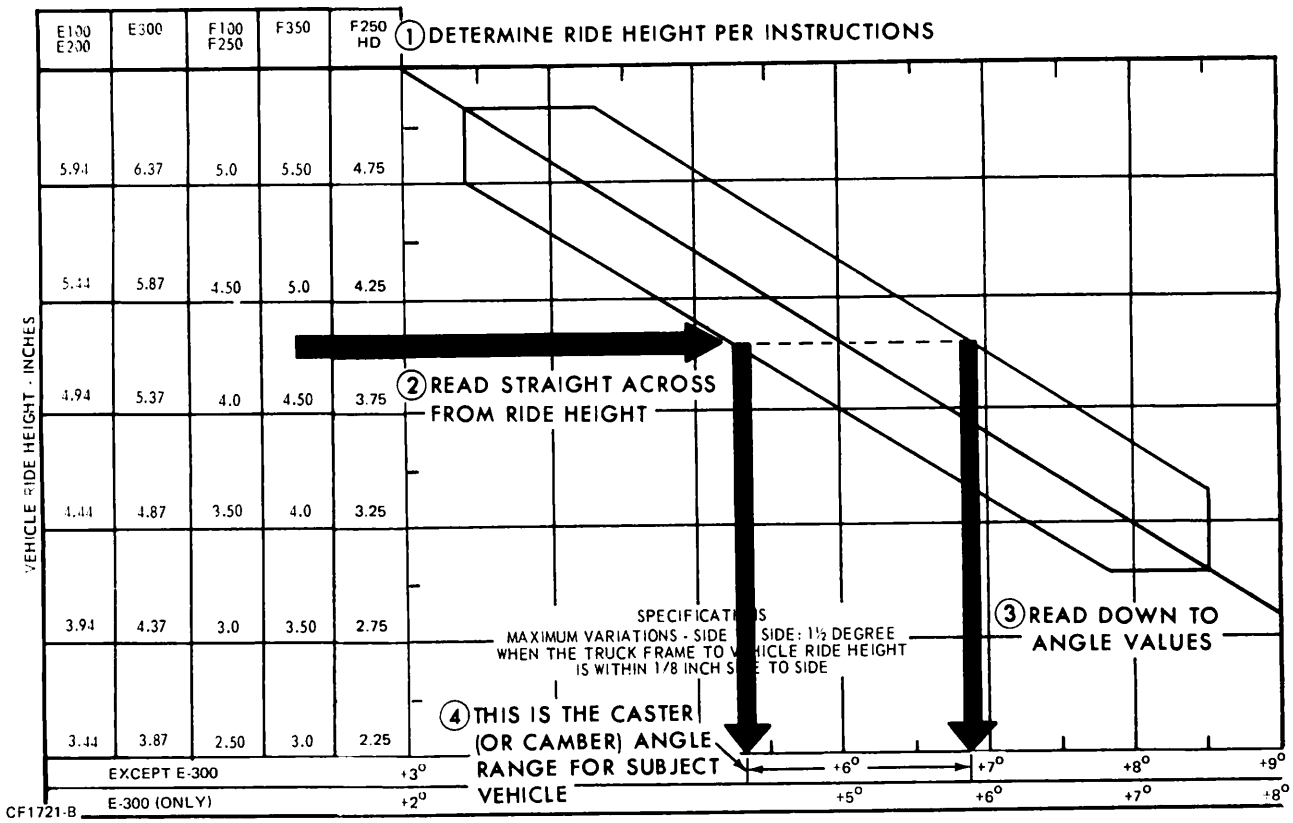

FIG. 4 Procedure for Using Caster and Camber Charts

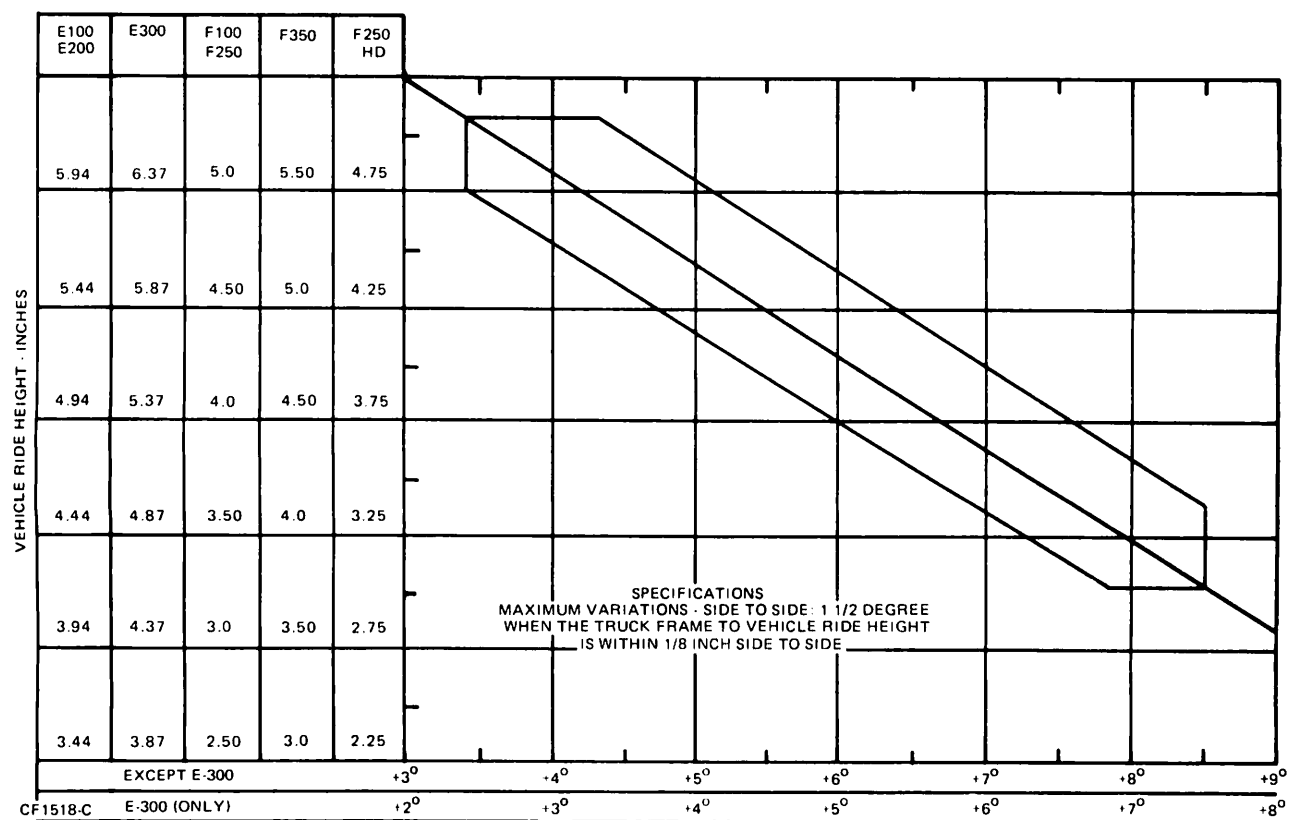

FIG. 5 Caster Angle Chart — Lt. Trucks, Econoline

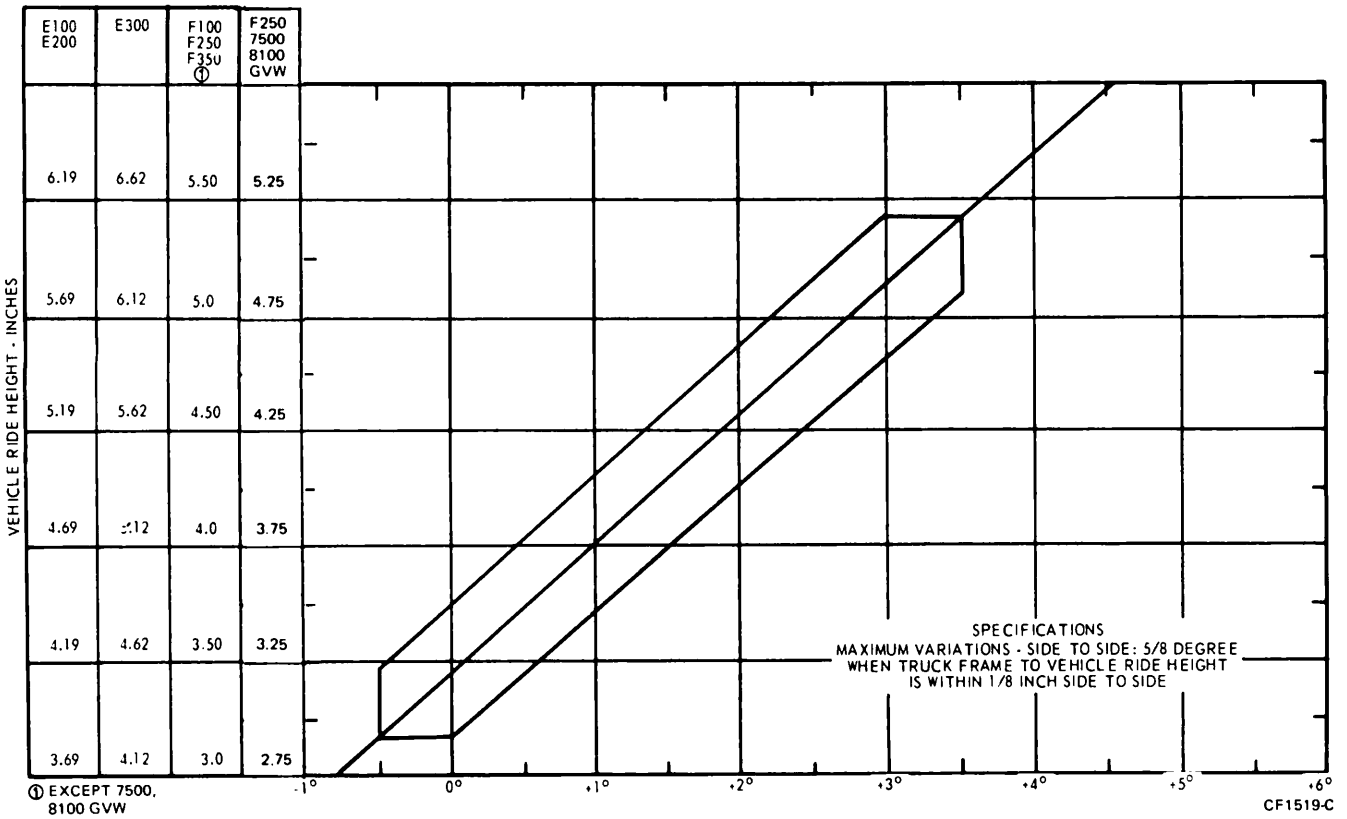

FIG. 6 Camber Angle Chart — Lt. Trucks, Econoline

sill assembly (Angle A, Fig. 7).

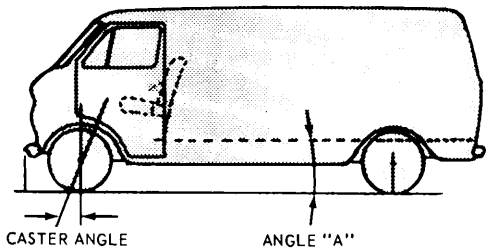
Alignment Adjustment

If toe alignment is not within the specified 1/32 inch out to 7/32 inch in (F-Series) and 3/32 inch out to 5/32 inch in (E-Series) dimension, adjust as follows:

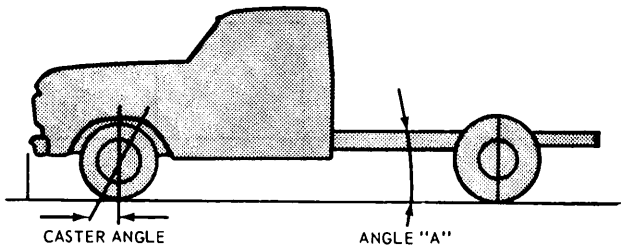
1. Loosen the clamp bolts at each end of the spindle connecting rod tube.
2. Rotate the tube until the correct toe alignment of 3/32 inch in (F-Series) or 1/32 inch in (E-Series) preferred is obtained. Tighten the clamp bolts. Recheck the toe alignment to make sure no changes occurred as the bolts were tightened.
3. Position the clamps 3/16 inch from the end of the rod. On F-100 through F-350, F-100 (4 x 4) and Bronco models, tighten the clamps with the bolts vertical and forward of the rod with the nuts facing downward.

F-100, 4-WHEEL DRIVE — BRONCO

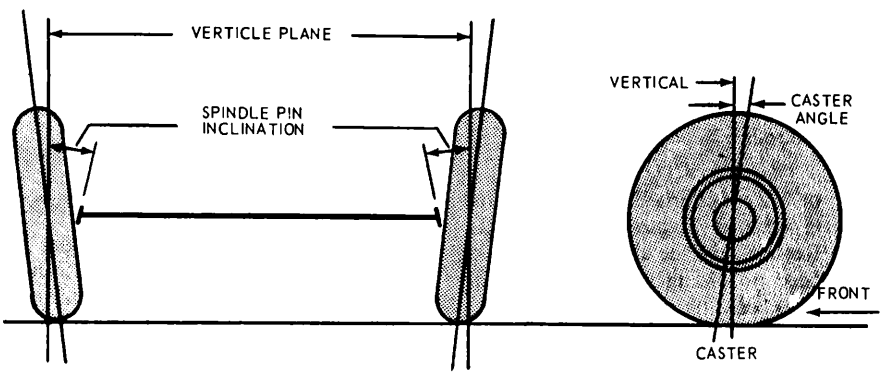
The caster and camber angles are designed into the front axle and cannot be adjusted. The checking procedure, use of specified blocks and determination of frame angle also apply to front drive axle vehicles.



MODEL E100-E300 TRUCKS



MODEL F100-F350 TRUCKS



F1520-B

FIG. 7 Front End Alignment Data — Lt. Trucks, Econoline

ADJUSTMENTS

FRONT WHEEL ALIGNMENT ADJUSTMENTS

After front wheel alignment factors have been checked make the necessary adjustments.

F-100, F-250, F-350, ECONOLINE, F-100 4-WHEEL DRIVE, BRONCO

The camber and caster angles are designed into the front axle and cannot be adjusted.

F-250 4-WHEEL DRIVE

The camber angle is designed into the axle and cannot be adjusted. The caster angle is adjusted with shims. Refer to the caster adjustment for 500 thru 9000 Series.

ALL SERIES — 500 THRU 9000

Camber

Camber can be adjusted by bending the front axle beam. Fig. 8 shows the tool installation for increasing the camber angle. Fig. 19 shows the tool installation for decreasing the camber angle.

In all cases, the bend should be made between the front spring pad and the spindle. Otherwise, the spring pads will be thrown out of parallel with each other.

When making camber adjustments with this type of tool, pull the bottom of the jack forward as the pressure is

applied, so that the tool hangs at about the same angle as the spindle bolt (caster angle). This will prevent fore and aft bends from occuring in the axle beam. **Use a combination of blocks or shims that holds the tool in the best position.**

Do not heat the axle to bend it. Pads should be used to prevent tool marks.

Caster

The caster angle is controlled by the angle of the front spring pads, and changes as the load on the front axle increases or as the springs sag. The spring pads must be parallel to each other. Any change in the caster angle results from a twisted axle or spring sag.

If the springs have sagged, the caster angle can be adjusted by replacing the springs or by installing tapered wedges between the springs and the spring pads. Use only one wedge per side. The wedges are available in different thicknesses. Position the thick edge of the wedge toward the rear of the vehicle to increase the caster, or toward the front to decrease the caster. **When installing wedges, be sure that the front spring tie bolts extend through the wedge and into the axle pilot hole.**

Toe

If the toe is incorrect, loosen the clamp bolts at each end of the spindle connecting rod tube. Rotate the tube until the correct toe is obtained, and torque the clamp bolts to 31-42 ft.-lb. Recheck the toe to make sure that no changes occurred when the bolts were tightened.

STEERING STOP ADJUSTMENTS — TWIN-I-BEAM VEHICLES

All Twin-I-Beam vehicles except F-250 (6200 and 6900 GVW with BX or disc brakes) and F-350 (with BX or disc brakes) have built in steering stops. These F-250 and F-350 vehicles have non-adjustable stops.

Changing tire sizes may necessitate plug substitution.

STEERING STOP ADJUSTMENTS — ALL EXCEPT TWIN-I-BEAM VEHICLES

To avoid tire and/or steering linkage damage, the steering stop adjustments should be checked periodically, and adjusted if necessary. There are two separate adjustments which should be performed depending on the type of steering on the vehicle.

SPINDLE ARM AND PITMAN ARM STOP ADJUSTMENTS

Fig. 10 shows the position of the front wheels when checking the stop adjustment angles shown in the specification charts at the end of this Part.

Manual, Integral or Semi-Integral Power Steering Gear Manual, Integral Power Steering Gear

The following spindle stop adjustment is the only one required:

1. Raise the front of the vehicle until the wheels clear the floor.
2. Set spindle stop bolts to obtain specified angle.

Linkage Type Power Steering

1. Raise both front wheels off the ground by jacking under the axle.
2. Screw both Pitman arm stop bolts (Fig. 11) away from the Pitman arm to prevent contact with the Pitman arm prior to the spindle stops contacting the axle.
3. Start the engine and adjust each spindle stop to obtain the specified turn angle.
4. When the wheel is at each stop, screw the Pitman arm stop bolt in to contact the Pitman arm.
5. Return the wheels to straight ahead position, then turn each Pitman arm stop bolt two turns toward the Pitman arm. Tighten each Pitman arm stop bolt lock nut.

FRONT END GENERAL INSPECTION

ALL EXCEPT F-100 4-WHEEL DRIVE AND BRONCO

Do not check and adjust front wheel alignment without first making the following inspection for front end maladjustments, damage or wear.

1. Check the air pressure in all the tires. Make sure that the pressures agree with those specified for the tires and vehicles model being checked.
2. Raise the front of the vehicle off the floor. Grasp each front tire at the front and rear, and push the wheel inward and outward. If any free play is noticed between the brake drum and the brake carrier plate, adjust the wheel bearings. Replace the bearings if they are worn or damaged. Adjust and/or replace worn or damaged bearings as outlined in Group 11.
3. Grasp each tire at the top and bottom, and shake the wheel while watching the movement of the brake carrier plate. If the brake backing plate moves more than 1/32 inch at the outer edge or the spindle pin is loose in the I-Beam, rebush the spindles as outlined in the Front Suspension Part of this Manual.
4. Check all steering linkage for wear or maladjustment. Adjust and/or replace worn plates as outlined in Group 13.
5. Check the steering gear mounting bolts, and torque them wherever required. Check the front spring clips (U-bolts) and the spring tie bolt, and tighten them if necessary.
6. Spin each front wheel with a wheel spinner, and check and balance each wheel as required.
7. Rotate each front wheel slowly, and observe the amount of lateral or side runout. If the wheel runout exceeds 1/8 inch, replace the wheel or install the wheel on the rear. On a vehicle with cast wheels, runout can usually be corrected by loosening the rim clamp nuts and retightening them alternately and evenly. Then torque the nuts to specifications.

F-100 4-WHEEL DRIVE AND BRONCO

The following front end general inspection should be performed before adjusting toe-in or if steering or handling difficulties and/or excessive tire wear are encountered.

1. Check the air pressure in all the tires. Make sure that the pressures agree with those specified for the tires used.
2. Raise the front of the vehicle off the floor. Grasp each front tire at the front and rear, and push the wheel inward and outward. If any free play is noticed between the brake drum and the brake backing plate, adjust the wheel bearings. Replace the bearings if they are worn or damaged. Adjust and/or replace worn or damaged bearings as outlined in Group 11.
3. Check all steering linkage for wear or maladjustment. Adjust and/or replace worn parts as outlined in Group 13.
4. Check the torque on the steering gear mounting bolts and tighten if required.
5. Rotate each front wheel and tire slowly, and observe the amount of lateral or side runout. If the wheel and tire runout exceeds .080 inch, deflate the tire and rotate the tire on the wheel approximately 90 degrees. Thoroughly soap the wheel rim and reinflate the tire to the specified pressure for the respective tire size used. Recheck radial and lateral runout.

6. Inspect the radius arm to be sure they are not bent or damaged. Inspect the bushings at the radius arm to frame and radius arm to axle attachments for wear or looseness. Repair or replace parts as necessary.

① Manual or Power Steering

The caster specifications shown are with the frame level from front to rear. Measure front to rear frame angle when checking alignment and compensate as follows. If the front of the frame is lower than the rear, the actual caster angle is obtained by adding the frame angle to the caster angle shown on the checking equipment. If the front of the frame is higher than the rear, subtract the frame angle from the caster angle shown on the checking equipment.

The radius of both front tires must be equal within 1/8 inch. Radius to be checked from center line of spindle to the ground.

② Not adjustable.

F-600 (4 x 4)	7500 Manual or Power	+2-1/2	+3-1/2	+2-3/4	+3-3/4

① The caster specifications shown are with the frame level from front to rear. Measure front to rear frame angle when checking alignment and compensate as follows.
If the front of the frame is lower than the rear, the actual caster angle is obtained by adding the frame angle to the caster angle shown on the checking equipment.
If the front of the frame is higher than the rear, subtract the frame angle from the caster angle shown on the checking equipment.

PART 14-20 Front Suspension — Solid I - Beam

Does Not Apply To Twin I-Beam, 4-Wheel Drive Vehicles

COMPONENT INDEX	Page	COMPONENT INDEX	Page

FRONT SPRING SHACKLE AND BUSHING			
Installation	20-07		

DESCRIPTION

FRONT SUSPENSION

Semi-elliptic, leaf-type front springs are used on all vehicles. The springs are mounted to the frame side members, and are held in place on the axles by spring clips (U-bolts).

The front and rear ends of the springs are mounted on the frame side rails by either a locking bracket, a slipper type pad, a shackle, or a supporting bracket and rebound pin.

FRONT AXLE

The front axles are of the I-beam type with the front wheel spindles attached to the ends of the axles.

Each spindle is held in place on the axle by a spindle bolt. On models with 4000, 5000, and 5500-lb axles (except 500-900 units which use steel backed bronze bushings), Delrin bushings are pressed into the upper and lower ends of the spindle to provide bearing surfaces for the spindle bolt. A thrust bearing is installed between the lower end of the axle and the spindle to support the load on the axle. A spindle arm, to which the steering linkage is attached, is installed on each spindle.

FRONT SHOCK ABSORBER

The hydraulic shock absorbers are of the direct, double-acting type. They provide a continuous damping effect both on compression and rebound. These shock absorbers are of telescopic design with rubber grommets at the mounting points for quiet operation. Since the shock absorbers are sealed, non-adjustable units, they must be replaced as complete assemblies.

REMOVAL AND INSTALLATION

FRONT SPRING

P-SERIES

Removal and Installation

1. Raise the vehicle frame until the weight is off the front springs with the wheels still touching the floor. See Group 50 for hoisting instructions.
2. Remove the spring clips (U-bolts and nuts) and the spring clip plate (Fig. 1).
3. Remove the nut from the spring to frame bracket bolt and drive the bolt out of the spring and bracket with a drift.
4. Remove the nut from the lower shackle bolt, and drive the bolt out of the spring and shackle bars.
5. Remove the grease fittings from the shackle bolts.
6. Remove the spring, noting the position of any caster wedges.
7. If required, install new bushings in the spring and shackle bracket.
8. Install the caster wedges if so equipped. Position the wedges with the thick edges in the same direction as they were before removal. Install the spring on the spring seat.
9. Position the spring eye between the shackle bars, and install the lower shackle bolt and nut (Fig. 1). Do not torque.
10. Position the spring eye in the bracket and install the bolt through the bracket and spring, with the bolt head toward the outside of the

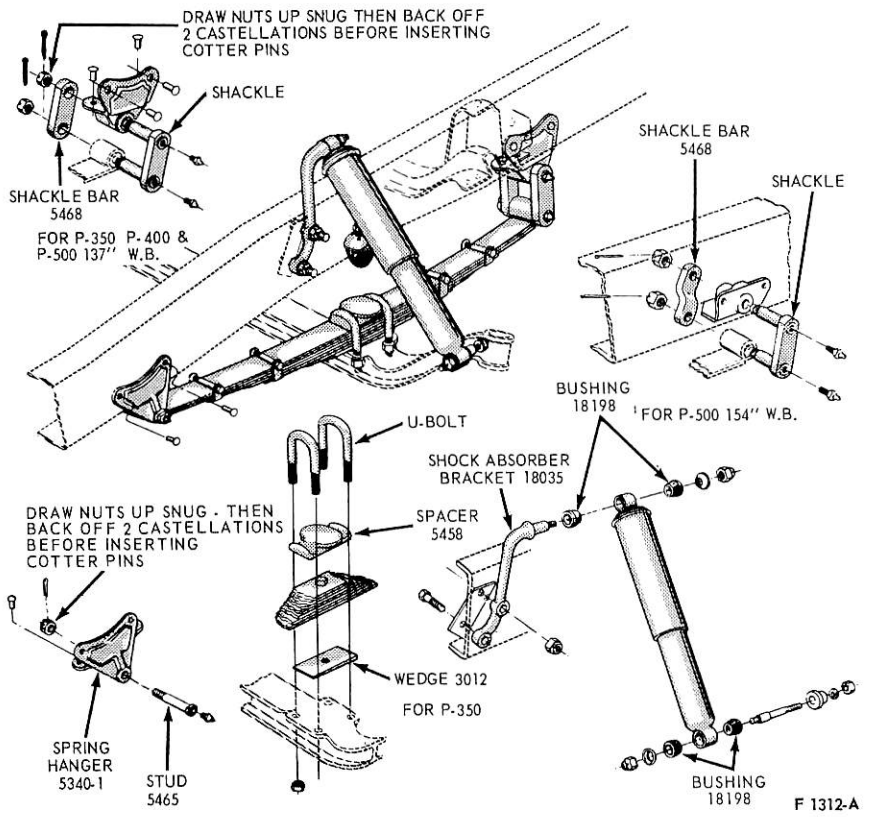

FIG. 1 Standard Front Spring—P-Series (Optional Similar)

vehicle. Install but do not torque the nuts.

11. Install the grease fittings in the shackle bolts.
12. Place the spring clips in position over the spring clip plate and through the holes in the axle. Make sure that the spring tie bolt is centered in the recess in the axle.
13. Install the spring clip nuts and lower the vehicle to the floor.
14. Torque the lower shackle nut, spring bracket nut, and spring clip nuts to specifications in that order.

LN-500-750 SERIES

Removal and Installation

1. Raise the vehicle frame until the weight is off the front springs, with the wheels still touching the floor. Remove the shock absorber.
2. Remove the cotter pin from the support bracket stud and remove the stud from the front bracket.
3. Remove the cotter pin and nut from the rear bracket shackle pin and drive out the pin (Fig. 2).
4. Remove the nuts from the 2 spring clips (U-bolts) which hold the spring on the axle (Fig. 2). Remove the spring, noting the position of any caster wedges.

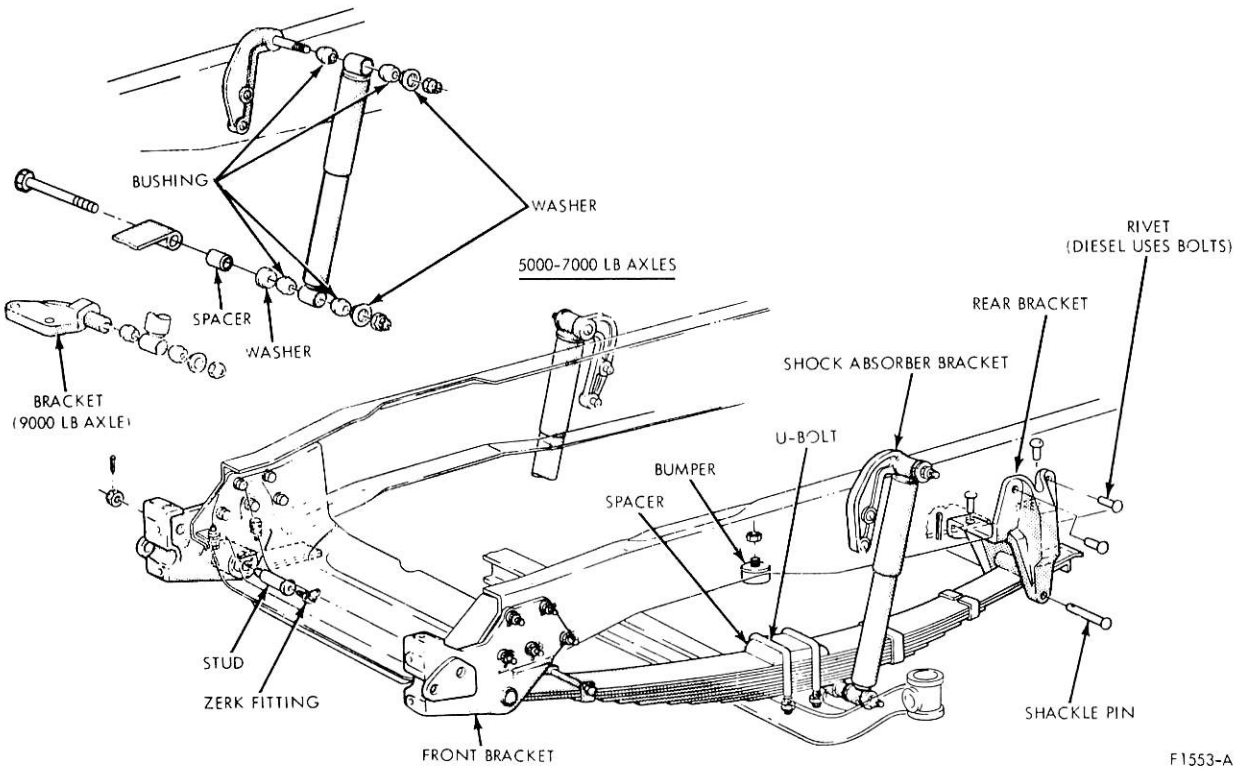

FIG. 2 Front Spring—LN-500-750, 6000-7000

5. Position the spring on the spring seat and align the spring eye with the front spring bracket (Fig. 2).
6. Prior to installation, coat the bushing with C1AZ-19590-B lube. Drive the stud through the bracket and the eye of the spring. The lubrication opening in the stud should face inward.
7. Install the attaching nut.
8. Tighten the nut to 31-42 ft-lb, then back it off two castellations. Install a new cotter pin.
9. Install the lubrication fitting.
10. Raise the opposite end of the spring leaf into the supporting bracket, then install the pin in the bracket. Secure the pin with a cotter pin.
11. On a vehicle with axle caster wedges, place the wedges between the axle and the spring, with the thick edges positioned the same as they were originally. Place the spring clips in position over the spring clip plate and through the holes in the axle. Make sure that the spring tie bolt is centered in the recess of the axle.
12. Install the nuts on the spring clips. Lower the vehicle to the floor and torque the spring clip nuts to specifications. Lubricate front shackle pin.

F-B-500-750 SERIES

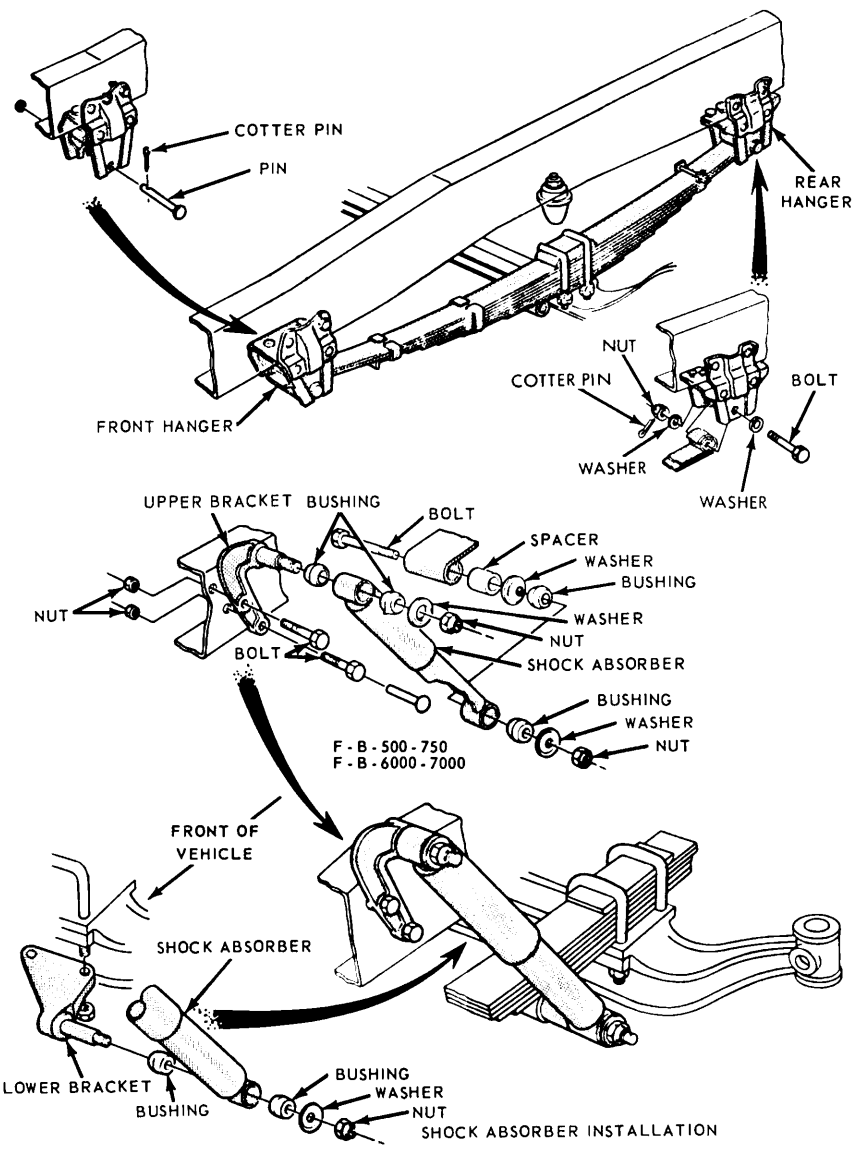
Removal and Installation

1. Raise the vehicle frame just enough to remove the weight from the front spring while the front wheel still contacts the floor.
2. Support the front axle to remove the weight from the spring U-bolts.
3. Remove the four U-bolt nuts and the two U-bolts (Fig. 3).
4. Remove the cotter pin, nut, washers and bolt that secure the spring to the rear hanger.
5. Remove the cotter pin from the front spring hanger pin and remove the pin.
6. Lift the spring from the axle and front hanger.
7. Position the spring in the front hanger and on the axle.
8. Install the front spring hanger pin and cotter pin.
9. Position the axle so that the spring through-bolt enters the locating hole in the axle.
10. Install the two U-bolts making sure that the front one enters the shock absorber lower bracket. Install the nuts. Torque to specification.
11. Raise or lower the axle as required to align the spring eye with the bolt hole in the rear bracket. Install the bolt, washers and nut making sure the one washer is between the nut and bracket and one between the bolt head and bracket. With the weight of the vehicle on the springs, torque the rear hanger bolt nut to specification and advance to the next castellation if necessary to install cotter pin.
12. Lower the vehicle and remove the jacks.

L-LT-LN-LNT-800-900, 8000-9000, C-CT AND W-SERIES

Removal and Installation

1. Raise the vehicle until the weight is off the front springs, with the wheels still touching the floor. Remove the shock absorber, if so equipped.
2. Remove the bolt that secures the spring retaining pin in the front bracket (Figs. 4, 5 and 6).
3. Remove the retaining pin from the front bracket.
4. Remove the four through bolts and then the two shackle pins securing the shackle assembly. Remove the shackle from the spring and rear bracket.
5. Remove the two U-bolts that attach the spring to the axle.
6. Lift the spring from the axle being careful not to lose the wedges or spacer.
7. Position the spring on the spring seat and align the spring front eye with the spring bracket (Figs. 4, 5 and 6).
8. Remove the lubrication fitting from the retaining pin. Position the pin so that the notches are aligned with the attaching bolt holes in the front bracket, and the lubricator opening facing outward. Drive the pin through the bracket and spring, then



F-750 & F-7000 (CAT. ENG.) W 9000 LB. AXLE F1471-B

FIG. 3 Front Spring Installation—F-B-500-750

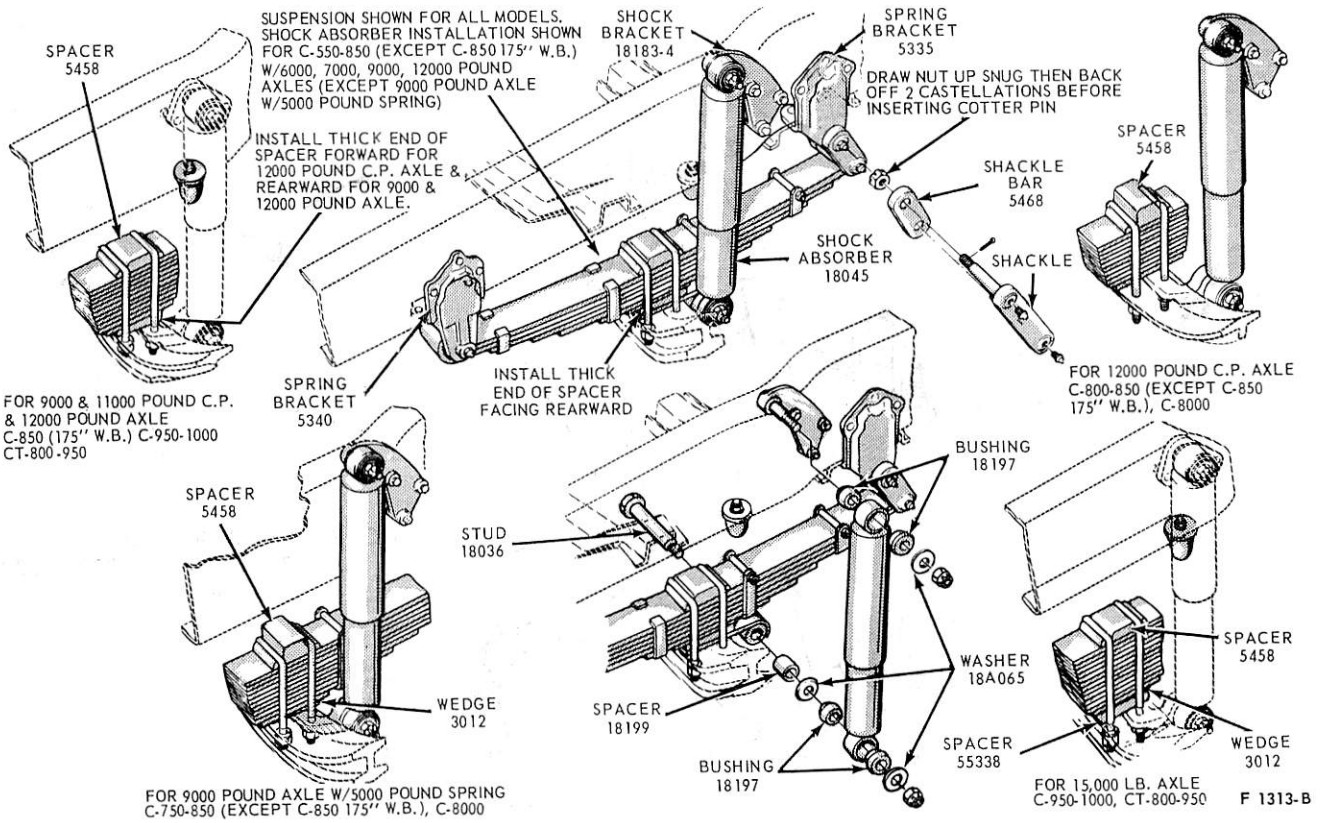


FIG. 4 Front Spring—C-Series

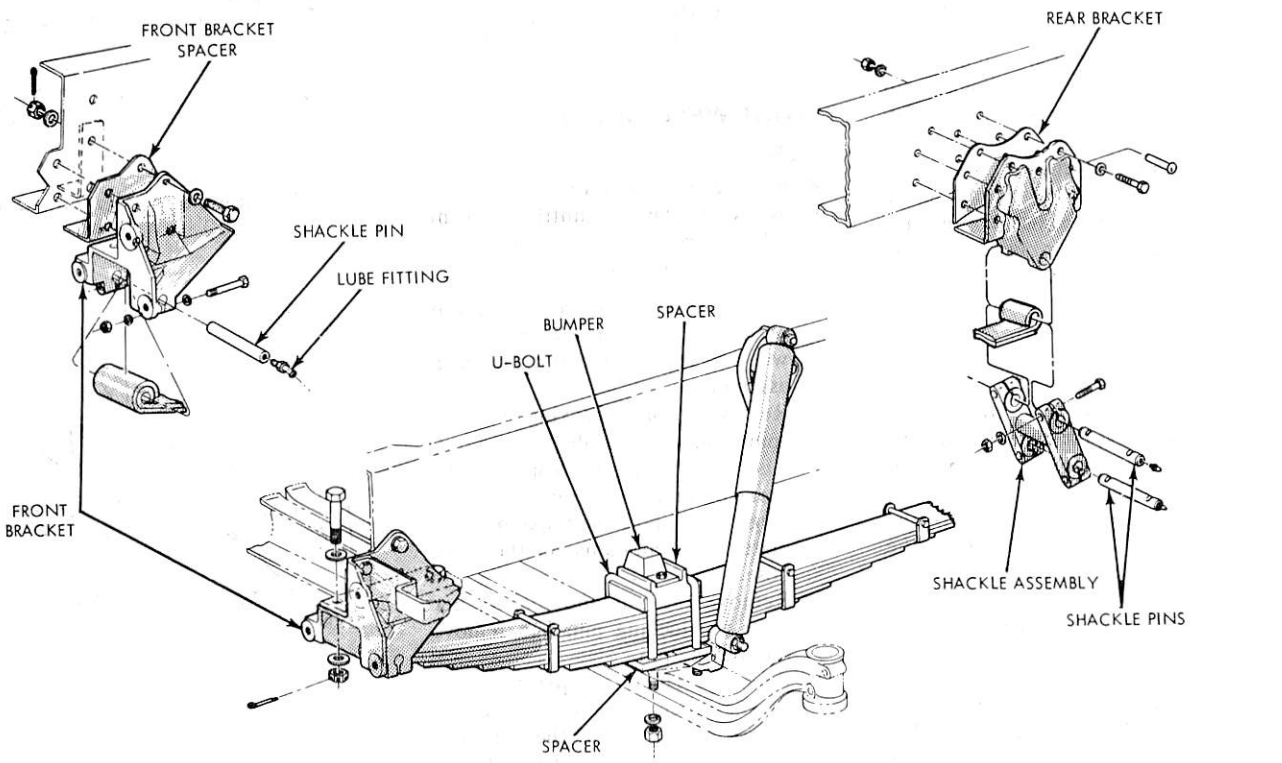

FIG. 5 Front Spring—L-LT-LN-LNT-800-900, 8000-9000

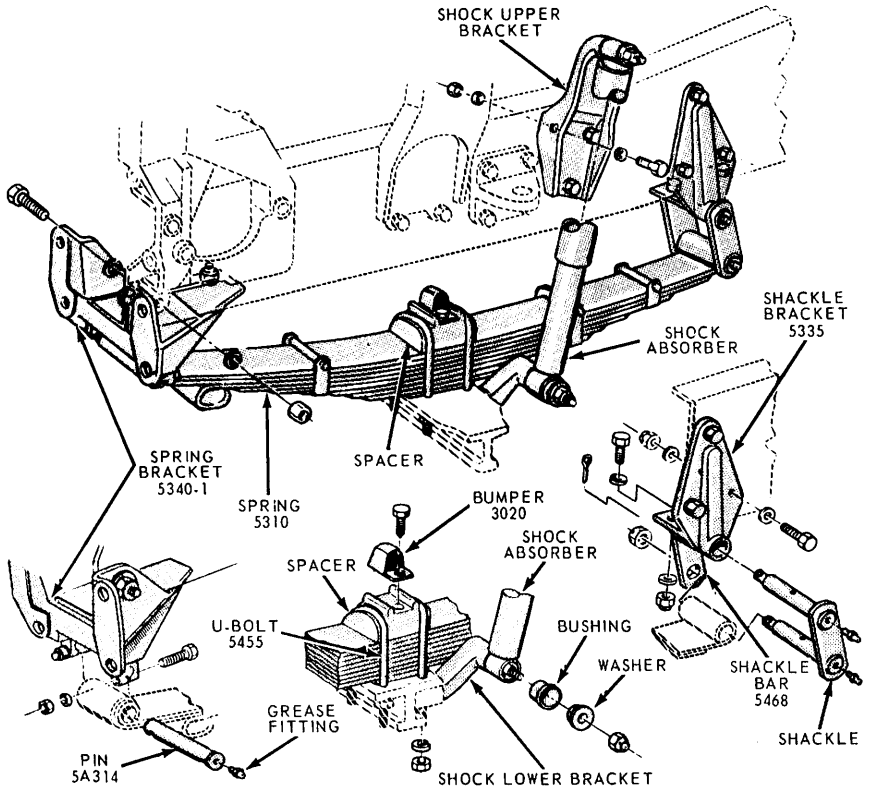

FIG. 6 Front Spring—W-Series

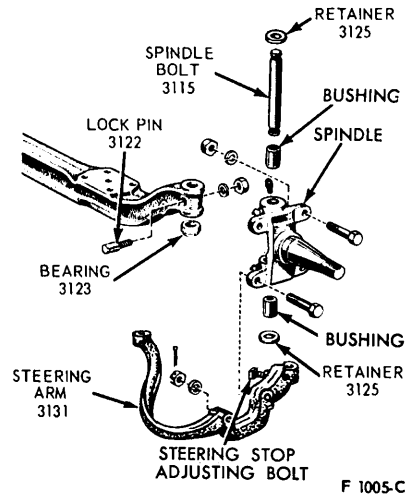

FIG. 7 Spindle Installation—P-350-3500-400-4000 (P-500-500 Similar)

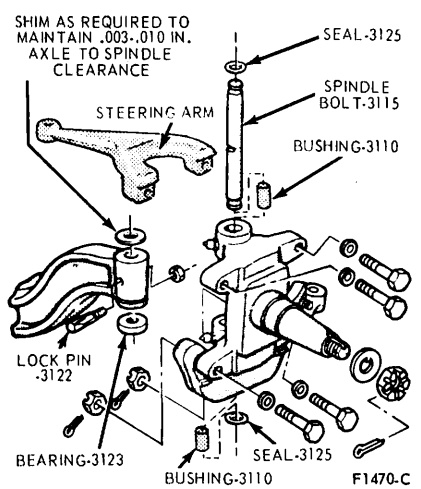

FIG. 8 Spindle Installation—5000-5500 Lb Axles

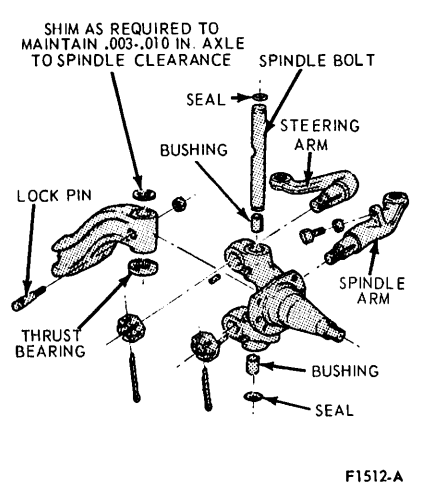

FIG. 9 Spindle Installation—6000-7000 Lb Axles—Except C-Series

install the attaching bolts, lockwashers, and nuts. Install the lubrication fitting in the pin.

9. Raise or lower the rear end of spring as required to insert the shackle into the spring eye and rear bracket. Tap on the shackle until it bottoms in the spring and bracket.
10. Position the shackle assembly so the notches on the shackle pins are aligned with the through bolts. The lubricating openings face outward. Install the through bolt nuts and torque to 31-42 ft-lb.
11. On vehicles equipped with a spacer, place it on the axle.
12. On vehicles equipped with a caster wedge, place it on the axle with the thick edge in the same position as it was originally.
13. Position the spring clips over the spring clip plate and through the holes in the axle. Make sure the spring tie bolt is centered in the recess of the axle, spacer or caster wedge.
14. Install the shock absorber lower bracket to the underside of the axle (except as shown in Fig. 4) so that the spring clip (U-bolt) ends enter the holes in the bracket. Install the flat washers and lock nuts on the spring clips.
15. Lower the vehicle to the floor and torque the spring clip nuts to specification. Lubricate the shackle bolts.

FRONT WHEEL SPINDLE

P-SERIES

Removal and Installation

1. Raise the vehicle until the front wheel clears the floor and place a support under the axle.
2. Back off the brake adjustment if necessary, and remove the wheel, wheel bearing, hub and drum as an assembly.
3. Remove the brake backing plate and spindle arm-to-spindle bolt and nut. Remove the spindle arm and the brake backing plate from the spindle (Fig. 7). Support the brake backing plate to prevent damaging the brake hose.
4. Remove the nut and lockwasher from the locking pin, and remove the locking pin.
5. Remove the top spindle bolt retainer; then, drive the spindle bolt out from the top of the axle and remove the spindle and bearing (Fig. 7).
6. Make sure the spindle bolt hole in the axle is free of nicks, burrs or

foreign material. Coat the spindle bolt bushings and the spindle bolt hole in the axle with oil, and place the spindle in position on the axle.

7. Pack the spindle bolt bearing with chassis lubricant and insert the spindle bolt bearing between the bottom of the axle and the spindle with the open end of the bearing seal facing downward.
8. Install a new retainer at the top of the spindle bolt, and install the spindle bolt in the spindle with the locking pin notch in the spindle bolt lined up with the locking pin hole in the axle. Drive the spindle bolt through the axle until the spindle bolt retainer is seated against the spindle.
9. Install a new locking pin after making sure the notch in the spindle bolt is lined up with the locking pin hole in the axle. Install the locking pin lockwasher and nut, and torque the nut to specification. Install a new retainer at the bottom of the spindle bolt.
10. Install the brake backing plate and spindle arm. Torque the brake backing plate and spindle arm-to-spindle bolt and nut to specification, and advance the castellated nut as required for installation of the cotter pin.
11. Install the wheel, hub and drum assembly, and adjust the wheel bearing as outlined in Part 11-02.
12. Lubricate the spindle bolt.
13. Check and, if necessary, adjust toe-in.

MEDIUM, HEAVY AND EXTRA HEAVY TRUCKS

Removal and Installation

1. Loosen the front wheel hub bolt nuts. Raise the front of the vehicle and remove the wheel.
2. Remove the hub and drum and the wheel bearing from the spindle.
3. If the brake backing plate is bolted to the spindle, remove the plate from the spindle. To prevent damage to the brake hose, hang the backing plate from the frame.
4. Disconnect the spindle arms from the spindle.
5. On all 5000, 5500, 6000 and 7000 lb axles (the latter two not including C-Series), remove the seal (O-ring) from the top of the spindle bolt, remove the nut from the spindle bolt lock pin (Figs. 8 and 9) and drive the lock pin out of the axle. Drive the spindle bolt out from the top of the axle with a suitable drift (Fig. 10).

On 9000, 12000 (Center Point), 12000, 16000, 18000 and 20000 lb axles, three separate spindle top mountings are used. Vehicles equipped with cambrakes and either a 9000 or 12000 lb axle utilizes a three-bolt cap/zerk fitting with a gasket (Fig. 11). Hydraulic or wedge brake units with 9000 or 12000 lb axles have a combination brake hose fitting/zerk cap (Fig. 11). The 12000 (Center Point), 16000, 18000 and 20000 lb axles have a brake hose fitting cap without the zerk (an extra zerk fitting is mounted on the upper part of the spindle on these axles). See Fig. 11. After removing the appropriate cap and gasket, remove the snap ring and expansion plug from the bottom of the spindle bolt. A spacer is also present only on vehicles with 12000 lb axles immediately below the bushing. Drive out the staked lock pins with a suitable tool; then, drive out the spindle from the top of the axle (Fig. 10).

On 15000 lb axles, remove the dust seal cap, gasket and spacer from the top of the spindle. Remove the retainer and expansion plug from the bottom of the spindle (Fig. 12). Remove the cotter pin and spindle bolt retaining nut. Drive out the tapered spindle bolt from the top of the axle (Fig. 10).

6. Remove the spindle assembly from the axle.
7. To assemble, place the spindle in position on the axle. Insert the spindle bolt thrust bearing between the bottom of the axle and the spindle. Pack the thrust bearing and coat all mating surfaces of spindle and axle parts with M1C75-B lubricant prior to assembly. **On all axles, the thrust bearing must be installed with the retainer lip facing down.** The shim (or shims) is placed between the top of the axle and the spindle. A .003-.010 axle-to-spindle clearance must be maintained on all axles.

On 5000 and 5500 lb axles, line up the notch in the spindle with the spindle bolt locking pin hole in the axle (Fig. 8). The spindle bolt must be installed with the end marked T facing upward. Drive the spindle bolt through the axle until the notch and hole are in line. Fasten the spindle bolt in place by installing a new locking pin from either side of the I-Beam; then, install the nut on the lock

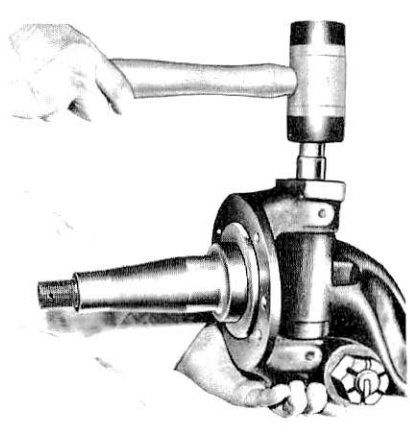

FIG. 10 Removing Spindle Bolt—Typical

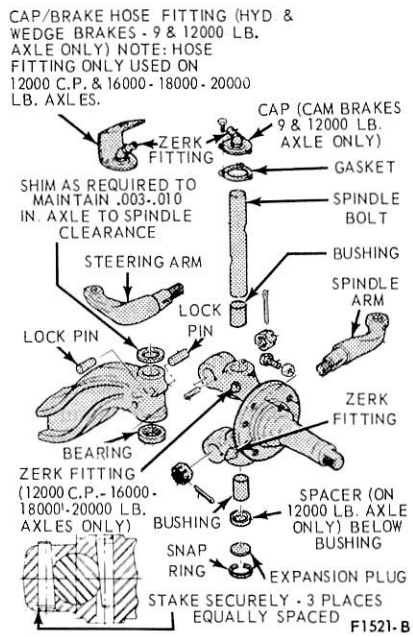

FIG. 11 Spindle Installation—9000,12000 (Center Point), 12000,16000,18000 and 20000 Lb Axles

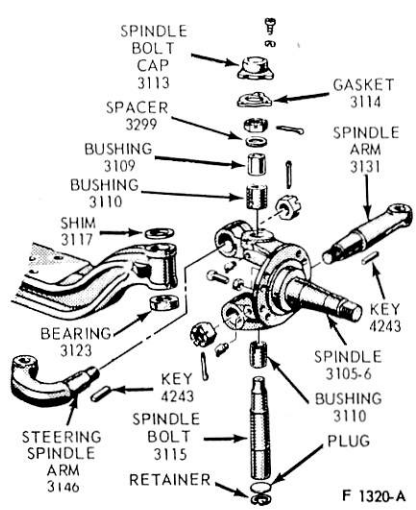

FIG. 12 Spindle Installation—15000 Lb Axle

pin. Install a new seal (O-ring) in the groove at each end of the spindle bolt.

On 6000 and 7000 lb axles, line up the notch in the spindle bolt with the spindle lock pin hole in the axle (Fig. 9). The spindle bolt must be installed with the end marked T facing upward. Drive the spindle bolt through the axle until the notch and hole are in line. Fasten the spindle bolt in place by installing a new lock pin from either side of the I-Beam; then, install the nut on the lock pin. Install a new seal (O-ring) in the groove at each end of the spindle bolt.

On 9000, 12000 (Center Point), 12000, 16000, 18000 and 20000 lb axles, line up the notches in the spindle bolt with the spindle lock pin holes in the axle (Fig. 11). Drive the spindle bolt through the axle until the notches and holes are in line. This spindle design uses two non-threaded spindle lock pins per spindle bolt. On the 9000 lb axle, the upper and lower pins are the same size while all other axles use a short pin in the upper hole and a longer pin in the lower hole. These pins are available with three different length flats. Select the pins that, when inserted, result in the round ends being below the axle surface a maximum of approximately 1/8 inch. All pins must be installed from opposite sides of the axle and secured by prick punching the edge of the hole in three equally spaced places. Install a new expansion plug and lock ring. Install the gasket and upper cap.

On 15000 lb axles, the tapered spindle bolt must be installed from the underside of the spindle. Install a new spacer and bushing at the top of the spindle upper bushing (Fig. 12). Install the spindle retaining nut and cotter pin; then, install a new expansion plug and snap ring at the bottom of the spindle and the dust seal cap and gasket at the top.

8. Install the brake backing plate on the spindle. On 5000-5500 lb axles, make certain hardened flat washers of the same type are installed between the backing plate and the attaching bolt heads (Fig. 8). On 6000 lb and larger axles, install the spindle arms before installing the brake backing plate.
9. Lubricate the spindle bushings until lubricant is visible at the spindle-to-axle area.
10. Install the hub and drum assembly and the wheel. Adjust the wheel bearings as outlined in Part 11-02.
11. Check and adjust the toe-in.

FRONT SHOCK ABSORBER

Removal and Installation

To replace the front shock absorber, remove the selflocking nut, steel washer, and rubber bushings at the upper and lower ends of the shock absorber. Remove the shock absorber.

When installing a new shock absorber, use new rubber bushings. Position the shock absorber on the mounting brackets with the large diameter at the top.

Install the rubber bushing, steel washer, and self-locking nut. Tighten the nut until it rests against the shoulder of the stud. Torque to specification.

FRONT SPRING SHACKLE AND BUSHING

W-SERIES

Installation

When replacing front spring bushings on subject vehicles (three required each side; both front and rear spring eyes and rear shackle bracket), the following steps must be performed:

1. Ream all bushings to 1.005 inch after eye and bracket installation (Fig. 13).
2. Install a new shackle assembly.
3. Torque the shackle pin retaining nuts to 30-40 ft-lb.
4. Install a new front spring pin.
5. Make certain the lubrication fittings are properly installed. Lubricate with C1AZ-19590-B lubricant.

SPINDLE BUSHING

Removal and Installation

1. On a spindle with bronze bushings, drive the bushing out of the spindle (Fig. 14) with a tool that is slightly smaller than the spindle bore. If a tool is not available, carefully drive a small center punch between the bushing and the spindle, at the split side of the bushing. Collapse the bushing, and remove it from the spindle bore.
2. Clean the spindle bores thoroughly, and make certain that the lubricating holes are not plugged.
3. Position a new bushing in the spindle bore with the lubricating hole in line with the lubricating fitting and the open end of the oil groove toward the axle. Drive a bronze bushing into the spindle (Fig. 15) with a driver that pilots in the bushing. It is not necessary to drive a Delrin bushing into place.

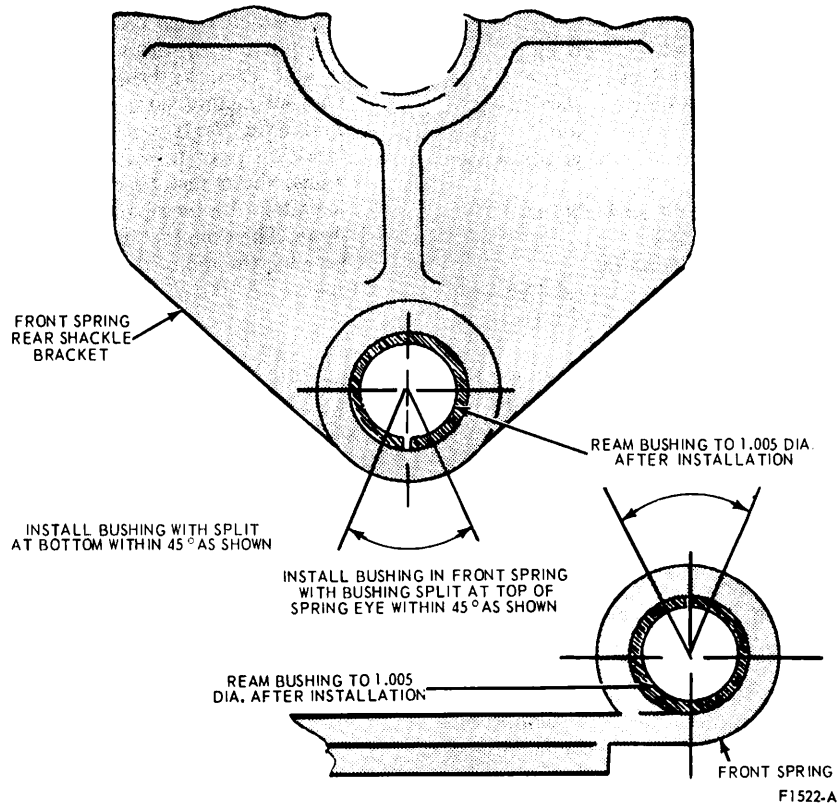

FIG. 13 Front Spring Bushing Installation

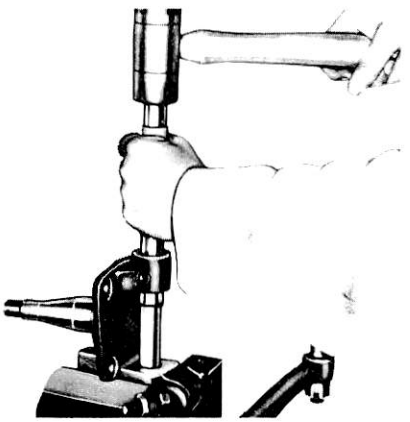
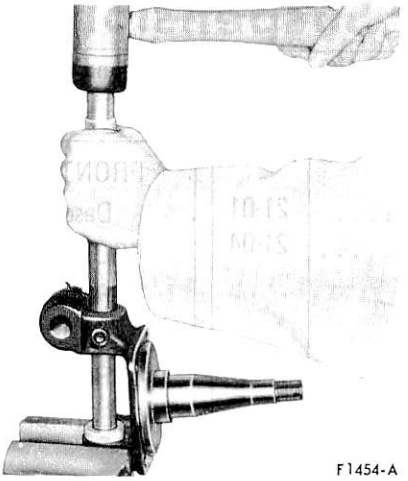


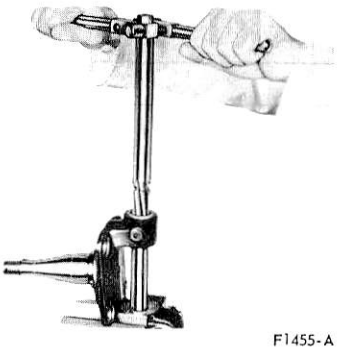
F1453-A

FIG. 14 Removing Bronze Bushing



F1454-A

FIG. 15 Installing Bronze Bushing



F1455-A

FIG. 16 Reaming Bronze Bushing

4. Install the remaining bushing in the same manner.
5. Bronze bushings should be reamed .001 to .003 inch larger than the diameter of a new spindle bolt (Fig. 16). **Do not ream Delrin bushings.**
6. Clean all the metal shavings from bronze bushings after reaming, and coat the bushing and pin with lubricant prior to assembly.

When a front or rear spring bushing is replaced on vehicles with steel backed bronze bushings, the split in the bushing must be installed directly opposite to the loaded side of the spring.

The bushing should be reamed .005 to .012 inch larger than the diameter of a new spring pin. After reaming, clean and coat the bushing and pin with C1AZ-19590-B lubricant prior to assembly.

DESCRIPTION

FRONT SUSPENSION

The F-100, 250, 350 and Econoline vehicles use coil springs with the two I-beam type front axles. The springs are mounted between the frame spring pocket and the axle (Fig. 1).

FRONT AXLE

The F-100, 250, 350 (4 x 2) and Econoline vehicles use two I-beam type front axles (one for each front wheel). One end of each axle is attached to the spindle and a radius arm and the other end is attached to a frame pivot bracket on the opposite side of the vehicle (Fig. 1).

Each spindle is held in place on the axle by a spindle bolt which pivots in either Delrin or bronze bushings pressed in the upper and lower ends of the

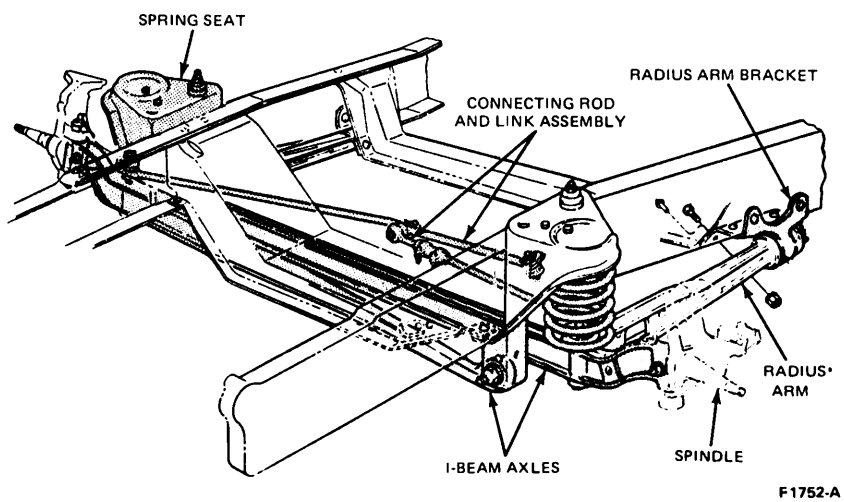

FIG. 1 Front Suspension F-100, 250, 350 (Econoline Similar)

spindle. A thrust bearing is installed between the lower end of the axle and the spindle to support the load on the axle. On E-100-200, the spindle arm is bolted on each spindle for attachment to the steering linkage. See Figure 3. The other vehicles have a spindle arm which is an integral part of the spindle (Figs. 4 and 5).

FRONT SHOCK ABSORBER

The hydraulic shock absorbers are of the direct, double-acting type. They provide a continuous damping effect both on compression and rebound. These shock absorbers are of telescopic design with rubber grommets at the mounting points for quiet operation. Since the shock absorbers are sealed, non-adjustable units, they must be replaced as complete assemblies.

REMOVAL AND INSTALLATION

FRONT SPRING

F-100-250-350

Removal and Installation

1. Raise the front of the vehicle and place safety stands under the frame and a jack under the axle. See Group 50 for hoisting instructions.
2. Disconnect the shock absorber from the lower bracket.
3. Remove one bolt and nut and remove the rebound bracket (Fig. 7).
4. Remove two spring upper retainer attaching bolts from the top of the spring upper seat and remove the retainer. On F-350 models, remove the bolts retaining the upper spring clip to the upper spring seat and remove the clip.
5. Remove the nut attaching the spring lower retainer to the lower seat and axle and remove the retainer.
6. Lower the axle and remove the spring.
7. Place the spring in position and raise the front axle.
8. Position the spring lower retainer over the stud and lower seat, and install the attaching nut.
9. Position the upper retainer over the spring coil and against the spring upper seat, and install the 2 attaching bolts.
10. Torque the upper retainer attaching bolts and lower retainer attaching nut to specification.
11. Connect the shock absorber to the lower bracket and install the rebound bracket.
12. Remove the jack and safety stands.

ECONOLINE

Removal and Installation

1. Remove the floor mat retainer from the lower end of the door opening. Fold the mat to one side to gain access to the shock absorber cover plate (Fig. 2).
2. Remove the two cover plate attaching screws and remove the plate.

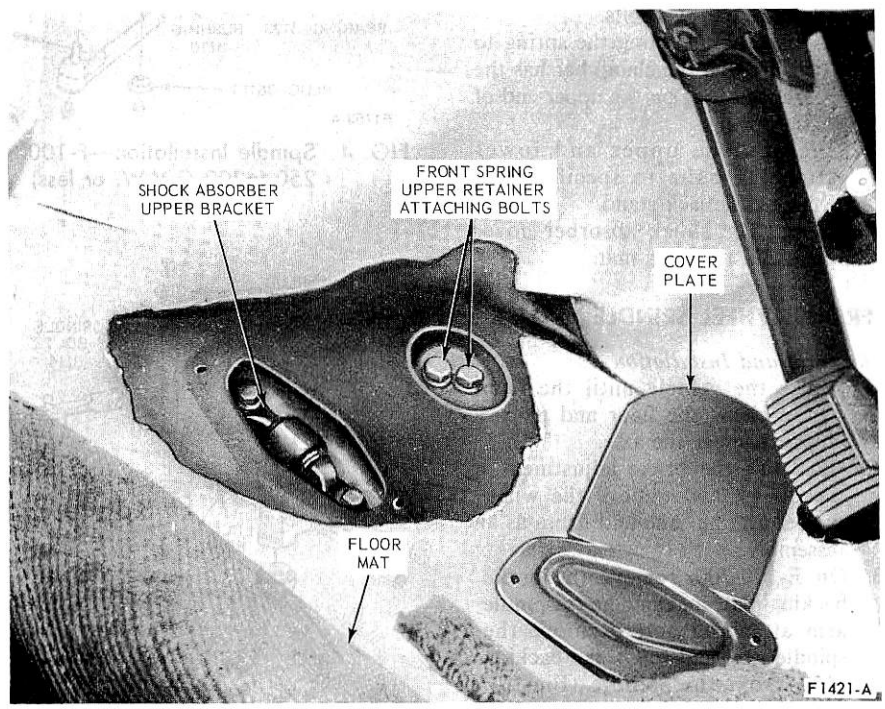

FIG. 2 Shock Absorber And Front Spring Cover Plate

3. Remove the two spring upper retainer attaching screws and remove the retainer insulator and clamp (Fig. 1).
4. Support the frame side rails with a jack stand.
5. Place a jack under the axle, then remove the spring lower retainer attaching bolt. Remove the spring support and lower retainer.
6. Lower the jack slowly to relieve the spring tension, then remove the spring.
7. Position the spring on the axle with the pigtails toward the rear (Fig. 1).
8. Position the spring lower support and retainer and install the attaching bolt loosely.
9. Position the upper insulator on the spring.
10. Raise the jack high enough to apply a light tension on the spring.
11. Install the spring upper retainer and

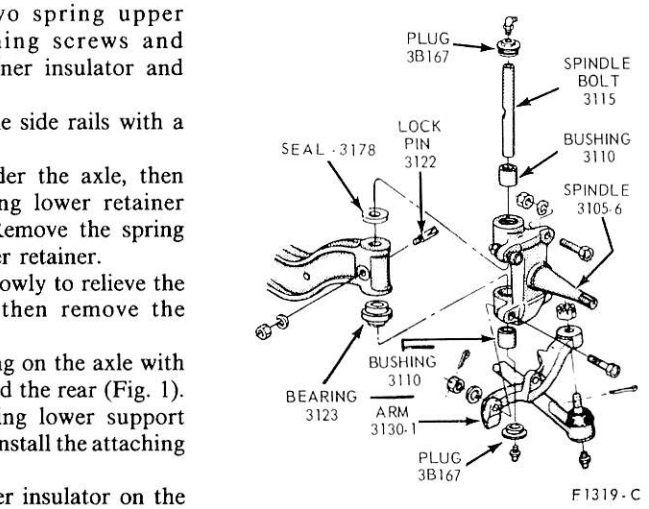

FIG. 3 Spindle Installation—E-100, E-200

the clamp in the following manner by:

a. Checking the retainer assembly to insure the bolts are approximately flush with the bottom of the clamp bar.
b. Inserting the retainer assembly into the hole in the floor with the clamp bar pointing toward the right side of the vehicle.
c. Rotating the retainer assembly approximately 90 degrees clockwise until the oval retainer seats properly to the oval hole and secure the two bolts.
d. Visually inspecting the spring to insure that the clamp bar has the trapped tang on the upper end of the spring.

12. Tighten the upper and lower attaching bolts to specification. Remove the jack stand.
13. Install the shock absorber cover plate and the floor mat.

FRONT WHEEL SPINDLE

Removal and Installation

1. Raise the vehicle until the front wheel clears the floor and place a support under the axle.
2. Back off the brake adjustment if necessary, and remove the wheel, wheel bearing, hub and drum as an assembly.
3. On E-100-200, remove the brake backing plate and spindle-to-spindle arm attaching bolt. Remove the spindle arm and the brake backing plate from the spindle (Fig. 3). Support the brake backing plate hose.
4. On F-100-250 (6200 GVW or less), remove the caliper key retaining screw. Use a brass rod and a light hammer to drive out the caliper support key and caliper support spring. It is not necessary to disconnect the hydraulic line to the caliper. Remove the caliper from the spindle by pushing the caliper downward against the spindle assembly and rotating the upper end of the caliper upward and out of the spindle assembly. Wire the caliper to a suspension component making sure the weight of the caliper is not supported by the brake hose. The brake hose must not be stretched or twisted. Disconnect the steering linkage from the integral spindle and spindle arm (Fig. 4).
5. On F-250 (over 6200 GVW) -F-350 nd E-300, disconnect the steering linkage from the integral spindle and spindle arm (Fig. 5).

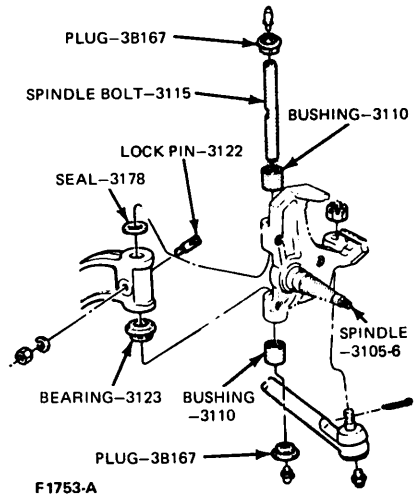

FIG. 4 Spindle Installation—F-100-250 (6200 G.V.W. or less)

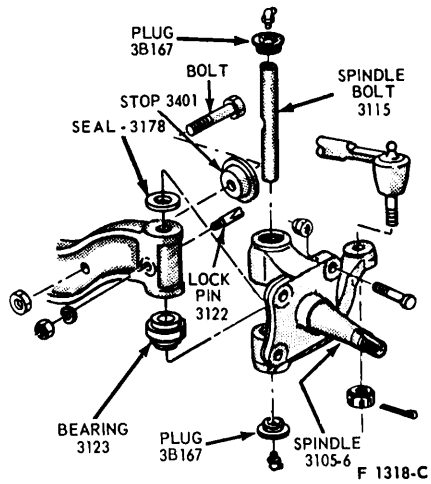

FIG. 5 Spindle Installation—F-250 (over 6200 G.V.W.) F-350, E-300

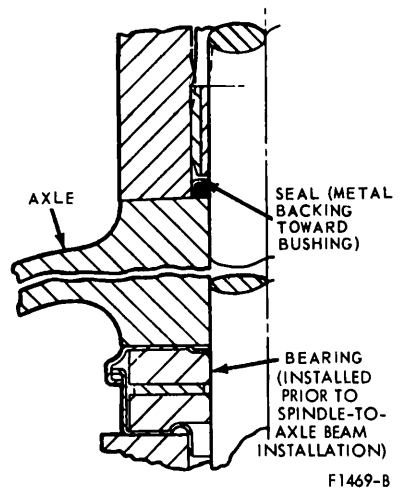

FIG. 6 Bearing Seal Installation

6. Remove the nut and lockwasher from the locking pin, and remove the locking pin.
7. Remove the upper and lower spindle bolt plugs; then, drive the spindle bolt out from the top of the axle and remove the spindle and bearing (Fig. 3). Knock out the seal.
8. Make sure the spindle bolt hole in the axle is free of nicks, burrs or foreign material. Install a new seal and coat the spindle bolt bushings and the spindle bolt hole in the axle with oil; then, place the spindle in position on the axle.
9. Pack the spindle thrust bearing with chassis lubricant and insert the bearing into the spindle with the open end (lip side) of the bearing seal facing downward into the spindle (Fig. 6).
10. Install the spindle pin in the spindle with the locking pin notch in the spindle bolt lined up with the locking pin hole in the axle. Drive the spindle bolt through the axle from the top side until the spindle bolt locking pin notch is lined up with the locking pin hole.
11. Install a new locking pin after making sure the notch in the spindle pin is lined up with the locking pin hole in the axle. Install the locking pin lockwasher and nut, and torque the nut to specification. Install the spindle bolt plugs at the top and bottom of the spindle bolt.
12. On E-100-200, install the brake backing plate and spindle arm. Torque the brake backing plate and spindle-to-spindle arm bolt and nut to specification (30-50 ft-lb). Advance the castellated nut as required for installation of the cotter pin.
13. On F-100-250 (6200 GVW or less), position the caliper on the spindle assembly about the spindle upper mounting surface. Be very careful when installing the caliper to prevent tearing or cutting the boot as it slips over the inner shoe. Use a brake adjusting tool or a screwdriver to hold the upper machined surface of the caliper against the surface of the spindle. Install the caliper support spring and caliper support key. Use a soft mallet to drive the key and spring assembly into position. Install the key retaining screw and tighten to 12-18 ft-lb. Connect the steering linkage to the spindle (all F-Series and E-300). Torque to specification (50-75 ft-lb) and advance the nut as required for installation of the cotter pin.

14. Install the wheel, hub and drum assembly, and adjust the wheel bearing as outlined in Part 11-02.
15. Lubricate the spindle assembly with ESA-M1C75B.
16. Check and, if necessary, adjust toe.

FRONT SHOCK ABSORBER

F-100-350 (4 X 2)

Removal and Installation

To replace the front shock absorber, remove the self-locking nut, steel washer, and rubber bushings at the upper end of the shock absorber. The lower end of the shock absorber is attached to a bracket (mounted on the radius arm) by a bolt and nut. Remove the shock absorber.

When installing a new shock absorber, use new rubber bushings. Position the shock absorber on the mounting brackets with the stud end at the top.

Install the rubber bushing, steel washer, and self-locking nut. Tighten the nut to torque specifications (15-25 ft-lb: upper end, 40-60 ft-lb: lower end).

ECONOLINE

Removal and Installation

1. Remove the bolt that attaches the lower end of the shock absorber to the radius arm bracket.
2. Remove the floor mat retainer from the lower end of the door opening. Fold the mat to one side to gain access to the shock absorber cover plate (Fig. 2).
3. Remove the two cover plate attaching screws and remove the plate.
4. Remove the two shock absorber bracket attaching bolts.
5. Lift the shock absorber and bracket up through the floor pan.
6. Position the shock absorber and install and tighten the two attaching bolts (Fig. 2) to specification.
7. Install the shock absorber cover plate.
8. Position the floor mat and install the retainer.
9. Connect the lower end of the shock absorber to the bracket and torque the bolt to specification.

FRONT AXLE

Removal and Installation

1. Raise the front of the vehicle until the front wheels are off the floor.
2. Remove the hub cap, hub and drum.
3. Remove the cotter pins from the spindle arm-to-spindle attaching nuts, and remove the nuts (except vehicles with integral spindle and spindle arm).
4. Remove the upper spindle to brake backing plate attaching nuts and remove the backing plate. Wire the backing plate to the under body to prevent damage to the brake hose.
5. Remove the upper and lower spindle plugs.
6. Remove the lock pin that retains the spindle bolt in the spindle.
7. Place a jack under the axle and remove the spindle bolt, spindle, and bearing from the axle.
8. Disconnect the shock absorber from the lower bracket.
9. Remove one nut and bolt and remove the rebound bracket.
10. Remove the nut attaching the spring lower retainer to the lower seat and axle and remove the retainer (Fig. 7). Then, lower the axle and remove the spring lower seat.
11. Disconnect the radius arm from the axle.
12. Remove the axle to frame pivot bracket attaching bolt and nut and remove the axle.
13. Position the axle to the frame pivot bracket and install the bolt and nut finger tight.
14. Position the radius arm to the axle and install the bolt, nut, and shim and torque to specification.
15. Position the spring lower seat over the bolt on the axle.
16. Raise the axle and position the spring to the lower seat.
17. Position the spring lower retainer over the bolt and lower seat, and install the attaching nut. Torque the nut to specification.
18. Connect the shock absorber to the radius arm bracket.
19. Torque the axle to frame pivot bolt and nut to specification.
20. Position the spindle to the axle and install the spindle pin, thrust bearing, and lock pin. Then, install the upper and lower spindle plugs.
21. Position the brake backing plate to the spindle and install the upper attaching bolts finger tight.
22. Position the spindle arm to the spindle and install the attaching bolts (except vehicles with integral spindle and spindle arm). Torque the upper and lower bolts to specification and install the cotter pins.
23. Adjust the brakes (Group 12) and install the wheel, hub, and drum on the spindle and adjust the wheel bearings.
24. Lower the truck and lubricate the steering linkage and spindle. Check toe-in and adjust as required.
25. Install the hub cap.

RADIUS ARM

Removal and Installation

1. Raise the front of the vehicle and place safety stands under the frame and a jack under the wheel or axle.
2. Disconnect the shock absorber from the radius arm bracket.
3. Remove two spring upper retainer attaching bolts from the top of the spring upper seat and remove the retainer (Fig. 7).
4. Remove the nut attaching the spring lower retainer to the lower seat and axle and remove the retainer.
5. Lower the axle and remove the spring.
6. Disconnect the steering rod from the spindle arm with Tool 3290-C.
7. Remove the spring lower seat and shim from the radius arm. Then, remove the bolt and nut attaching the radius arm to the axle.
8. Remove the cotter pin, nut and washer from the radius arm rear attachment.
9. Remove the bushing from the radius arm and remove the radius arm from vehicle.

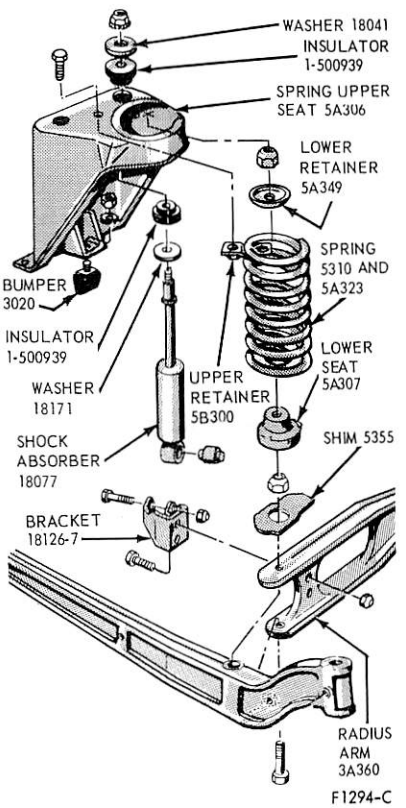

FIG. 7 Front Spring and Related Parts F-100,250 (Econoline and F-350 Similar)

10. Remove the inner bushing from the radius arm.
11. Position the radius arm to the axle and install the bolt and nut finger tight.
12. Install the inner bushing on the radius arm and position the arm to the frame bracket.
13. Install the bushing, washer, and attaching nut. Torque the nut to specification (Specifications appear at the end of the Part) and install the cotter pin.
14. Connect the steering rod to the spindle arm and install the attaching nut. Torque the nut to specification and install the cotter pin.
15. Torque the radius arm to axle attaching bolt and nut to specification.
16. Position the shim over the radius arm to axle attaching nut and install the spring lower seat (Fig. 7).
17. Place the spring in position and raise the front axle.
18. Position the spring lower retainer over the stud and lower seat, and install the attaching nut.
19. Position the upper retainer over the spring coil and against the spring upper seat, and install the 2 attaching bolts.
20. Torque the upper retainer attaching bolts and lower retainer attaching nut to specification.
21. Connect the shock absorber to the lower bracket.

Remove the jack and safety stands and lower the vehicle.

22. Check and adjust the toe if necessary.

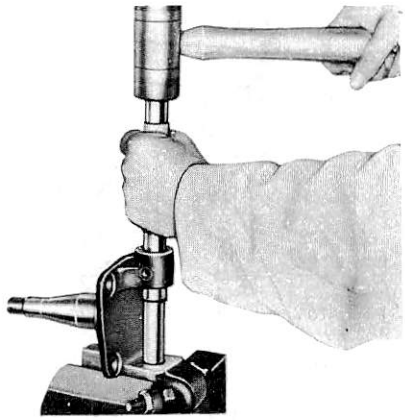

FIG. 8 Removing Bronze Bushing

SPINDLE BUSHING

Removal and Installation

1. On a spindle with bronze bushings, drive the bushing out of the spindle (Fig. 8) with a tool that is slightly smaller than the spindle bore. If a tool is not available, carefully drive a small center punch between the bushing and the spindle, at the split side of the bushing. Collapse the bushing, and remove it from the spindle bore.
2. Clean the spindle bores thoroughly, and make certain that the lubricating holes are not plugged.
3. Position a new bushing in the spindle bore with the lubricating hole in line with the lubricating fitting and the open end of the oil groove toward the axle. Drive a bronze bushing into the spindle (Fig. 9) with a driver that pilots in the bushing. It is not necessary to drive a Delrin bushing into place.
4. Install the remaining bushing in the same manner.
5. Bronze bushings should be reamed .001 to .003 inch larger than the diameter of a new spindle bolt (Fig. 10).**Do not ream Delrin bushings.**
6. Clean all the metal shavings from bronze bushings after *reaming, and* coat the bushing and pin with lubricant prior to assembly.

When a front or rear spring bushing is replaced on vehicles with steel backed bronze bushings, the split in the bushing must be installed directly opposite to the loaded side of the spring.

The bushing should be reamed .005 to .012 inch larger than the diameter of a new spring pin. After reaming, clean and coat the bushing and pin with C1AZ-19590-B lubricant prior to assembly

DESCRIPTION

FRONT SUSPENSION

F-100 4-WHEEL DRIVE—BRONCO

The front suspension consists of a driving axle which is attached to the truck frame with 2 coil springs, 2 radius arms, and a track bar (Figs. 1 and 3).

The radius arms clamp around the axle tube on each side and attach to frame brackets behind the front axle. A coil spring is attached to each radius arm directly above the axle and extends to the frame spring seat (Figs. 1 and 3). The shock absorbers are attached to the frame and to brackets on the radius arm.

The track bar is used to retain the front axle in position (side to side) with respect to the vehicle frame. It is attached to a bracket on the left frame side member and extends to the right side of the axle housing.

F-250 4-WHEEL DRIVE

The front suspension consists of a driving axle which is attached to the vehicle frame with 2 semi-elliptic leaf-type springs. Each spring is clamped to the axle with 2 U-bolts (Fig. 2). The front of the spring rests in a front shackle bracket. The rear of the spring is attached to a frame spring bracket.

The shock absorbers are the direct, double-acting type. They are attached to a frame bracket at the top and to an axle bracket at the lower end.

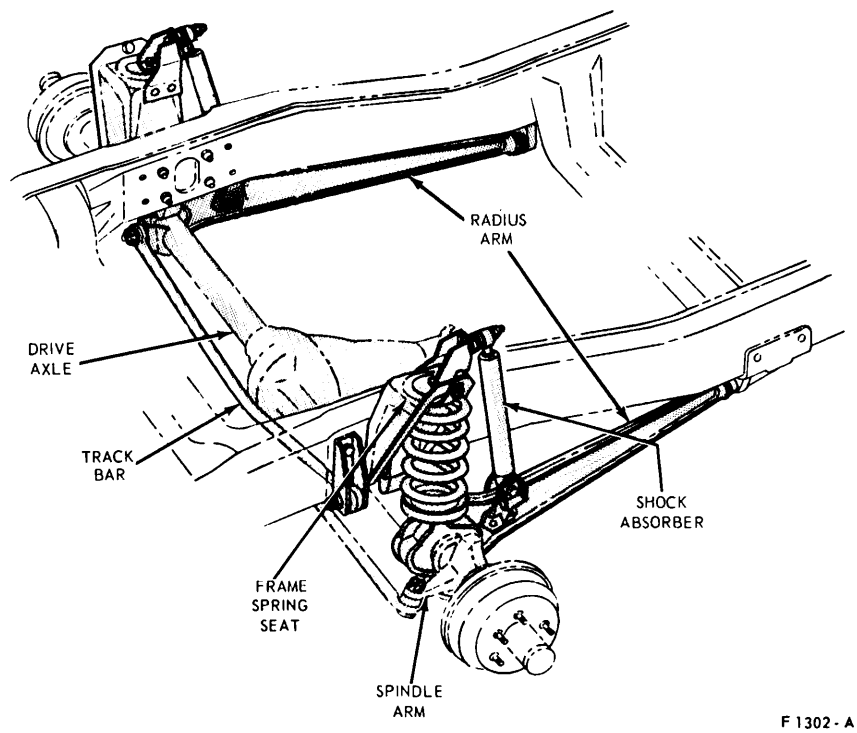

FIG. 1 Front Suspension—F-100 4-Wheel Drive

FRONT SHOCK ABSORBER

The hydraulic shock absorbers are of the direct, double-acting type. They provide a continuous damping effect both on compression and rebound. These shock absorbers are of telescopic design with rubber grommets at the mounting points for quiet operation. Since the shock absorbers are sealed, non-adjustable units, they must be replaced as complete assemblies.

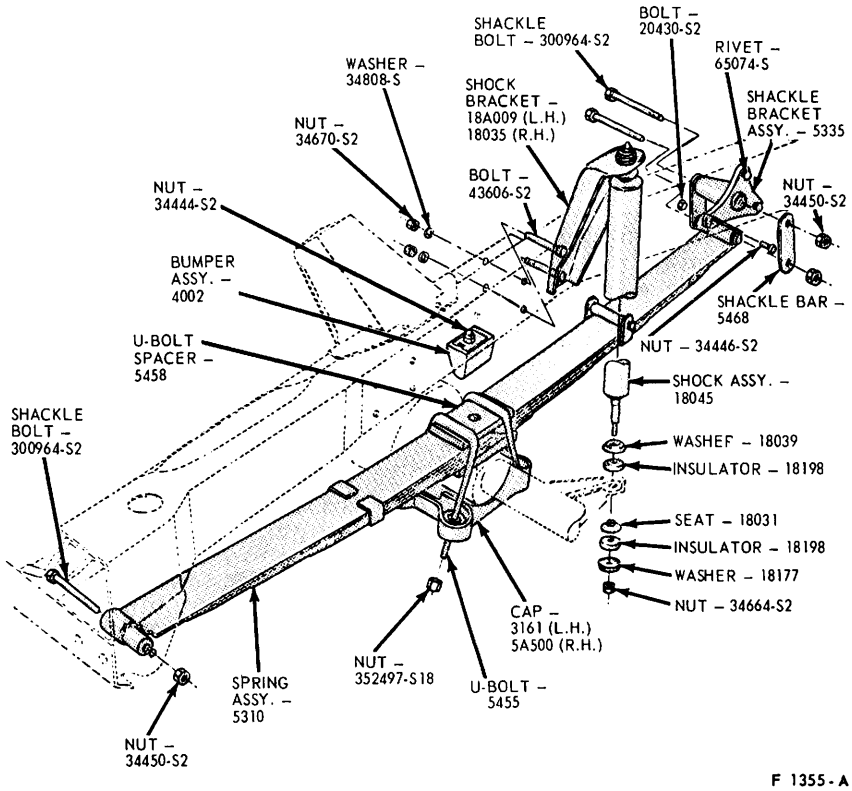

FIG. 2 Front Suspension—F-250 4-Wheel Drive

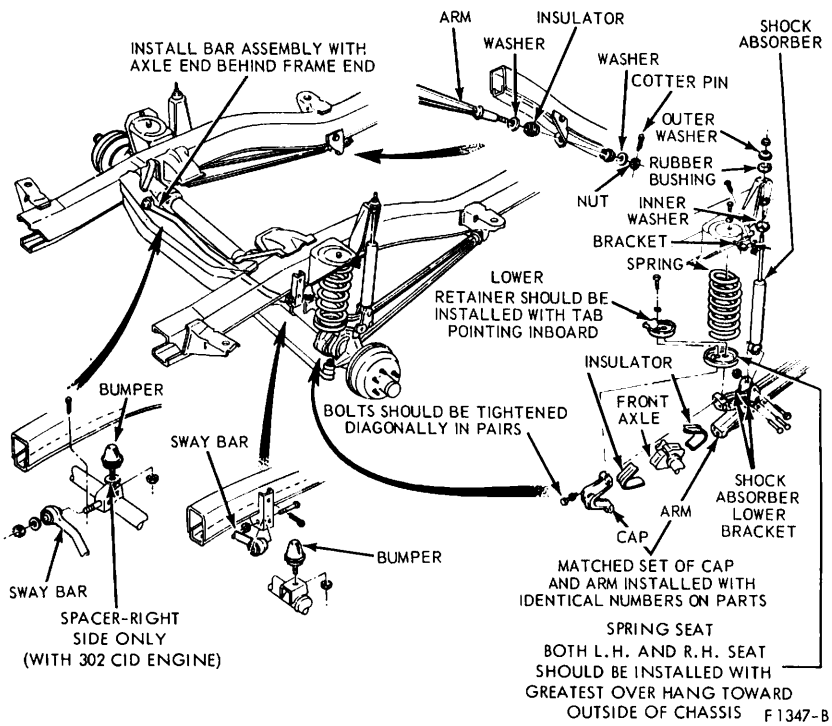

FIG. 3 Front Suspension—Bronco

REMOVAL AND INSTALLATION

FRONT SPRING

F-100 4-WHEEL DRIVE AND BRONCO

Removal and Installation

1. Raise the vehicle and remove the shock absorber-to-lower bracket attaching bolt and nut (Figs. 3 and 4). See Group 50 for Hoisting instructions.
2. Remove two spring lower retainer attaching bolts from inside of the spring coil.
3. Remove two spring upper retainer attaching bolts and nuts and remove the upper retainer.
4. Position safety stands under the frame side rails and lower the axle enough to relieve tension from the spring. Remove the spring, lower retainer and lower the spring from the vehicle.
5. Position the spring, spring lower seat, and the lower retainer to the frame spring pocket and the radius arm with the spring seat and the lower retainer positioned as shown in Figs. 3 and 4.
6. Position the upper retainer over the spring coil and loosely install the 2 attaching bolts and nuts.
7. Install the two lower retainer attaching bolts and torque to specification.
8. Tighten and torque the upper retainer attaching bolts to specification.
9. Position the shock absorber to the lower bracket and install the attaching bolt and nut. Torque the bolt and nut to specification and lower the vehicle.

F-250 4-WHEEL DRIVE

Removal and Installation

1. Raise the vehicle frame until the weight is off the front spring with the wheels still touching the floor.
2. Disconnect the lower end of the shock absorber from the axle. Remove the spring clips (U-bolts) and spring clip spacer (Fig. 2).
3. Remove the nut from the shackle bolt retaining the spring at the front. Drive out the shackle bolt.
4. Remove the nuts and shackle bar at the rear shackle bracket. Drive out the two shackle bolts and remove the spring.
5. Position the new spring on the spring seat cap and install the shackle bolts through the shackle bracket and spring.
6. Install the shackle bar and nuts on the shackle bolts. Tighten to specification (90-130 ft-lbs).
7. Position the front of the spring to allow the front shackle bolt to be installed. Install the bolt nut and tighten to specifications (90-130 ft-lb).
8. Position the spring clip spacer and place the spring clips (U-bolts) in position through the holes in the spring seat cap. Install but do not tighten the U-bolt nuts.
9. Connect the lower end of the shock absorber to the axle.
10. Lower the vehicle and torque the U-bolt nuts to specification (100-135 ft-lb).

FRONT WHEEL SPINDLE

Removal and Installation

Refer to Group 15 for spindle replacement on 4-wheel drive front axles.

FRONT SHOCK ABSORBER

F-100-250 4-WHEEL DRIVE

Removal and Installation

To replace the front shock absorber, remove the self-locking nut, steel

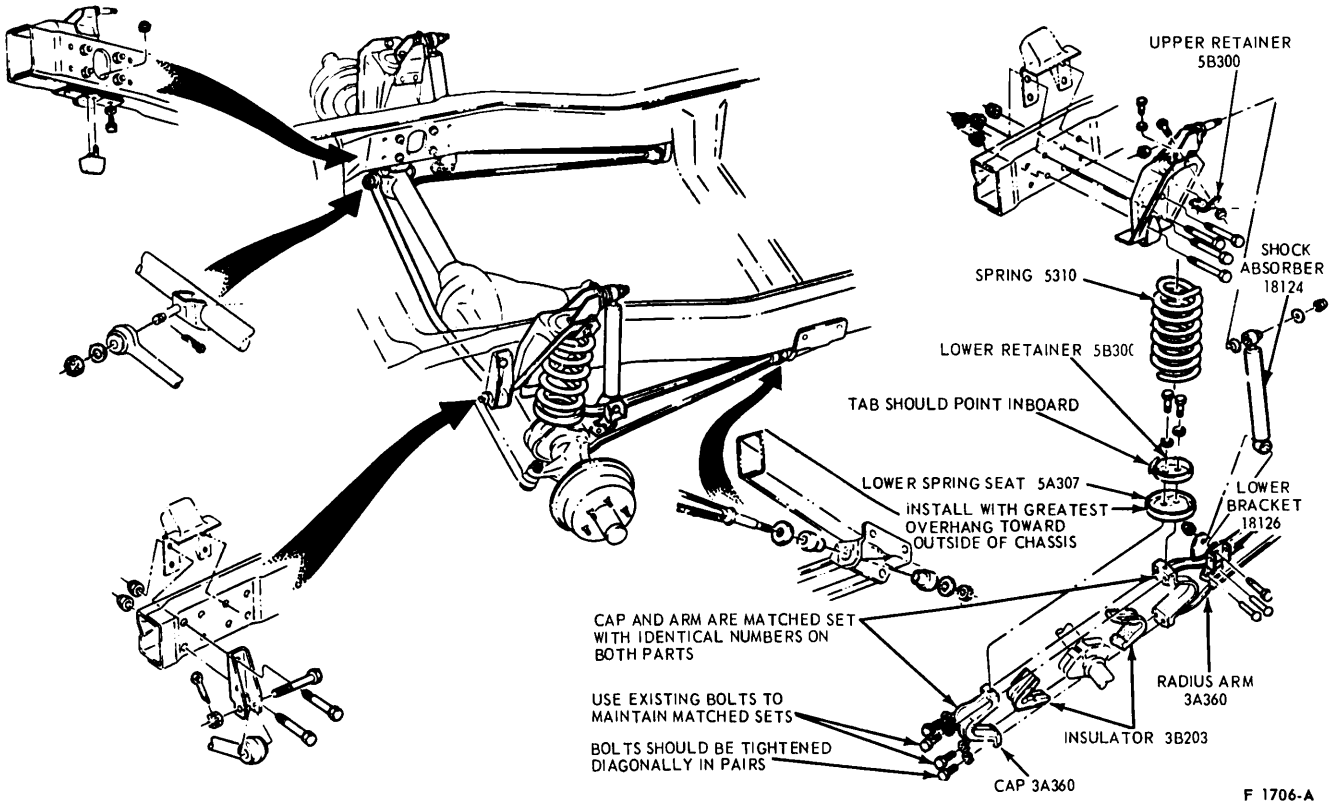

FIG. 4 Front Suspension Disassembled—F-100 4-Wheel Drive

washer, and rubber bushings at the upper and lower ends of the shock absorber except F-100-350 models. On F-100-350 models, the lower end of the shock absorber is attached to a bracket (mounted on the radius arm) by a bolt and nut. Remove the shock absorber.

When installing a new shock absorber, use new rubber bushings. Position the shock absorber on the mounting brackets with the large diameter at the top.

Install the rubber bushing, steel washer, and self-locking nut. Torque to specification.

BRONCO

Removal and Installation

1. Remove the bolt and nut attaching the shock absorber to the lower bracket on the radius arm (Fig. 3).
2. Remove the nut, washer, and insulator from the shock absorber at the frame bracket and remove the shock absorber.
3. Position the washer and insulator on the shock absorber rod and position the shock absorber to the frame bracket.
4. Position the insulator and washer on the shock absorber rod and install the attaching nut loosely.
5. Position the shock absorber to the lower bracket and install the attaching bolt and nut loosely.
6. Torque the attaching bolts and nuts to specification.

FRONT AXLE

Removal and Installation

Refer to Group 15 for front axle removal and installation procedures on 4-wheel drive vehicles.

RADIUS ARM

F-100 4-WHEEL DRIVE, BRONCO

Removal and Installation

1. Raise the vehicle and position safety stands under the frame side rails.
2. Remove the shock absorber-to-lower-bracket attaching bolt and nut (Figs. 3 and 4), and pull the shock absorber free of the radius arm.
3. Remove two spring lower retainer attaching bolts from inside of the spring coil.
4. Remove the cotter pin and nut attaching the radius arm to the frame bracket and remove the radius arm rear insulator.
5. Remove four bolts attaching the radius arm cap to the radius arm and remove the cap and insulator. **The cap and radius arm are a matched set with identical numbers (Figs. 3 and 4) on each part and should not be mixed.**
6. Move the axle forward and remove the radius arm and insulator from the axle. Then, pull the radius arm from the frame bracket.

The radius arm and cap must be identified by a T on each piece in addition to a number (1 through 100). If no T identification is found on an arm and cap, it must not be used on F-100 4-wheel drive vehicles.

7. Position the washer and insulator on the rear of the radius arm and insert the radius arm and insulator into the frame bracket.
8. Position the rear insulator and washer on the radius arm and loosely install the attaching nut.
9. Position the insulator on the axle and position the radius arm to the insulator and axle.
10. Position the front insulator to the axle and install the radius arm cap with the numbers on the radius arm and cap together. Torque the attaching bolts diagonally in pairs to specification.
11. Position the spring lower seat and retainer to the spring and axle (Figs. 3 and 4) and install the two attaching bolts. Torque the bolts to specification.
12. Torque the radius rod rear attaching nut to specification and install the cotter pin.
13. Position the shock absorber to the lower bracket and install the attaching bolt and nut. Torque the nut to specification and lower the vehicle.

DESCRIPTION

REAR SUSPENSION

F-100, 250, 350 (4 X 2) AND ECONOLINE

Semi-elliptic, leaf-type springs are used for the rear axle suspension. The forward end of each spring is attached to a bracket on the frame side member. The rear end of each spring is shackled to a bracket on the frame side member. (Figs. 1, 2, 3 and 4).

Optional auxiliary rear springs are mounted on top of the main spring with free ends. These provide increased load carrying capacity and stability (Fig. 4).

ALL VEHICLES EXCEPT F-100, 250, 350, BRONCO AND ECONOLINE

Semi-elliptic, leaf-type rear springs are used on all vehicles except tandem models (Figs. 5, 6, 7 and 8). The springs are mounted to the frame side members, and are held in place on the axles by spring clips (U-bolts).

The front and rear ends of the springs are mounted on the frame side rails by either a locking bracket, a slipper type pad, a shackle, or a supporting bracket and rebound pin.

F-100 4-WHEEL DRIVE, BRONCO

Semi-elliptic, leaf-type springs are used for the rear axle suspension (Fig. 9). The front end of each spring is attached to a bracket on the frame side member. The rear end of each spring is attached to a bracket on the frame side member with a shackle. Each spring is attached to the axle with two U-bolts. A spacer is located between the spring and the axle to obtain a level ride position.

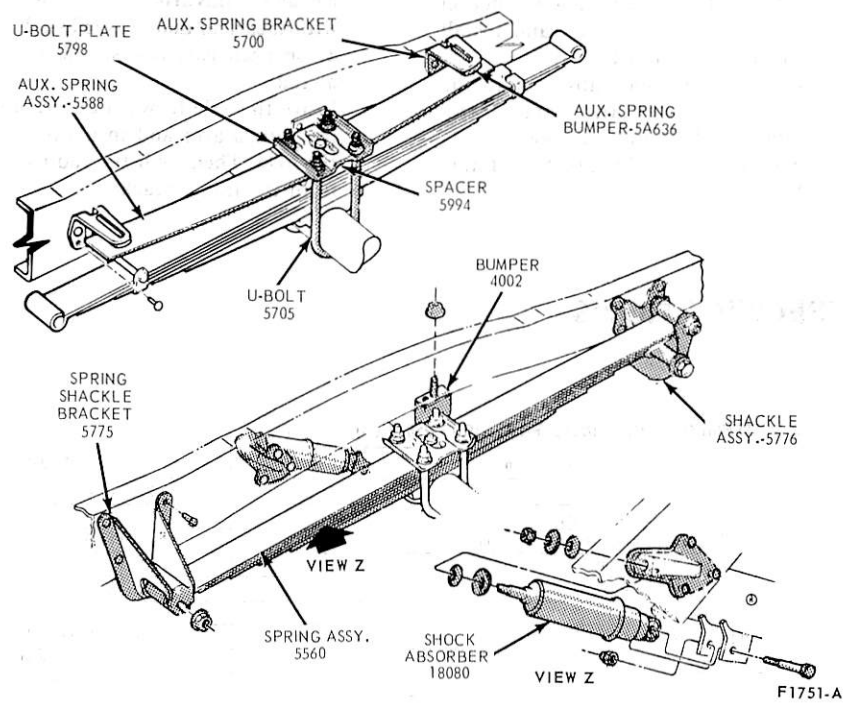

FIG. 1 Rear Spring Installation—F-100-250

F-250 4-WHEEL DRIVE, P-SERIES

Semi-elliptic, leaf-type springs are used for the rear axle suspension (Fig. 10). The front end of each spring is attached to a spring bracket on the frame side member. The rear end of each spring is attached to a bracket on the frame side member with a shackle. Each spring is attached to the axle with two U-bolts. A spacer is located between the spring and the axle to obtain a level ride position.

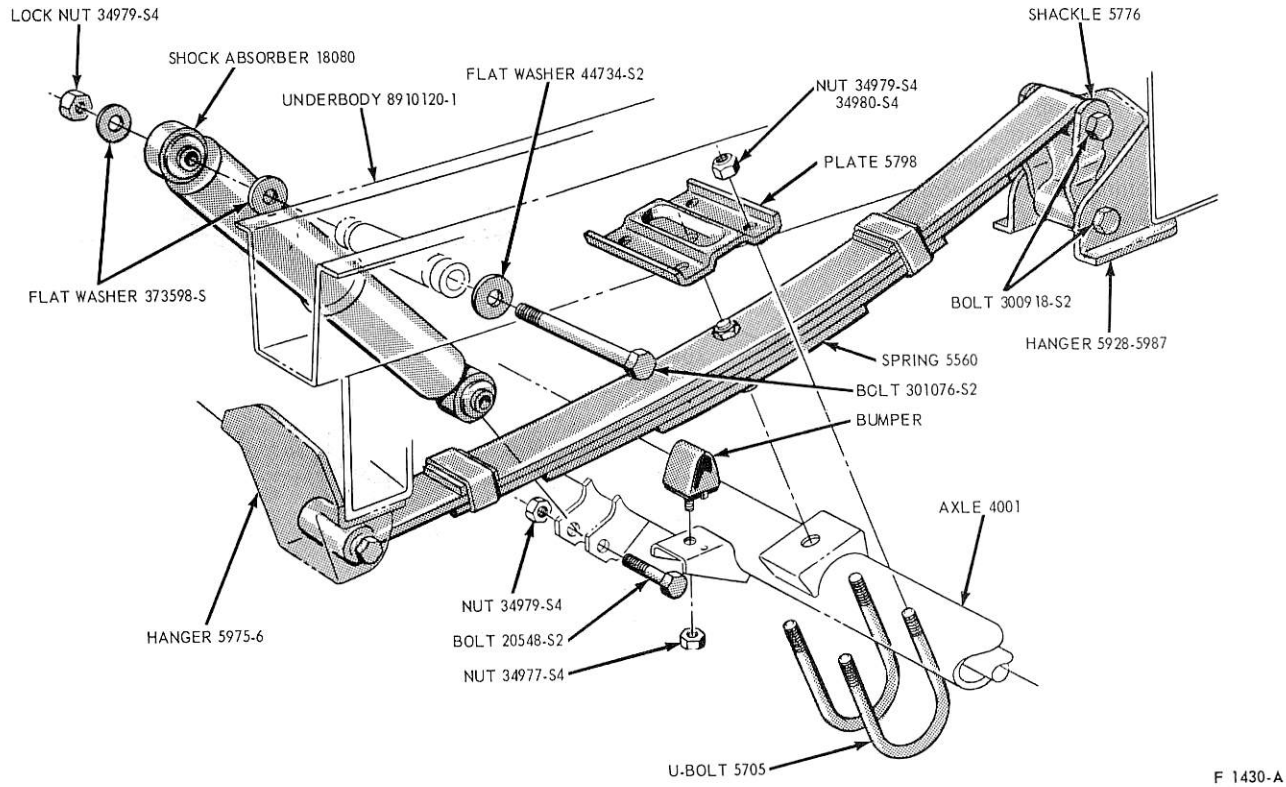

FIG. 2 Rear Spring Installation—E-100-200

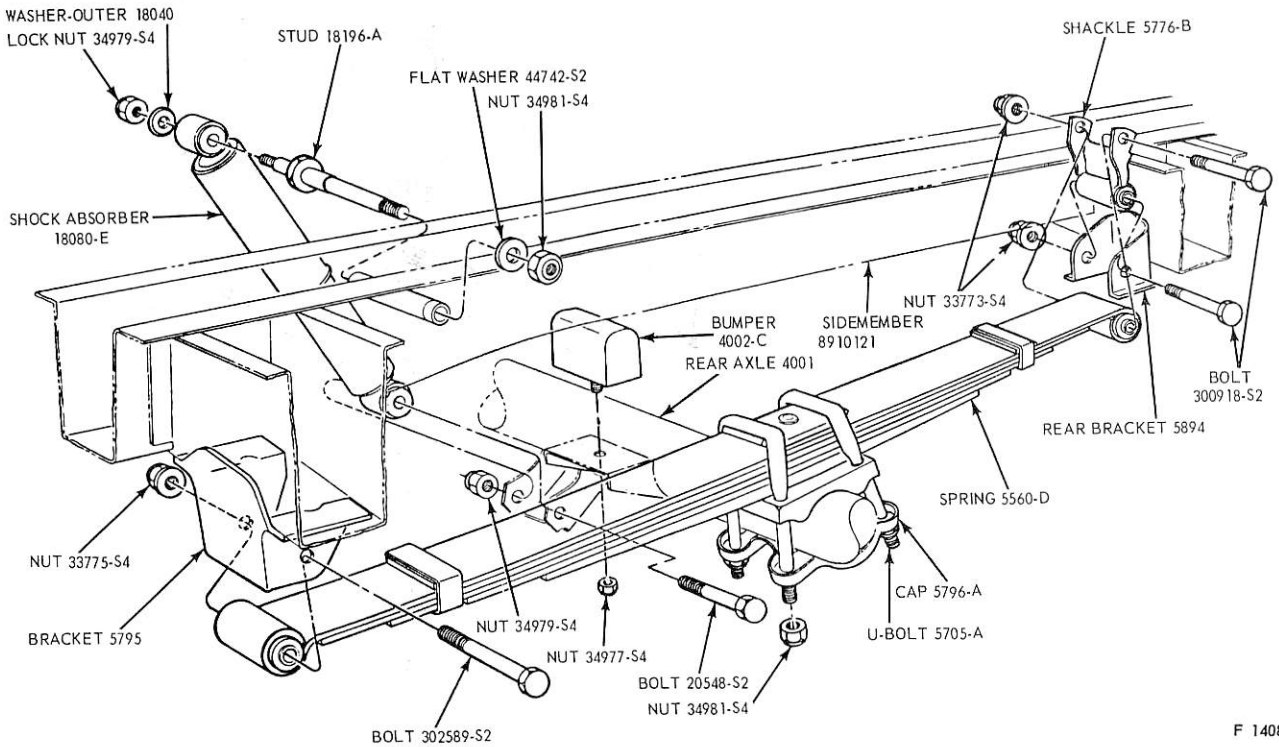

FIG. 3 Rear Spring Installation—E-300

REAR SHOCK ABSORBER

The hydraulic shock absorbers are of the direct, double-acting type. They provide a continuous damping effect both on compression and rebound. These shock absorbers are of telescopic design with rubber grommets at the mounting points for quiet operation. Since the shock absorbers are sealed, non-adjustable units, they must be replaced as complete assemblies.

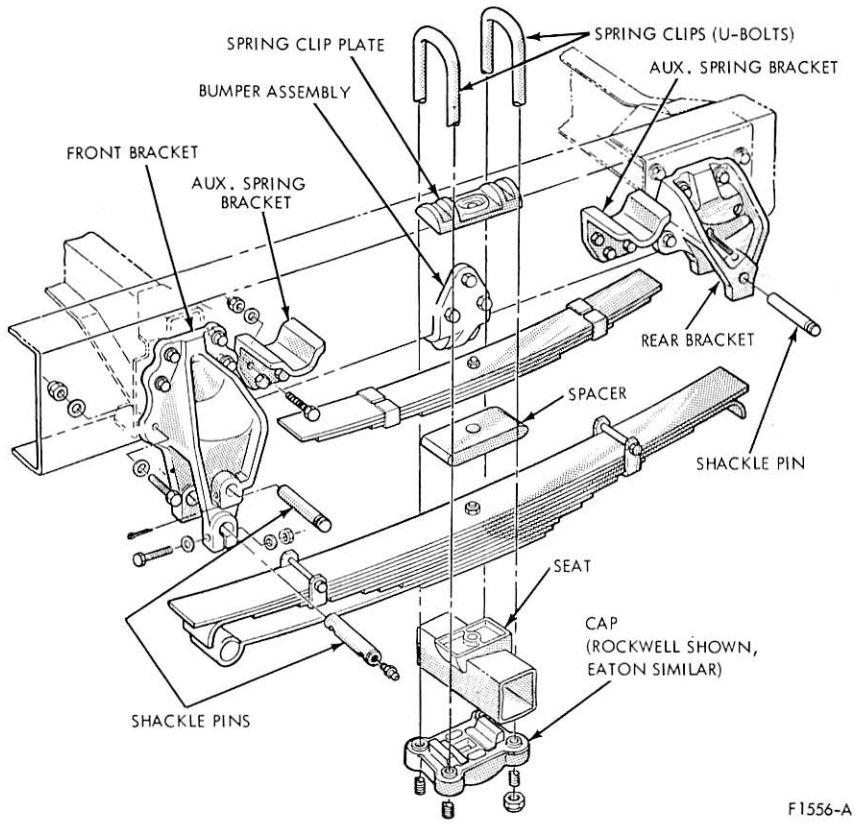

FIG. 8 Rear Spring Installation—W-900

REMOVAL AND INSTALLATION

REAR SHOCK ABSORBER

ECONOLINE, BRONCO

Removal and Installation

1. Raise the vehicle on a hoist.
2. Remove the shock absorber lower attaching nut and bolt, and swing the lower end free of the mounting bracket on the axle housing (Fig. 11).
3. Remove the attaching nut from the upper mounting stud, and remove the shock absorber.
4. Transfer the sleeves from the upper and lower bushings to the replacement shock absorbers. If worn or damaged, use new sleeves.
5. Position the replacement shock absorber with rubber bushings and steel washers to the upper mounting bolt.
6. Swing the lower end of the shock absorber into the mounting bracket on the axle housing and install the washers, mounting bolt, and self-locking nut. Torque the nut to specification.
7. Install the self-locking nut on the upper mounting bolt. Torque the nut to specification.

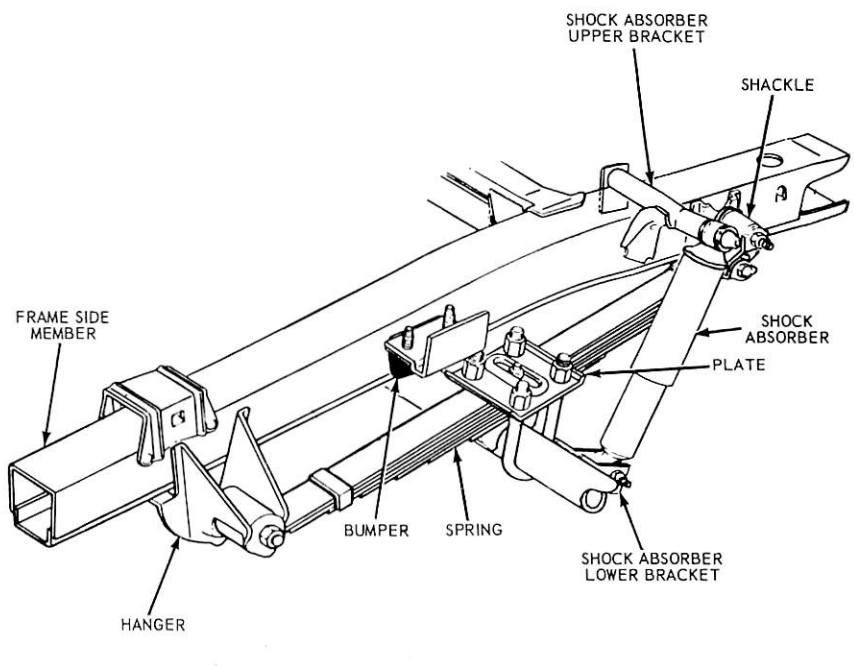

FIG. 9 Rear Suspension—Bronco

ALL VEHICLES EXCEPT ECONOLINE AND BRONCO

Removal and Installation

To replace the rear shock absorber, remove the self-locking nut, steel washer, and rubber bushings at the upper and lower ends of the shock absorber. Remove the shock absorber.

When installing a new shock absorber, use new rubber bushings. Position the shock absorber on the mounting brackets with the large diameter at the top.

Install the rubber bushing, steel washer, and self-locking nut. Tighten the nut until it rests against the shoulder of the stud.

REAR SPRING

F-100, 250

Removal and Installation

1. Raise the vehicle frame until the weight is off the rear spring, with the wheels still touching the floor.
2. Remove the nuts from the spring clips (U-Bolts) and drive the clips out of the spring clip plate. If so equipped, remove the auxiliary spring and spacer.
3. Remove the spring to bracket nut and bolt at the front of the spring.
4. Remove the shackle upper and lower nuts and bolts at the rear of the spring. Remove the spring and shackle assembly from the rear shackle bracket.
5. If the bushing in the spring or shackle are worn or damaged, remove them.
6. If required, install new bushings in the spring and the shackle.
7. Position the spring in the shackle, and install the upper shackle to spring bolt and nut with the bolt head facing outboard.
8. Position the front end of the spring in the bracket and install the bolt and nut.
9. Position the shackle in the rear bracket and install the bolt and nut.
10. Position the spring on top of the axle with the spring tie bolt centered in the hole provided in the seat. If so equipped, install the auxiliary spring and spacer.
11. Install the spring clips, spring clip plate, and nuts.
12. Lower the vehicle to the floor and torque the spring bolt nuts and spring clip nuts (U-bolts) to specifications. Torque the front spring bolt and nut and the rear shackle bolts and nuts.

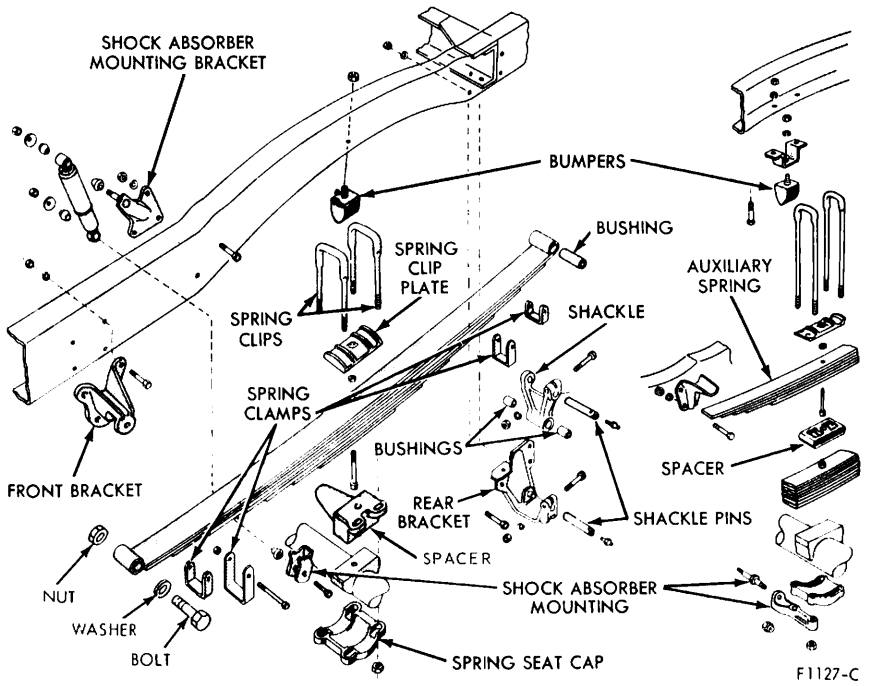

FIG. 10 Rear Suspension—F-250 4 Wheel Drive (P-Series similar)

E-100, 200

Removal and Installation

1. Raise the rear end of the vehicle and support the chassis with safety stands. Support the rear axle with a floor jack or hoist.
2. Disconnect the lower end of the shock absorber from the bracket on the axle housing (Fig. 2).
3. Remove the two U-bolts and plate.
4. Lower the axle and remove the upper and lower rear shackle bolts.
5. Pull the rear shackle assembly and rubber bushings from the bracket and spring.
6. Remove the nut and mounting bolt that secures the front end of the spring. Remove the spring assembly from the front shackle bracket.
7. Install new rubber bushings in the rear shackle bracket and in the rear eye of the replacement spring.
8. Position the spring assembly and connect the front eye of the spring to the front shackle bracket by installing the front mounting bolt and nut. Do not tighten the nut.
9. Mount the rear end of the spring by inserting the upper bolt of the rear shackle assembly through the eye of the spring and the lower bolt through the rear spring hanger.
10. Position the spring center bolt to the pilot hole in the axle and install the plate. Install the U-bolts through the plate. Do not tighten the attaching nuts at this time.
11. Raise the axle with a floor jack or hoist until the vehicle is free of the stands and connect the lower end of the shock absorber to the bracket on the axle housing (Fig. 2).
12. Torque the spring front mounting bolt and nut, the rear shackle nuts and the U-bolt nuts to specifications.
13. Remove the safety stands and lower the vehicle.

E-300

Removal and Installation

1. Raise the rear end of the vehicle and support the chassis with safety stands. Support the rear axle with a floor jack or hoist.
2. Disconnect the lower end of the shock absorber from the bracket on the axle housing (Fig. 3).
3. Remove the two spring clips (U-bolts) and the spring clip cap.
4. Lower the axle and remove the spring front bolt from the hanger.
5. Remove the two attaching bolts from the rear of the spring. Remove the spring and the shackle.
6. Assemble the upper end of the shackle to the spring with the attaching bolt as shown in Fig. 3.
7. Connect the front of the spring to the front bracket with the attaching bolt.

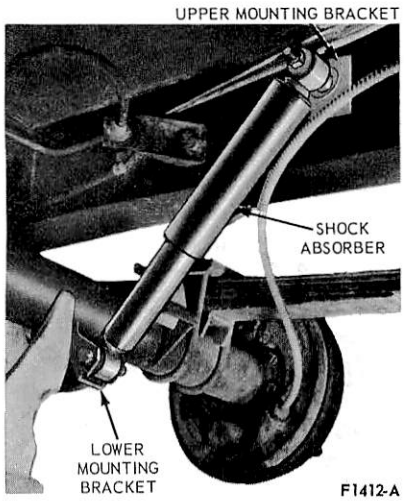

FIG. 11 Rear Shock Absorber Installed

8. Assemble the spring and shackle to the rear bracket with the attaching bolt.
9. Place the spring clip plate over the head of the center bolt.
10. Raise the axle with a jack and guiding it so that the center bolt enters the pilot hole in the pad on the axle housing.
11. Install the spring clips, cap and attaching nuts. Tighten the nuts snugly.
12. Connect the lower end of the shock absorber to the lower bracket.
13. Torque the spring front mounting bolt and nut, the rear shackle nuts and spring clip nuts to specifications.
14. Remove the safety stands and lower the vehicle.

F-100, F-250 4-WHEEL DRIVE AND P-SERIES

Removal and Installation

1. Raise the vehicle frame until the weight is off the rear springs with the wheels still touching the floor.
2. Remove the nuts from the spring clips (U-bolts) and drive the clips out of the spring seat cap and remove the spring clip plate (Figs. 1 and 10). If the truck is so equipped, remove the auxiliary spring and spacer.
3. Remove the shackle pin locking bolts from each end of the spring (bolt and nut on F-250 4 x 4 front eye).
4. Working from the inner side of the frame, insert a drift in the hole provided in the frame for removing the shackle pin. Drive the shackle pin out of each spring bracket (bolt on F-250 4 x 4 front eye).
5. Remove the spring and shackle from the vehicle. On F-100-250 4 x 4 models, remove the spring to axle spacer.
6. Drive out the remaining shackle pin from the rear spring eye and remove the shackle from the spring.
7. Position the shackle to the rear spring eye.
8. Install the shackle pin through the shackle and spring eye with the lubricator fitting on the shackle pin facing outward.
9. Line up the shackle pin lock bolt groove with the lock bolt hole in the shackle. Install the lock bolt, lock washer, and nut.
10. Position the spring on the axle, making sure that the spring tie bolt is in the hole provided in the axle spring seat or spacer. On F-100-250 4 x 4 models, first install the spacer between the spring seat and the spring, making sure the spacer dowel is positioned in the pilot hole of the axle spring seat.
11. Install a shackle pin through the shackle and rear bracket, with the lubricator fitting on the shackle pin facing outward. Line up the pin groove with the lock bolt hole in the bracket, and install the lock bolt, lock washer, and nut as before.
12. Repeat this operation to install a shackle pin at the front bracket and spring eye (bolt on F-250 4 x 4).
13. If so equipped, install the auxiliary spring and spacer. Place the spring clip plate on top of the spring at the tie bolt, and put the spring clips over the spring assembly and axle.
14. Position the spring seat cap, and install the nuts on the spring clips.
15. Lower the vehicle to the floor and torque the spring clip nuts to specifications. Lubricate the fittings on the shackle pins.

BRONCO

Removal and Installation

1. Raise the vehicle by the axles and install safety stands under the frame.
2. Disconnect the shock absorber from the axle.
3. Remove the U-bolt attaching nuts and remove the 2 U-bolts and the spring clip plate (Fig. 9).
4. Lower the axle to relieve spring tension and remove the nut from the spring front attaching bolt.
5. Remove the spring front attaching bolt from the spring and hanger with a drift.
6. Remove the nut from the shackle to hanger attaching bolt and drive the bolt from the shackle and hanger with a drift and remove the spring from the vehicle.
7. Remove the nut from the spring rear attaching bolt (Fig. 9). Drive the bolt out of the spring and shackle with a drift.
8. Position the shackle (closed section facing toward front of vehicle) to the spring rear eye and install the bolt and nut.
9. Position the spring front eye and bushing to the spring front hanger, and install the attaching bolt and nut.
10. Position the spring rear eye and bushing to the shackle, and install the attaching bolt and nut.
11. Raise the axle to the spring and install the U-bolts (when an axle cap is not used, the U-bolt shank should contact the leaf edges) and spring clip plate. Align the spring leaves.
12. Torque the U-bolt nuts and the spring front and rear attaching bolt nuts to specification. The U-bolts should contact the spring assembly edges or axle seat.
13. Connect the shock absorber to the axle and torque the nut to specification.
14. Remove the safety stands and lower the vehicle.

F-350

Removal and Installation

1. Raise the vehicle frame until the weight is off the rear springs with the wheels still touching the floor.
2. Remove the nuts from the spring U-bolts.
3. Drive the U-bolts out of the shock absorber lower bracket and the spring cap and remove the U-bolts (Fig. 4).
4. Remove the spacer from the top of the spring.
5. If equipped with auxiliary springs, remove the auxiliary spring and spacer (Fig. 4).
6. Remove the shackle to bracket bolt and nut from the rear of the spring.
7. Remove the spring to hanger bolt and nut from the front of the spring and remove the spring.
8. Remove the shackle to spring bolt and nut and remove the shackle from the spring.
9. Position the shackle to the spring and install the attaching bolt and nut. The bolt must be installed so the nut is away from the frame (Fig. 4).
10. Position the spring to the spring front hanger and install the attaching bolt and nut (Fig. 4).
11. Position the shackle to the bracket and install the attaching bolt and nut.

12. Align the spring toe bolt with the pilot hole in the axle spring seat and, if so equipped, install the auxiliary spring and spacer (Fig. 4).
13. Position the spacer on top of the spring and install the U-bolts over the spacer, spring and axle.
14. Position the spring cap and shock lower bracket to the axle and U-bolts. Install the U-bolt attaching nuts.
15. Lower the vehicle and torque the front spring bracket bolt and nut and the rear shackle bolts and nuts to specification.

C-SERIES

Removal and Installation

1. Raise the vehicle frame until the weight is off the rear springs with the wheels still touching the floor.
2. Remove the nuts from the spring clips (U-bolts) and drive the clips out of the spring seat cap (Fig. 5). If so equipped, remove the auxiliary spring and spacer.
3. Remove the shackle pin locking bolts from each spring bracket.
4. A hole is provided in the frame opposite each spring bracket for removing the shackle pin. Insert a drift from the inside of the frame through these holes and drive the shackle pin out of each bracket.
5. Remove the spring and shackle assembly from the truck. Separate the spring from the shackle by removing the locking bolt and driving out the shackle lower pin from the shackle and spring eye.
6. Remove the lubrication fittings from the shackle pins.
7. Align the upper bore of the shackle with the holes in the rear bracket. Drive the shackle upper pin through the shackle and bracket with the pin lubricator hole facing outward.
8. Line up the shackle pin groove with the locking bolt hole in the bracket and install the locking bolt, washer and nut.
9. Install the spring seat and the wedge (if so equipped) between the axle and the spring (Fig. 8). Position the spring on the axle, being sure that the spring tie bolt is in the hole provided in the axle or spring seats. **If so equipped, install the auxiliary spring and spacer.**
10. Drive the shackle lower pin through the shackle and spring rear eye. Install the locking bolt, washer and nut as before. Repeat the operation to install the shackle pin through the spring front bracket and eye.
11. Place the spring clip plate on top of the spring at the tie bolt, and put the spring clips over the spring assembly and the axle.
12. Install the spring seat cap on the spring clips and install the spring clip nuts on the clips.
13. Lower the vehicle to the floor and tighten the spring clip nuts to specified torque.

L-LN-B-W-SERIES

Removal and Installation

1. Raise the vehicle frame until the weight is off the rear springs with the wheel still touching the floor.
2. Remove the nuts from the spring clips (U-bolts) and drive the clips out of the spring seat cap (Figs. 6, 7 and 8). Remove the auxiliary spring and spacer.
3. Support the spring, and remove the front shackle pins. The upper pin is held in place by a cotter pin, and the lower pin by lock bolts (Figs. 6, 7 and 8).
4. Remove the rear shackle pin, which is held in place by a cotter pin, and remove the spring.
5. Position the spring in the rear bracket and install the shackle pin and cotter pin.
6. Position the spring in the front bracket. Install the upper shackle pin, and secure with a cotter pin.
7. Using a C-clamp or jack, force the front eye of the spring up into the bracket so that the eye is aligned with the holes in the bracket. Install the lower shackle pin through the front bracket and spring eye. Align the pin groove with locking bolt hole in the bracket, install the locking bolt and nut, and tighten to specifications.
8. Position the spring seat and wedge (if so equipped) between the axle and spring (Figs. 6, 7 and 8). If so equipped, install the auxiliary clip plate on top of the spring at the tie bolt, and put the spring clips over the spring assembly and axle.
9. Install the spring seat cap on the spring clips and install the spring clip nuts on the clips.
10. Lower the vehicle to the floor and tighten the spring clip nuts to specified torque.

DESCRIPTION

REAR SUSPENSION—TANDEM

The RUE extended leaf suspension consists of conventional stacked leaf springs with the top two leaves extended to the rear (Fig. 1). A two-stage spring action on the tandem suspension is created when the top two spring leaves come into contact with a second, inner hanger. When the vehicle is empty, the sprung weight is carried by the rearmost hanger and most of the spring deflection is through the top two leaves. As the load increases, the inner hanger comes in contact with the spring. At contact the effective spring length is reduced, increasing the spring rate.

The SR shear-ride suspension consists of four two-stage rubber shear springs which carry and cushion the load (Fig. 2). When the vehicle is lightly loaded, the first stage provides a soft deflection rate conducive to good riding. As the load is increased, a flange on the vertical drive pin cushions out the first stage. In this manner spring deflection rate is increased.

The RS rubber load cushion suspension system utilizes four cored rubber cushions which replace the steel leaf springs of the conventional suspension and is particularly effective with varying loads (Fig. 3). Aluminum saddles, walking beams and rubber cushions offer a weight advantage over spring suspensions. Equalizing beam design distributes the load equally between the axles.

The RT and RU steel leaf suspensions have conventional stacked leaf springs (Fig. 4). Equalizing beams and the below-axle load design absorbs strain, twist and road shock. Some models have 10 leaf springs, others 12 leaves.

REMOVAL AND INSTALLATION

REAR SPRING

RU, RUE, AND RT SUSPENSIONS

Removal and Installation

1. Raise the rear of the vehicle and position the blocks under the frame behind the rear axle.
2. Remove the wheels and the hub and drum from the forward rear axle.
3. Remove the support beam bar saddle caps from the lower side of the support beam.
4. Position a jack under the front end of the support beam.
5. Remove the shackle pin lock pin from the spring front bracket and remove the shackle pin (Figs. 1 and 4).
6. Lower the support beam and spring and remove the spring from the support beam.
7. RU and RUE Suspension Only—Remove the U-bolt nuts and remove the saddle and U-bolts from the spring.
8. RT Suspension Only—Remove the spring plate to support beam saddle attaching bolts and nuts. Remove the saddle and spring plate from the spring.
9. RU and RUE Suspension Only—Position and saddle to the

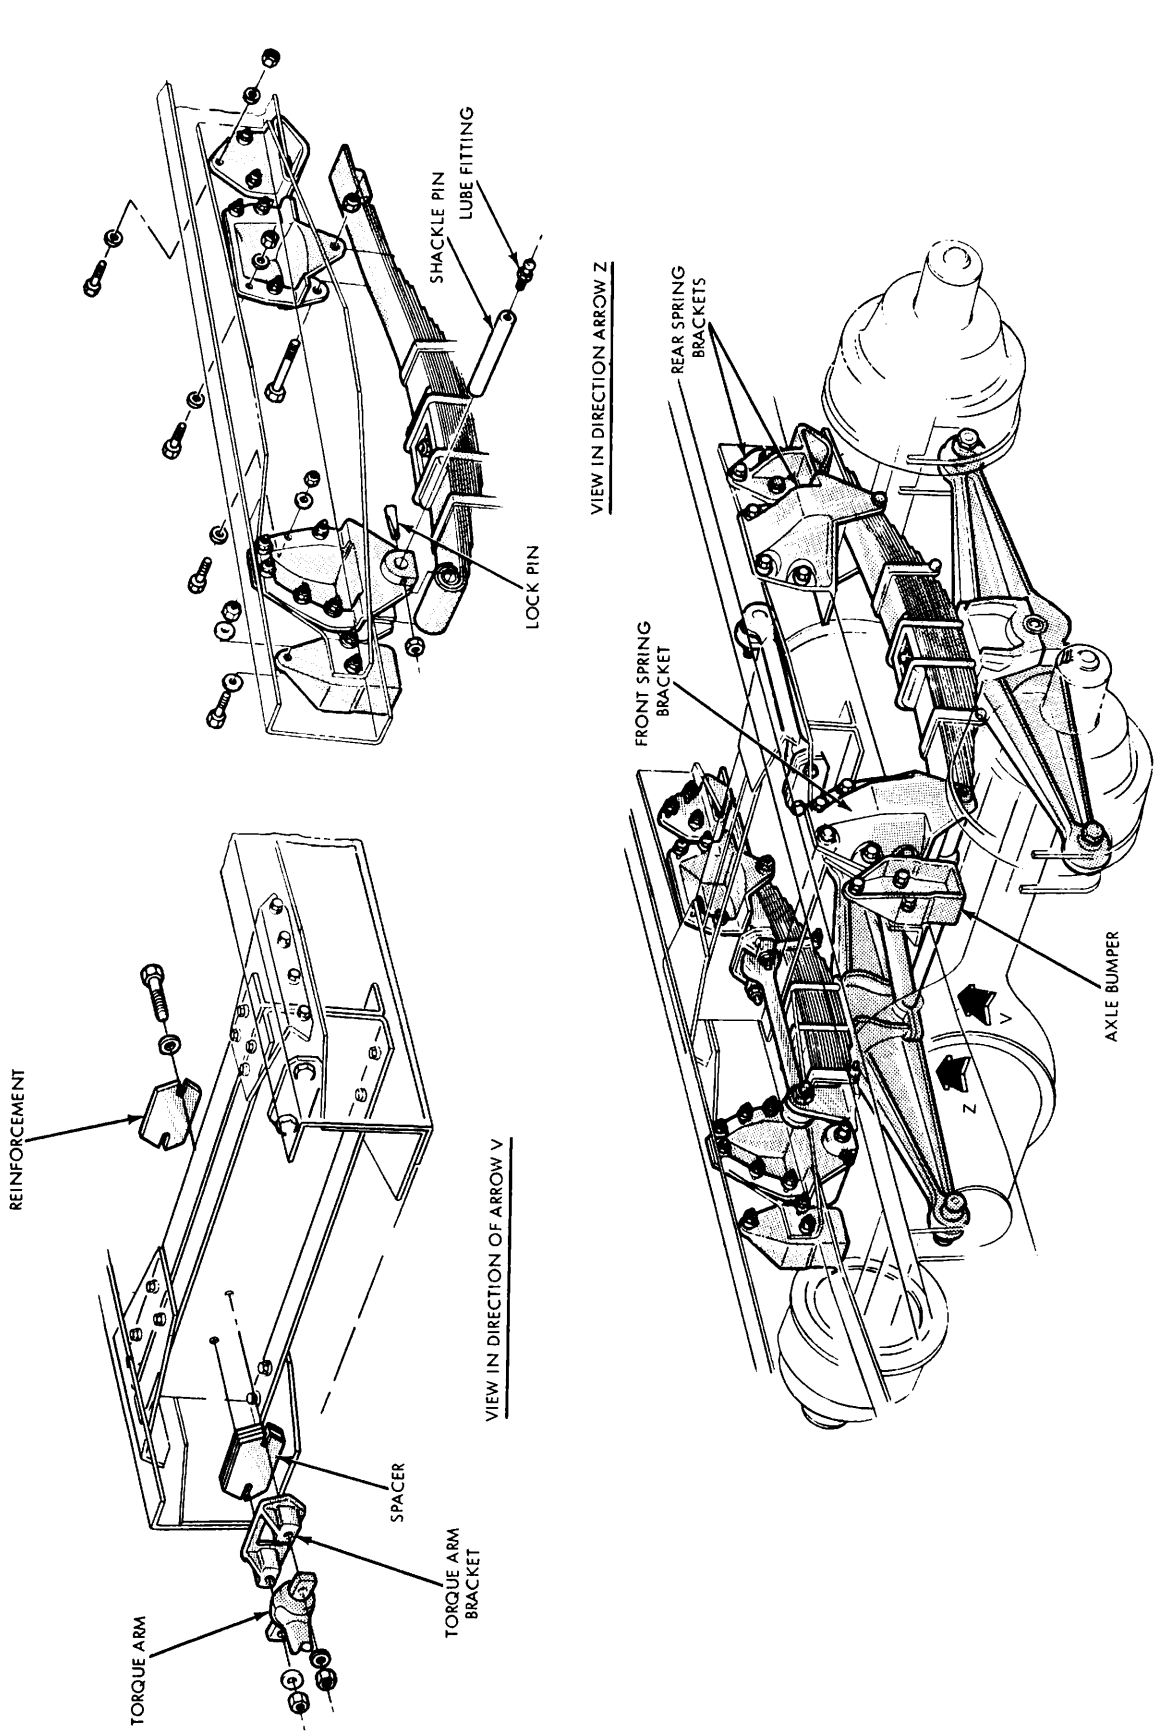

FIG. 1 RUE Tandem Suspension

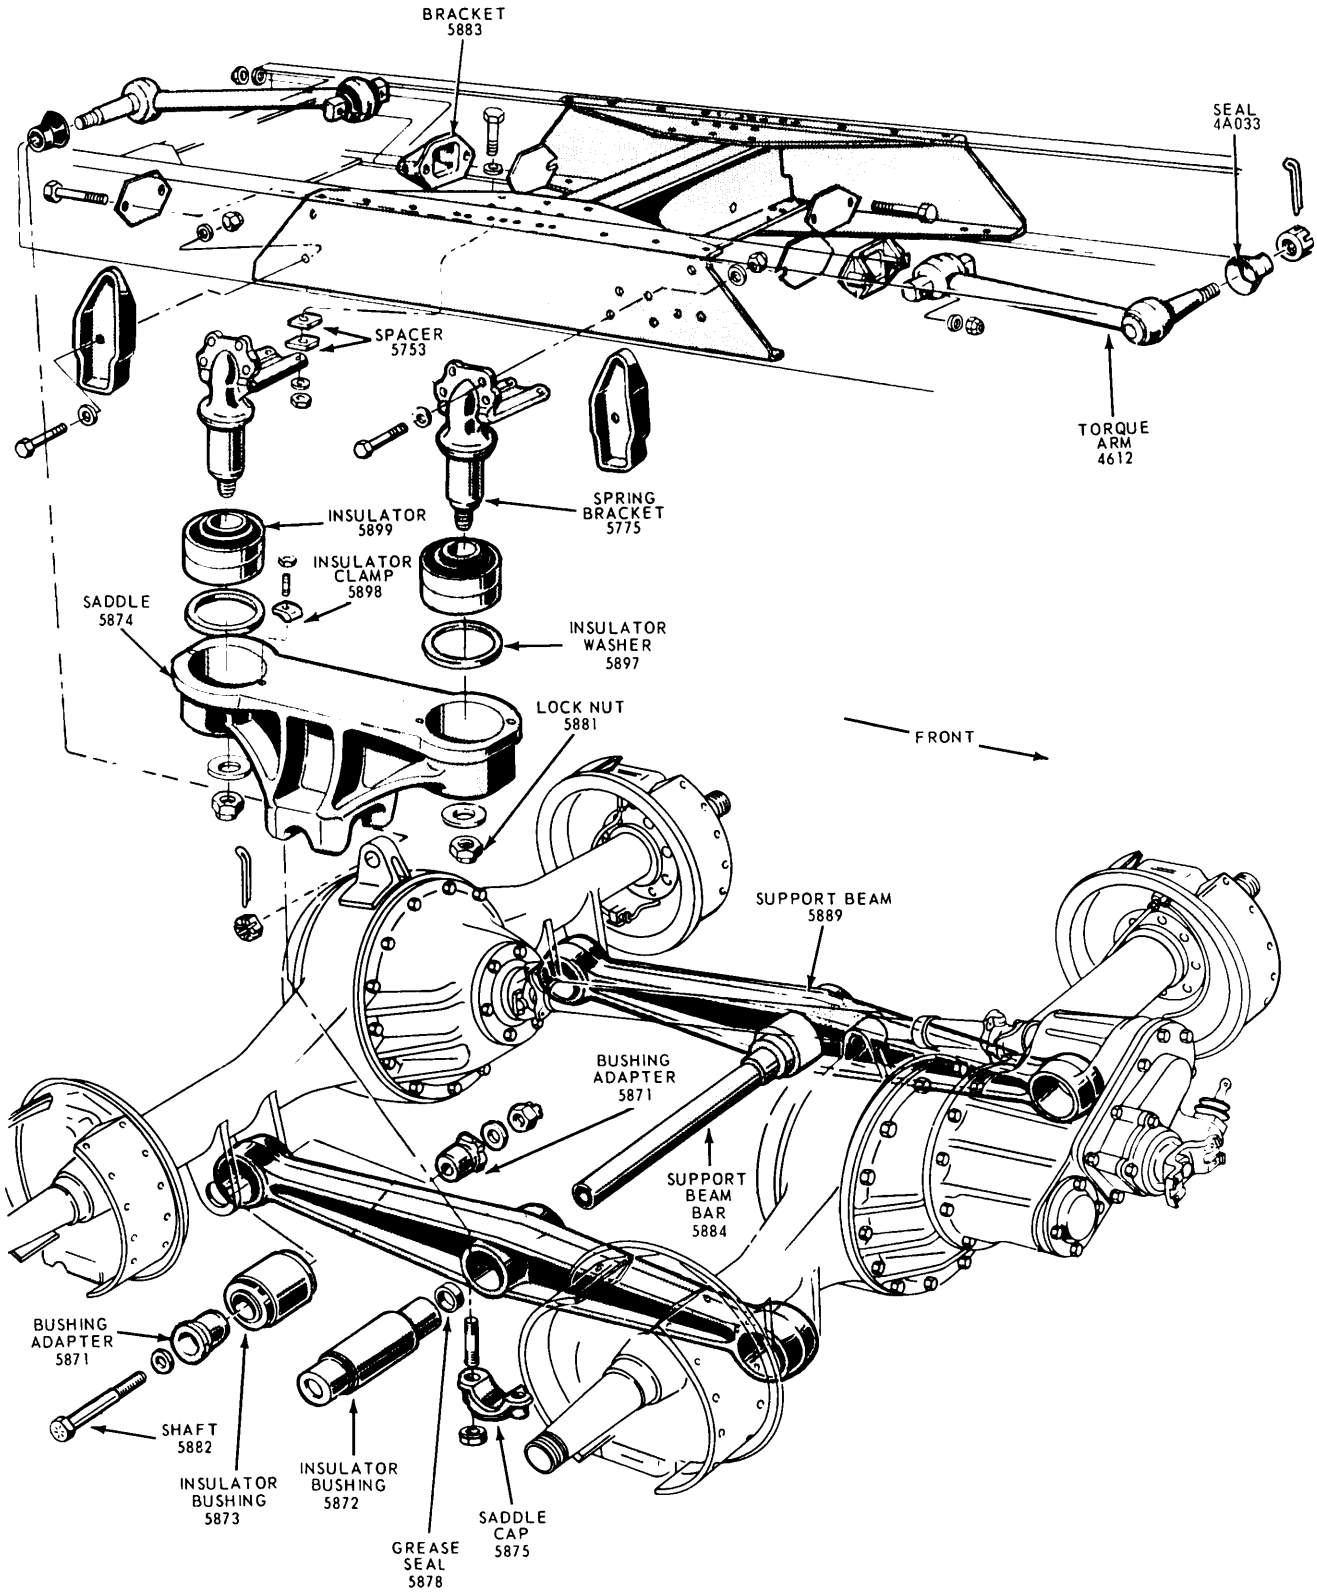

F 1303-A

FIG. 2 SR Tandem Suspension

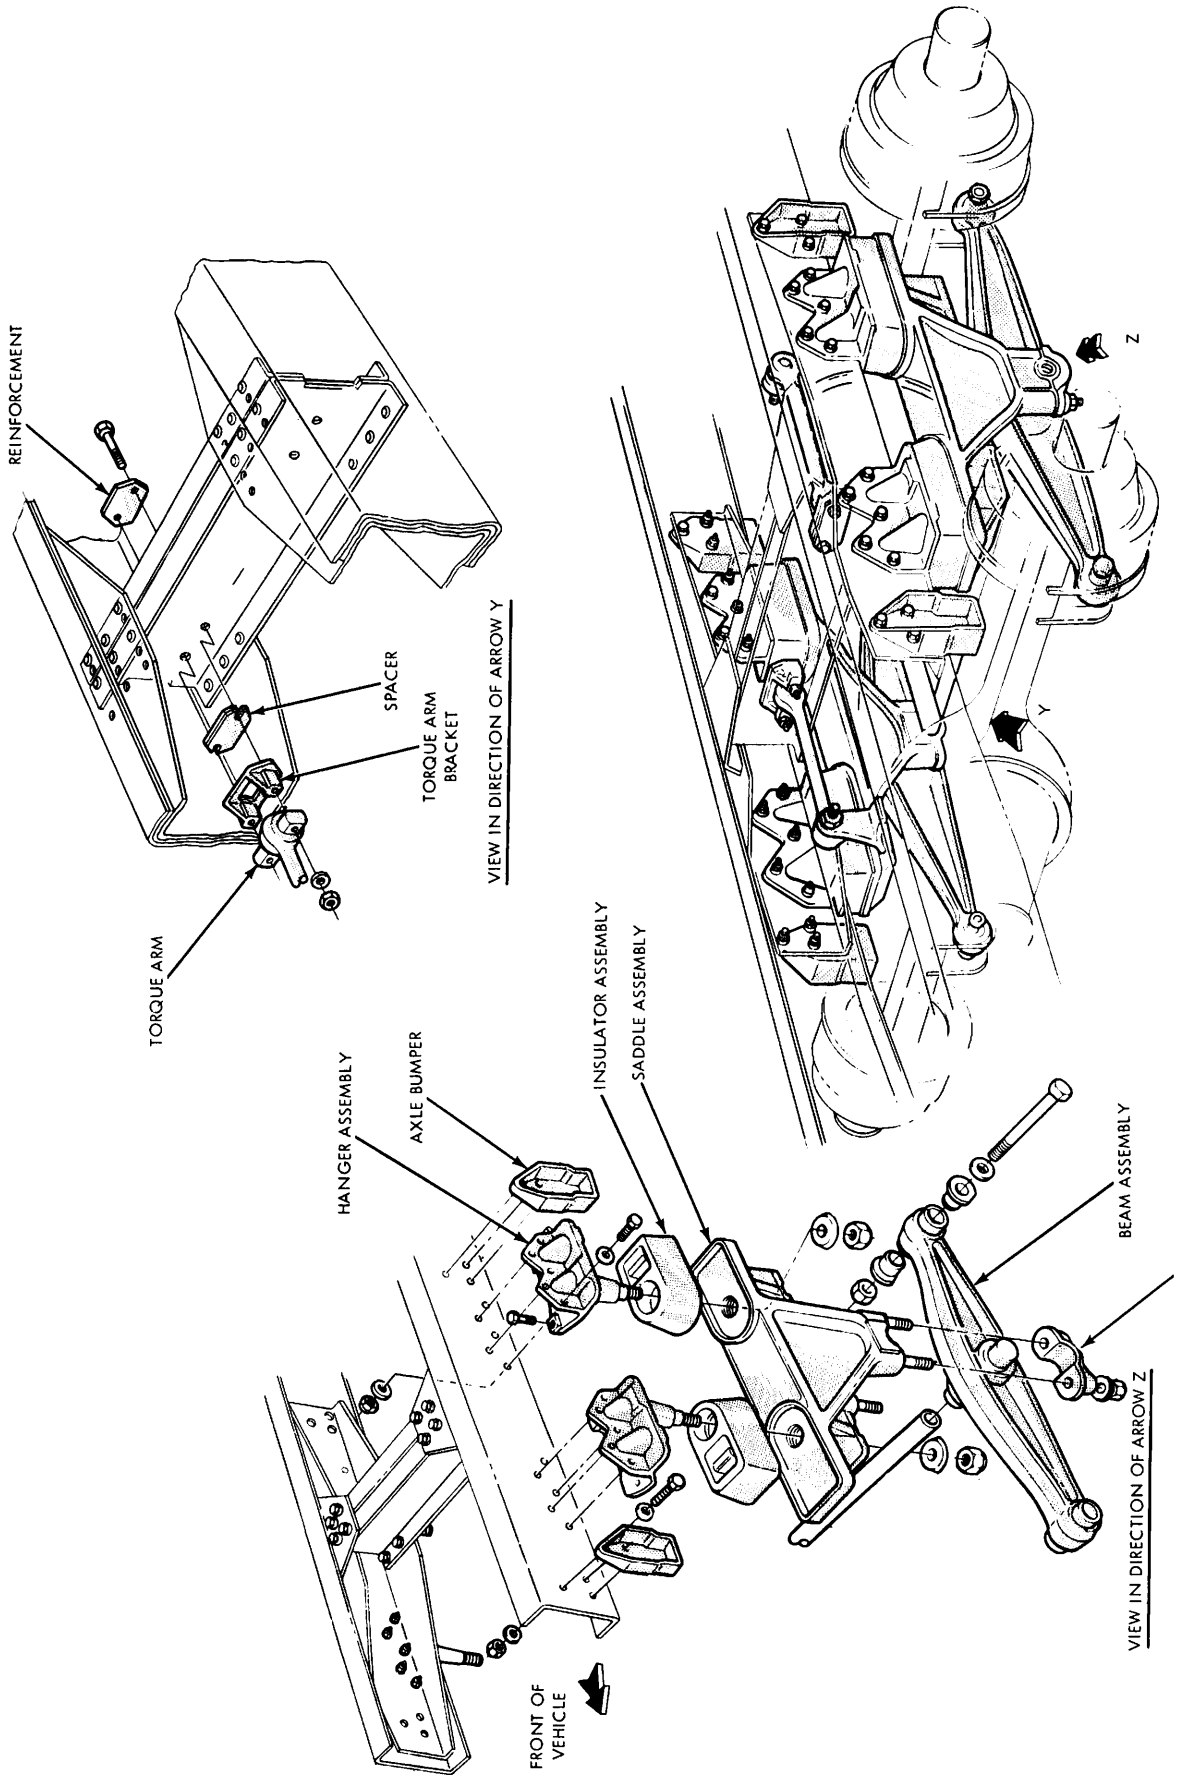

FIG. 3 RS Tandem Suspension

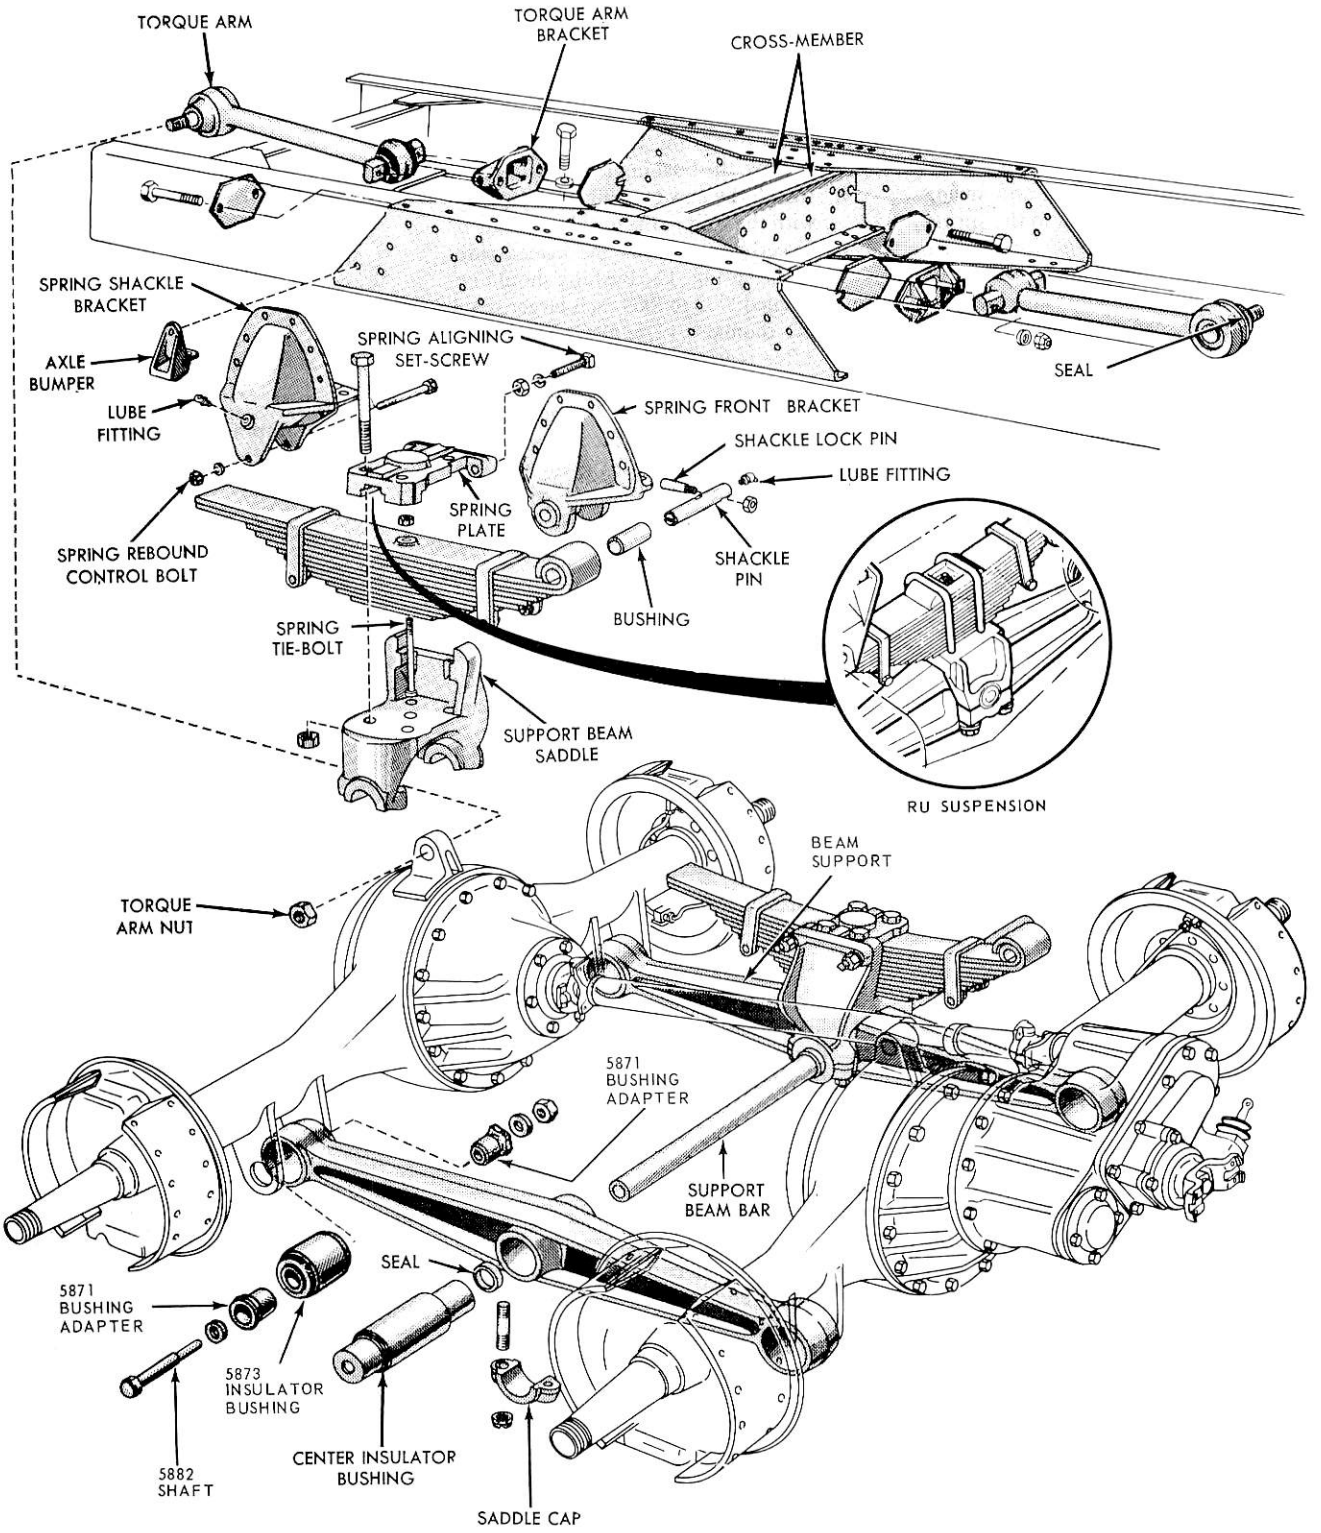

FIG. 4 RT Tandem Suspension Typical of RU Suspension

spring and install the U-bolts and nuts. Torque the nuts to specification.
10. RT Suspension Only—Position the spring plate and saddle to the spring and install the attaching bolts and nuts. Torque the nuts and bolts to specification.
11. Position the spring and saddle to the support beam and spring rear bracket.
12. Raise the support beam and spring and position the spring to the spring front bracket.
13. Align the spring with the front bracket and install the shackle pin.
14. Install the shackle pin lock pin and torque the lock pin nut to specification.
15. Install the hub and drum and wheels on the forward rear axle.
16. Remove the jack from the support beam and the blocks from the rear of the frame. Lower the saddle on the support beam bar center insulator bushing and install the saddle caps.
17. Install the saddle caps and torque the nuts to specification. **The weight of the vehicle must be on the suspension when the saddle cap attaching nuts are tightened.**

REAR SPRING FRONT SHACKLE PIN

RU, RUE AND RT SUSPENSIONS

Removal and Installation

1. Raise the vehicle frame and place safety stands under the frame.
2. Remove the shackle lock pin from the spring front bracket (Figs. 1 and 4).
3. Remove the lubrication fitting from the shackle pin and remove the shackle pin from the spring and spring bracket.
4. Position the shackle pin to the spring bracket. Align the spring with the shackle pin and install the pin.
5. Install the shackle lock pin and attaching nut and torque the nut to specification.
6. Install the shackle pin lubrication fitting and lubricate the pin.
7. Remove the safety stands and lower the vehicle.

SPRING BUSHING

RU, RUE AND RT SUSPENSIONS

Removal and Installation

1. Position the vehicle so that the rear of the frame may be raised with a chain hoist until the load is removed from the spring.
2. Remove the shackle lock pin which secures the spring shackle pin in the spring front bracket (Figs. 1 and 4). Remove the lubrication fitting from the bracket pin. Remove the pin from the bracket and spring bushing.
3. Raise the rear of the vehicle until the bushing clears the bracket. Install a bushing puller to remove the bushing from the spring, then remove the bushing from the puller.
4. Install the new bushing in the spring with the split in the bushing installed directly opposite to the loaded side of the spring. The bushing should be reamed .002 to .009 inch larger than the diameter of a new spring pin. After reaming, clean the bushing.
5. Lower the vehicle frame until the spring bushing is aligned in the bracket pin and lock it in place with the lock pin. Install the lubrication fitting in the bracket pin and lubricate the pin with chassis lubricant.

SUPPORT BEAM

Removal and Installation

1. Raise the rear of the vehicle and position safety stands under the rear end of the frame.
2. Remove the axle shafts from both rear axles.
3. Back off the brake adjustment at both wheels.
4. Remove the wheel and drum assemblies from both axles with a wheel dolly.
5. Disconnect the brake air lines from the brake actuators.
6. Remove the backing plate attaching bolts and nuts and remove the backing plates from both axles.
7. Position a jack under each axle housing.
8. Remove the saddle cap attaching nuts and remove the saddle caps.
9. On RU suspensions only: Cut the center of the support beam bar near the bushings and remove the center section of the bar. **Caution must be used if any burning is done during this operation as some of these beams are aluminum and some are nodular iron. These metals can easily become brittle with heat at quite low temperatures. The forged steel beam is not as sensitive.**
10. Position a jack under the center of the support beam and separate the beam ends from the axles.

Two types of beam end attachments are used (Fig. 5). Removal of the two types is as follows:

Tube type—The tube can be removed by removing the nuts and placing a spacer bushing between one

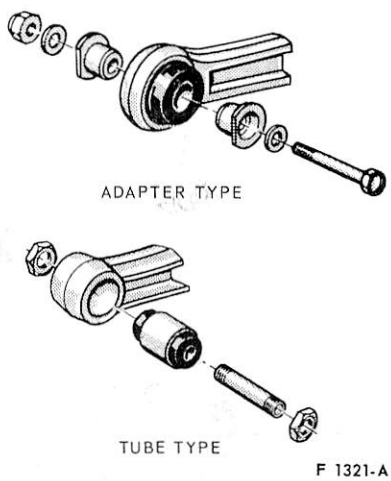

FIG. 5 Beam End Attaching Methods

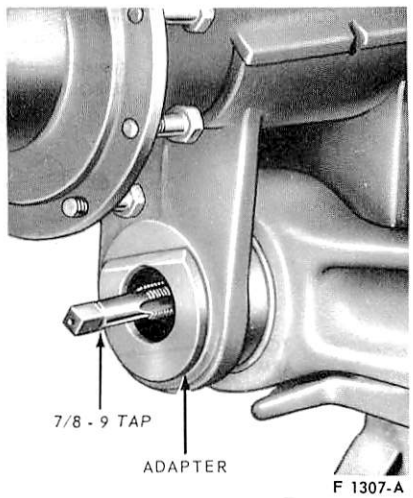

FIG. 6 Threading the Beam

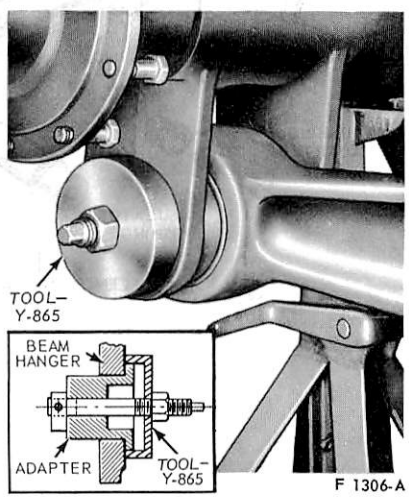

FIG. 7 Removing Beam Adapter

nut and the beam hanger. Then, tighten the nut to pull the tube loose. Another method is to saw through the tube along the inside surface of the beam hanger with a hack saw.

Adapter type—Remove the adapter bolt and nut. Then, thread the beam adapter with a 7/8-9 tap (Fig. 6).

Install puller tool OTCY865 in the adapter and remove the adapter from the axle and support beam (Fig. 7).

Remove the other adapter from the axle and support beam with a hammer and drift.

11. On RU suspensions, remove the beam from the vehicle. On SR and RT suspensions, pull the beam away from the vehicle and support beam bar.
12. After cleaning, coat the beam end openings and the outside of the bushings with ball joint grease. Then, install the bushings in the beam (Figs. 8 and 9).
13. On SR and RT suspensions, if installing a new beam, it may be necessary to weld the end cap on the center bushing.
14. Raise brackets. Attach the beam to the axles as follows:

Tube type—Apply a thin coat of ball joint grease to the tube. Insert the tube through the beam hanger and beam end bushing. Apply SAE-20 oil to the tube threads and install the nuts (one on each end of the tube). When both ends of the beam are attached to the axles, torque the tube nuts to specification (at the end of this Part).

Adapter type—Apply a thin coat of ball joint grease to the outside surface of the adapters and the ID of the bushings. Install the adapters through the beam hanger and into the beam end bushing. **The flats on the adapters must be in a vertical position (Fig. 5). Install the bolt, washers, and nut. Apply SAE-20 oil to the bolt threads. A washer must be under both the bolt head and the nut.** When both ends of the beam are attached to the axles, torque the nut to specification (at the end of this Part).

15. Position the brake backing plates to the axles and install the attaching bolts. Torque the bolts to specification.
16. Connect the air brake lines to the brake actuators.
17. Install the wheel and drum assemblies on the axles and install the axle shafts.
18. Adjust the brakes and lower the vehicle, aligning the support beam saddle with the center insulator bushing.
19. Install the saddle caps and torque the attaching nuts to specification. **The weight of the vehicle must be on the wheels when the saddle caps are tightened.**

EQUALIZING BEAM—RT 441 AND RT 444 SUSPENSIONS

After new ball sockets are pressed into the equalizing beams, the sockets must be counterbored prior to installing the washers and bolts. Use a 1 1/8 inch cutter and counterbore to a depth of 3/32 inch; then, insert four 1 inch washers top and bottom on both ends of the beam as shown in Figure 10. Install the bolts and lock nuts and torque to 45-50 ft-lb.

SADDLE AND/OR BUSHINGS

SR SUSPENSION (RS TANDEM SUSPENSION SIMILAR)

Removal and Installation

1. Raise the rear of the vehicle and position safety stands under the rear end of the frame.
2. Remove the axle shafts from both rear axles.
3. Back off the brake adjustment at both wheels.
4. Remove the wheel and drum assemblies from both axles with a wheel dolly.
5. Position jacks under the beam to support the beam and remove the saddle caps.
6. Lower the beam and remove the spring bracket to saddle attaching nuts (Fig. 2).
7. Lower the saddle on the beam and remove the saddle and insulators from the vehicle.
8. Remove the saddle insulator bushing retainer clamps.
9. Place the saddle in an arbor press and remove the bushings with Tool T57L-4614-A.
10. Clean the saddle bushing bores with solvent and remove any burrs.
11. Lubricate the bushings and saddle bore with ball joint grease C1AZ-19590-B and install them in the saddle with the washer first in the bore.
12. Install the bushing retainer clamps and torque the nuts to specification.
13. Position the saddle to the spring brackets (Fig. 2) and install the washers and attaching nuts. Torque the nuts to specification.
14. Raise the beam to seat the saddle over the beam and install the wheel and drum assemblies.
15. Adjust the brakes and install both axle shafts.
16. Lower the vehicle (be sure the saddle is seated on the support beam bushing) and install the saddle caps. Torque the nuts to specification with the weight of the vehicle on the wheels.

SUPPORT BEAM BUSHING AND/OR BAR

Removal and Installation

1. Remove the two saddle caps from each support beam.
2. Raise the vehicle frame and place safety stands under the frame.
3. Place a jack between the support beam and the spring or saddle and force the support beam down from the saddle until the bushings clean the saddle.
4. RU Series—Cut the support beam bar near each support beam bar bushing and remove the center section of the support beam bar. **Caution must be used if any burning is done during this operation as some of these beams are aluminum and some are modular iron. These metals can easily become brittle with heat at quite low temperatures. The forged steel beam is not as sensitive.**
5. All except RU Series—Cut the outside end off each support beam bushing. Observe the caution in step 4. Then, remove the support beams and bushings.
6. Position the puller tool shown in Fig. 9 and remove the bushing from each beam.
7. Lubricate the outside of each bushing and the bushing bore in each beam with white lead.
8. Install the bushings in the beams with the tools shown in Fig. 9. Then, remove the tools.
9. Install a new support beam bar in the bushings. Lubricate the bar end and bushing ID with ball joint grease C1AZ-19590-B. All except RU Series. Install the bushing end caps and weld the caps in the bushings.
10. Raise the axles so that the saddles rest on the support beam bushings and remove the safety stands from under the vehicle.
11. Lower the axles and check the alignment of the saddles on the bushings. Install the saddle caps and torque the attaching nuts to specification. **The axles must be in the operation position when the saddle caps are tightened.**

SUPPORT BEAM END BUSHING

Removal and Installation

1. Raise the rear of the vehicle and

place support blocks under the frame behind the rear axle.
2. Remove the axle shafts and back-off the brake adjustment.
3. Remove the wheel and drum from the truck with a wheel dolly.
4. Disconnect the brake air line from the actuator.
5. Remove the backing plate attaching nuts and bolts and remove the backing plate.
6. Position jacks under both axle housings and separate the beam end from the axle hanger.

Two types of beam end attachments are used (Fig. 5). Removal of the two types is as follows:

Tube type—The tube can be removed by removing the nuts and placing a spacer bushing between one nut and the beam hanger. Then, tighten the nut to pull the tube loose. Another method is to saw through the tube along the inside surface of the beam hanger with a hack saw.

Adapter type—Remove the adapter bolt and nut. Then, thread the beam adapter with a 7/8-9 tap (Fig. 6).

Install puller Tool OTCY865 in the adapter and remove the adapter from the axle and support beam (Fig. 7).

Remove the other adapter from the axle and support beam with a hammer and drift.

7. Place a jack between the support beam and the end of the spring and fork the beam down to clear the hanger bracket on the axle (Fig. 11).
8. Trim the rubber from the bushing on the inboard side of the support beam.
9. Position the tool OTC KIT Y850A to the beam and bushing and remove the bushing from the support beam (Fig. 8).
10. Lubricate the beam opening and the bushing with white lead.
11. Position the bushing to the beam and install the bushing in the beam with the tools shown in Fig. 8.
12. Remove the bushing tools from the beam and remove the jack between the beam and spring or saddle.
13. Position the beam to the axles. Attach the beam to the axle as follows:

Tube type—Apply a thin coat of ball joint grease C1AZ-19590-B to he tube. Insert the tube through the beam hanger and beam end bushing. Apply SAE-20 oil to the tube threads and install the nuts (one on each end of the tube). When both ends of the beam are attached to the axles, torque the tube nuts to specification (at the end of this Part).

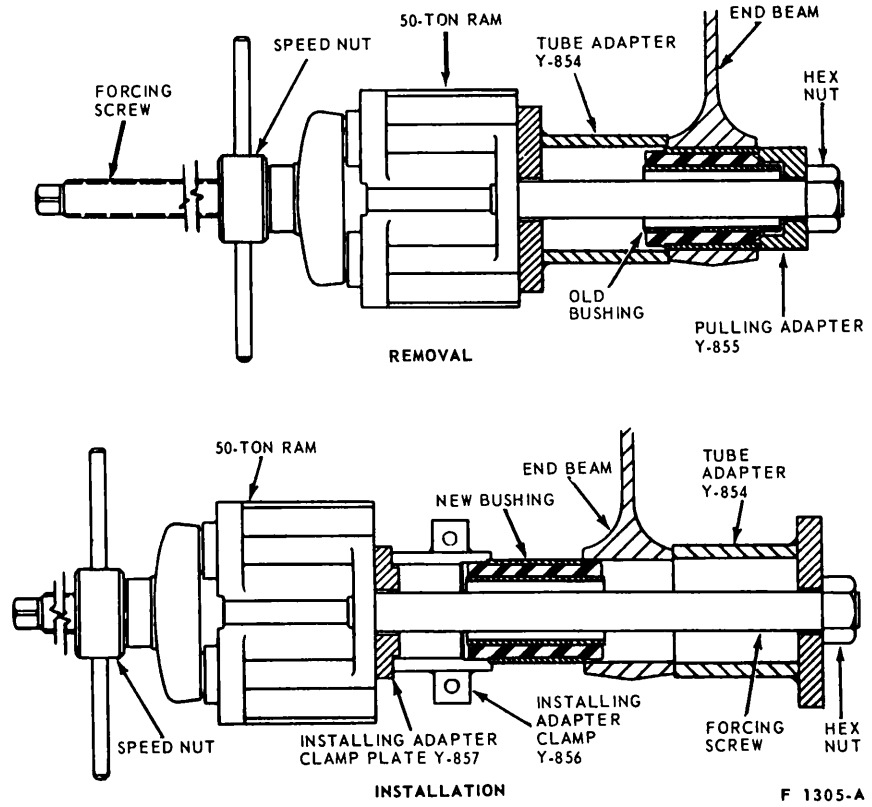

FIG. 8 Beam End Bushing Tools

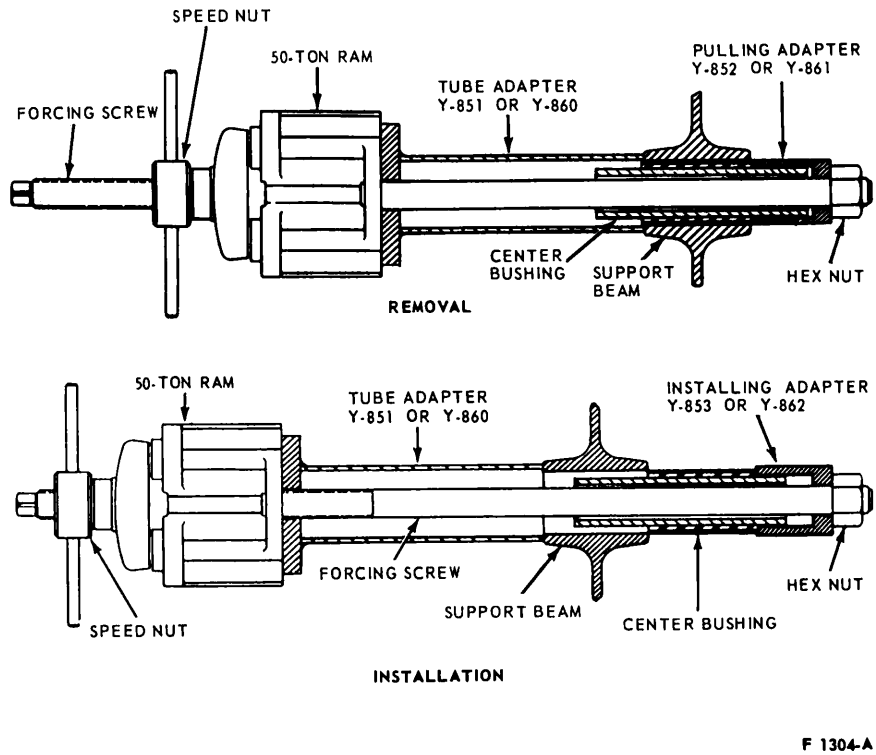

FIG. 9 Beam Center Bushing Tools

Adapter type—Apply a thin coat of ball joint grease C1AZ-19590-B to the outside surface of the adapters and the inside diameter of the bushing. Install the adapters through the beam hanger and into the beam end bushing. **The flats on the adapters must be in a vertical position (Fig. 5). Install the bolt, washers, and nut. A washer must be under both the bolt head and the nut.** When both ends of the beam are attached to the axles, torque the nut to specification (at the end of this Part).

14. Position the brake backing plate to the axle and install the attaching bolts and nuts. Torque the nuts to specification.
15. Connect the brake air line to the actuator.
16. Install the wheel and hub and drum on the axle and install the axle shaft.
17. Adjust the brakes and lower the vehicle.

TORQUE ARM

Removal and Installation

1. Remove the cotter pin from the torque arm stud at the axle bracket if so equipped.
2. Remove the castellated or lock nut attaching the torque arm stud to the axle bracket.
3. Position a jack under the differential carrier to prevent the axle from tipping.
4. Push the torque arm stud from the axle bracket with Tool OTC1002-L.
5. Remove two nuts attaching the torque arm bracket to the frame crossmember and remove the torque arm and bracket from the vehicle.
6. Position the torque arm and the torque arm bracket to the frame crossmember and install the attaching nuts. Torque the nuts to specification.
7. Position the torque arm to the axle bracket and install the attaching nut. Torque the nut to specification and install the cotter pin if a castellated nut is used.
8. Remove the jack from under the differential carrier.

DESCRIPTION

REAR SUSPENSION—TANDEM

This suspension has four conventional stacked leaf springs. The eccentric bushings of the torque leaves assure more positive axle spacing. Rubber pads in the rear spring hangers absorb spring shocks when the vehicle is driven unloaded. See Fig. 1.

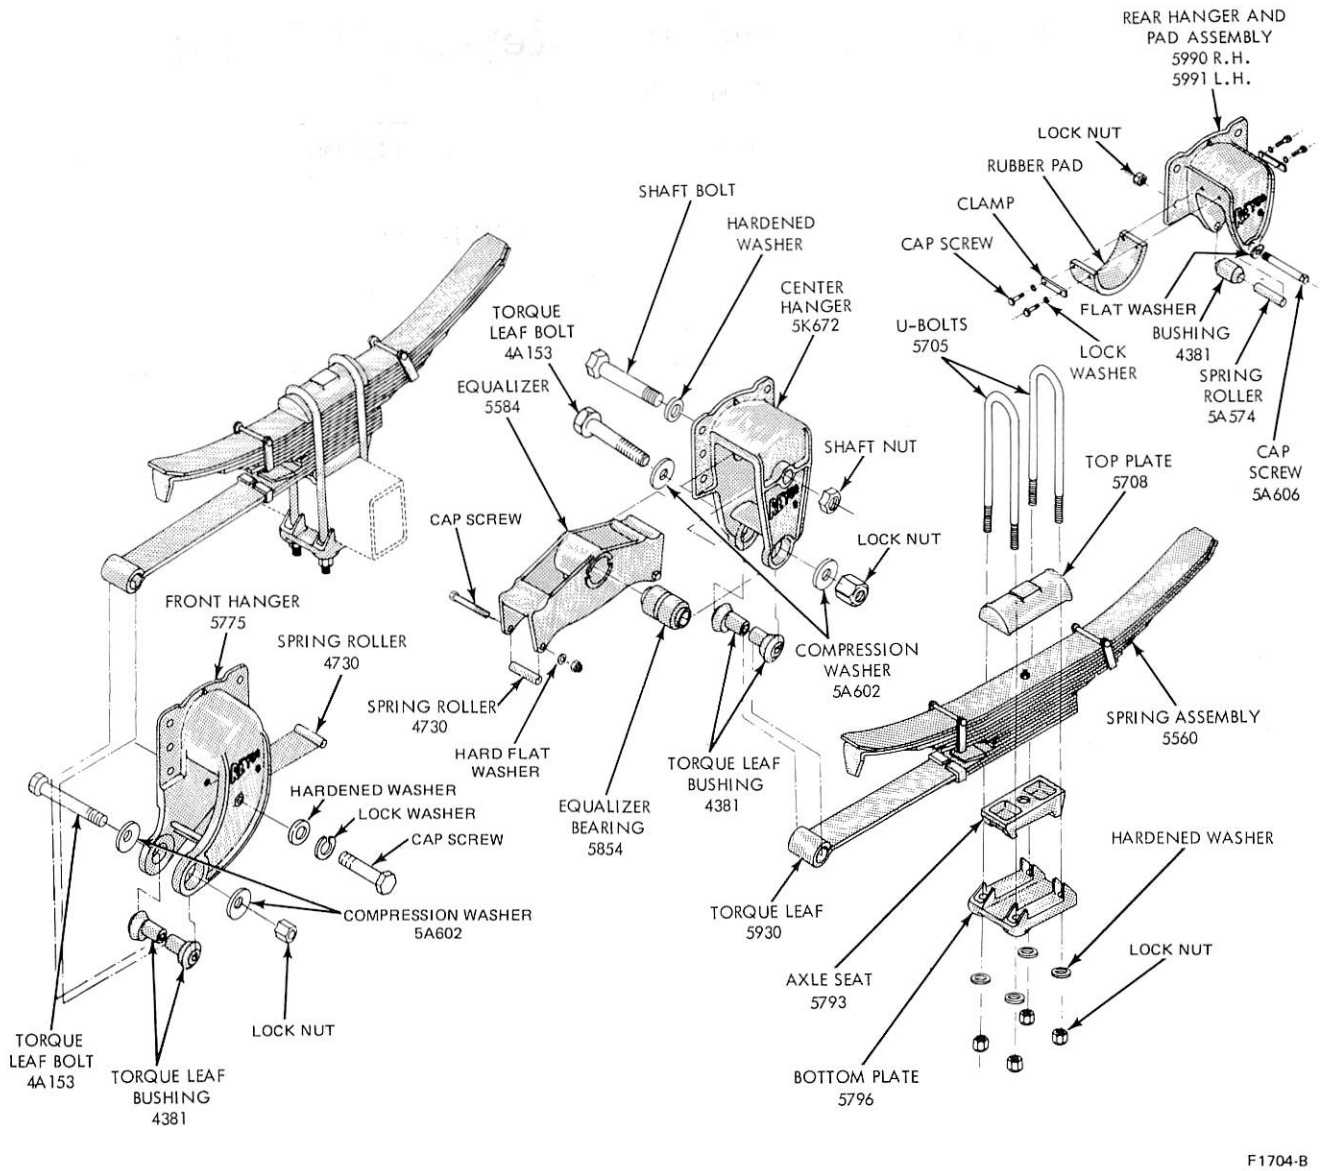

FIG. 1 Reyco 101 Tandem Suspension—Disassembled

ADJUSTMENTS

REAR AXLE TO FRAME

1. Determine a point on the frame rail that will permit clearance for measuring device to contact the frame and run perpendicular. This must be done on both sides of the vehicle (the distance is optional but must be the same on both sides). See Fig. 2.
2. To set one of the rear axles perpendicular to the frame rail, attach a string (or cord) to some object behind the rear axle (the brake chamber air line, for example).
3. Position two 1 x 2 x 2 inch blocks on the rear wheel rim bead, one on the forward side of the rim and one on the rear side.
4. Draw the string around behind the tire across the tread at approximately axle center point.
5. Pull the string tight and aligned so it just contacts both the rearward and forward blocks.
6. Keeping the string in this position (just contacting the blocks), move to the position on the frame rail determined in Step 1.
7. Record distance A.
8. Repeat the procedure on the other side of the vehicle.
9. Move the truck to permit the wheels to rotate 180 degrees and again record the readings on both sides. This will determine the existence of a bent wheel.
10. If the readings differ, the bent wheel should be replaced. If the readings are the same, proceed with the axle alignment.
11. The two distances A (left and right sides) should be the same. If they are not the same, the rear drive axle housing should be adjusted by loosening the eccentric bolt nuts and rotating the bolt to reposition the axle housing (Fig. 3). This should be done to acquire equal distances at A (Fig. 2).

FRONT DRIVE AXLE TO REAR DRIVE AXLE

1. After the rear axle is adjusted perpendicular to the frame, the forward drive axle should be set parallel to the rear drive axle.
2. A deep center-to-center trammel bar should be used to check the distances on both sides of the vehicle.
3. If the distance is not the same on both sides (and within the 50 inch plus or minus 1/8 inch specification), the eccentric bolt on the forward drive axle suspension should be adjusted to acquire an equal distance between axle centers on both sides.

ECCENTRIC BOLT

1. The vehicle should always be on a level floor area when performing either of the alignment procedures.
2. The vehicle (under power) should be rocked back and forth several times to free up and center all suspension joints.
3. Loosen the nut on the torque bolt approximately three full turns and tap the end of the torque bolt. Also tap the end of the spring behind the front hanger casting.
4. To adjust, place a wrench on the torque bolt. Place the vehicle in drive with the brakes engaged and gently disengage the clutch. The torque bolt will move with ease to the desired point.
5. Remember that the bolt is turned in the opposite direction to the desired movement of the axle.
6. The maximum adjustment is 7/16 inch on each side of the axle. Care should be taken to determine just how far the bolt should be turned to obtain the desired movement.
7. After adjusting, torque the radius leaf locknut to 150-205 ft-lb.

ADJUSTMENTS

Certain rear axle and drive line trouble symptoms are also common to the engine, transmission, wheel bearing, tires, and other parts of the vehicle. For this reason, be sure that the cause of the trouble is in the rear axle before adjusting, repairing or replacing any of the parts. Reference to the Truck Diagnosis Manual can be very helpful.

On F-100 through F-350 vehicles, certain trouble symptoms may be caused by limited-slip differentials. To determine whether these vehicles are equipped with conventional or limited-slip differentials, check the vehicle rating plate and the axle ratio tag.

Location of the axle Identification Code on the Rating Plate is shown in Fig. 1. Refer to specifications for a complete listing.

TOOTH CONTACT PATTERN CHECK (ALL EXCEPT FORD)

Paint the gear teeth and roll a pattern as described in Adjustments. After diagnosing the tooth pattern as described here, make the appropriate adjustments.

The correct tooth contact pattern is considered to be the final check on pinion depth and backlash adjustments. Backlash adjustments, however, must be within the limits given in Fig. 10.

Fig. 2 shows typical Dana patterns, and Fig. 3 shows typical Eaton and Rockwell patterns.

Due to minor differences existing between individual gear sets, these patterns should be considered as typical only and should be used as a guide rather than a rigid standard. The drive pattern is rolled on the convex side of

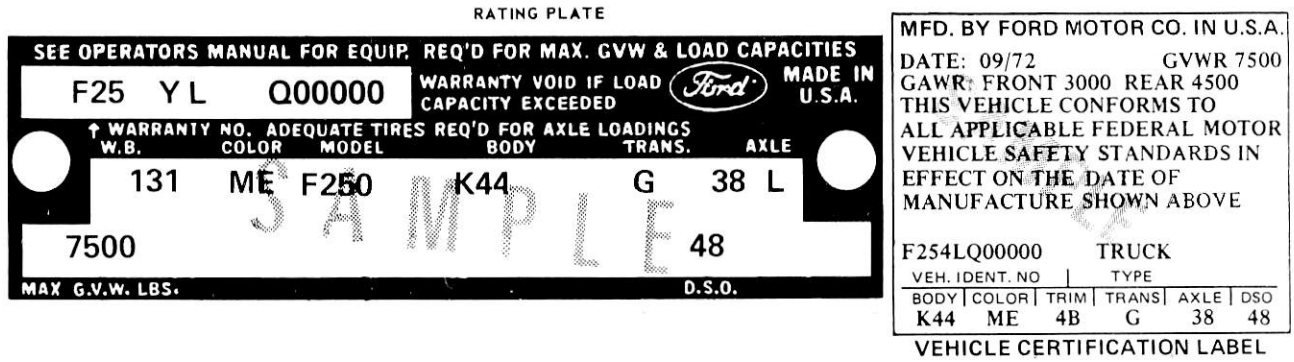

FIG. 1 Truck Rating Plate—Rear Axle Code Location

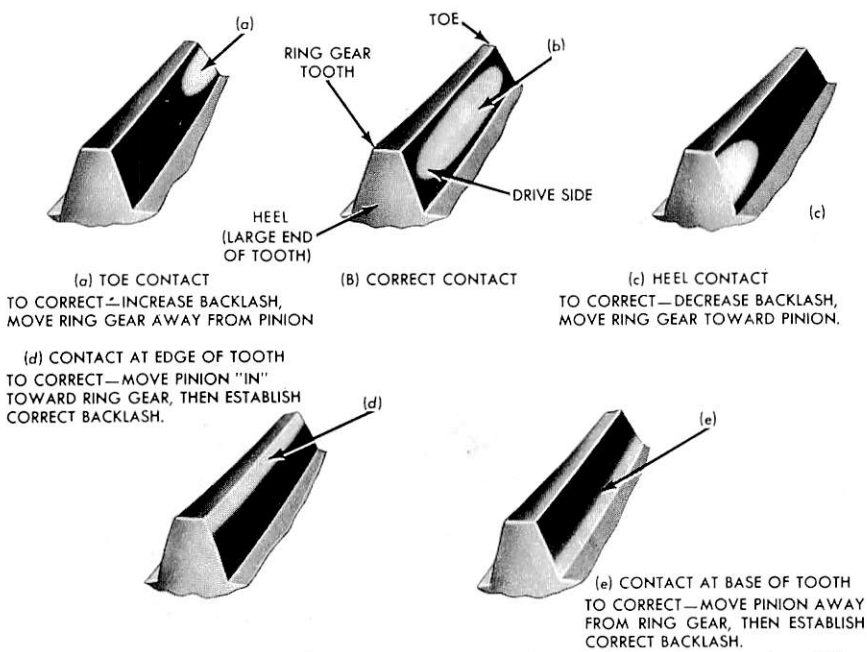

NOTE: *Contact patterns (a), (c), (d) and (e) indicate* ***Incorrect*** *placement of shims and will result in noise and gear failure. Pattern (b) shows* ***Correct*** *contact pattern. The above ring gear tooth contact patterns would be made under* ***Load*** *conditions only (actual operation). E 1730-A

FIG. 2 Typical Gear Tooth Contact Patterns—Dana

the tooth, and the coast pattern is rolled on the concave side.

In general, desirable tooth patterns should have the following characteristics:

1. The drive pattern should be fairly well centered on the tooth.
2. The coast pattern should be centered on the tooth but may be slightly toward the toe.
3. Some clearance between the pattern and the top of the tooth is desirable.
4. There should be no hard lines where the pressure is high.

The pattern movements with changes in backlash and pinion depth are typical of all axle gears, hypoid or spiral bevel.

The movement of tooth contact patterns can be summarized as follows:

a. Decreasing backlash moved the ring gear closer to the pinion:

Drive pattern (convex side of gear) moves slightly lower and toward the toe.

Coast pattern (concave side of gear) moves lower and toward the toe.

b. Increasing backlash moves the ring gear away from the pinion.

Drive pattern moves slightly higher and toward the heel.

Coast pattern moves higher and toward the heel.

c. Thinner shim with the backlash constant moves the pinion closer to the ring gear:

Drive pattern moves deeper on the tooth (flank contact) and slightly toward the toe.

Coast pattern moves deeper on the tooth and toward the heel.

d. Thicker shim with the backlash constant moves the pinion further from the ring gear:

Drive pattern moves toward the top of the tooth (face contact) and toward the heel.

Coast pattern moves toward the top of the tooth and slightly toward the toe.

If the patterns are not correct, make the changes as indicated. The pinion need not be disassembled to change a shim.

GEAR TOOTH CONTACT PATTERN CHECK (FORD AXLES)

When rolling a tooth pattern, use the special compound (tube) packed with each service ring gear and pinion set.

Paint all gear teeth and roll a pattern as described in Adjustments. After diagnosing the tooth pattern as explained here, make the appropriate adjustments. If making a final gear tooth contact pattern check, it is

necessary to recognize the fact that there are three different types of gear set, hunting, non-hunting and partial non-hunting. Each type is determined by the number of teeth in the gears. The non-hunting and partial non-hunting types can be identified by the paint timing marks on the pinion and ring gear teeth.

ACCEPTABLE TOOTH PATTERNS (FORD AXLES)

Figure 4 shows acceptable tooth patterns all for axles. Any combination of drive and coast patterns will be acceptable.

In general, acceptable tooth patterns should have the following characteristics:

1. The drive pattern should be fairly well centered on the tooth.
2. The coast pattern should be fairly well centered on the tooth.
3. Some clearance between the pattern and the top of the tooth is desirable.
4. There should be no hard lines where the pressure is high.

The individual gear set need not conform exactly to the ideal pattern in order to be acceptable. **Any combination of drive and coast patterns shown in Fig. 4 are acceptable.**

Hunting Gear Set

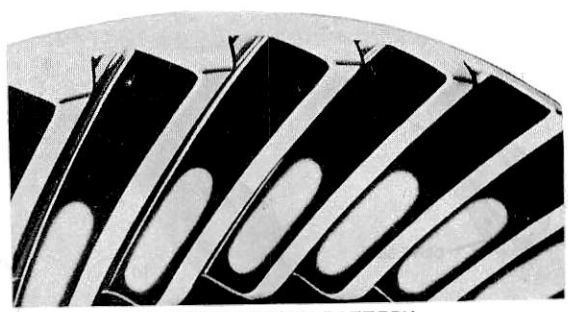
In a hunting-type gear set, any one pinion gear tooth comes into contact with all ring gear teeth. In this type, several revolutions of the ring gear are required to make all possible gear combinations.

Non-Hunting Gear Set

In a non-hunting type gear set, any one pinion gear tooth comes into contact with only a few ring gear teeth. In this type, only one revolution of the ring gear is required to make all possible tooth contact combinations. **Any combination of drive and coast patterns shown in Fig. 4 are acceptable.**

Partial Non-Hunting Gear Set

In a partial non-hunting type gear set, any one pinion tooth comes into contact with only part of the ring gear teeth, but more than one revolution of the ring gear is required to make all possible gear tooth combination. Any



CORRECT TOOTH PATTERN

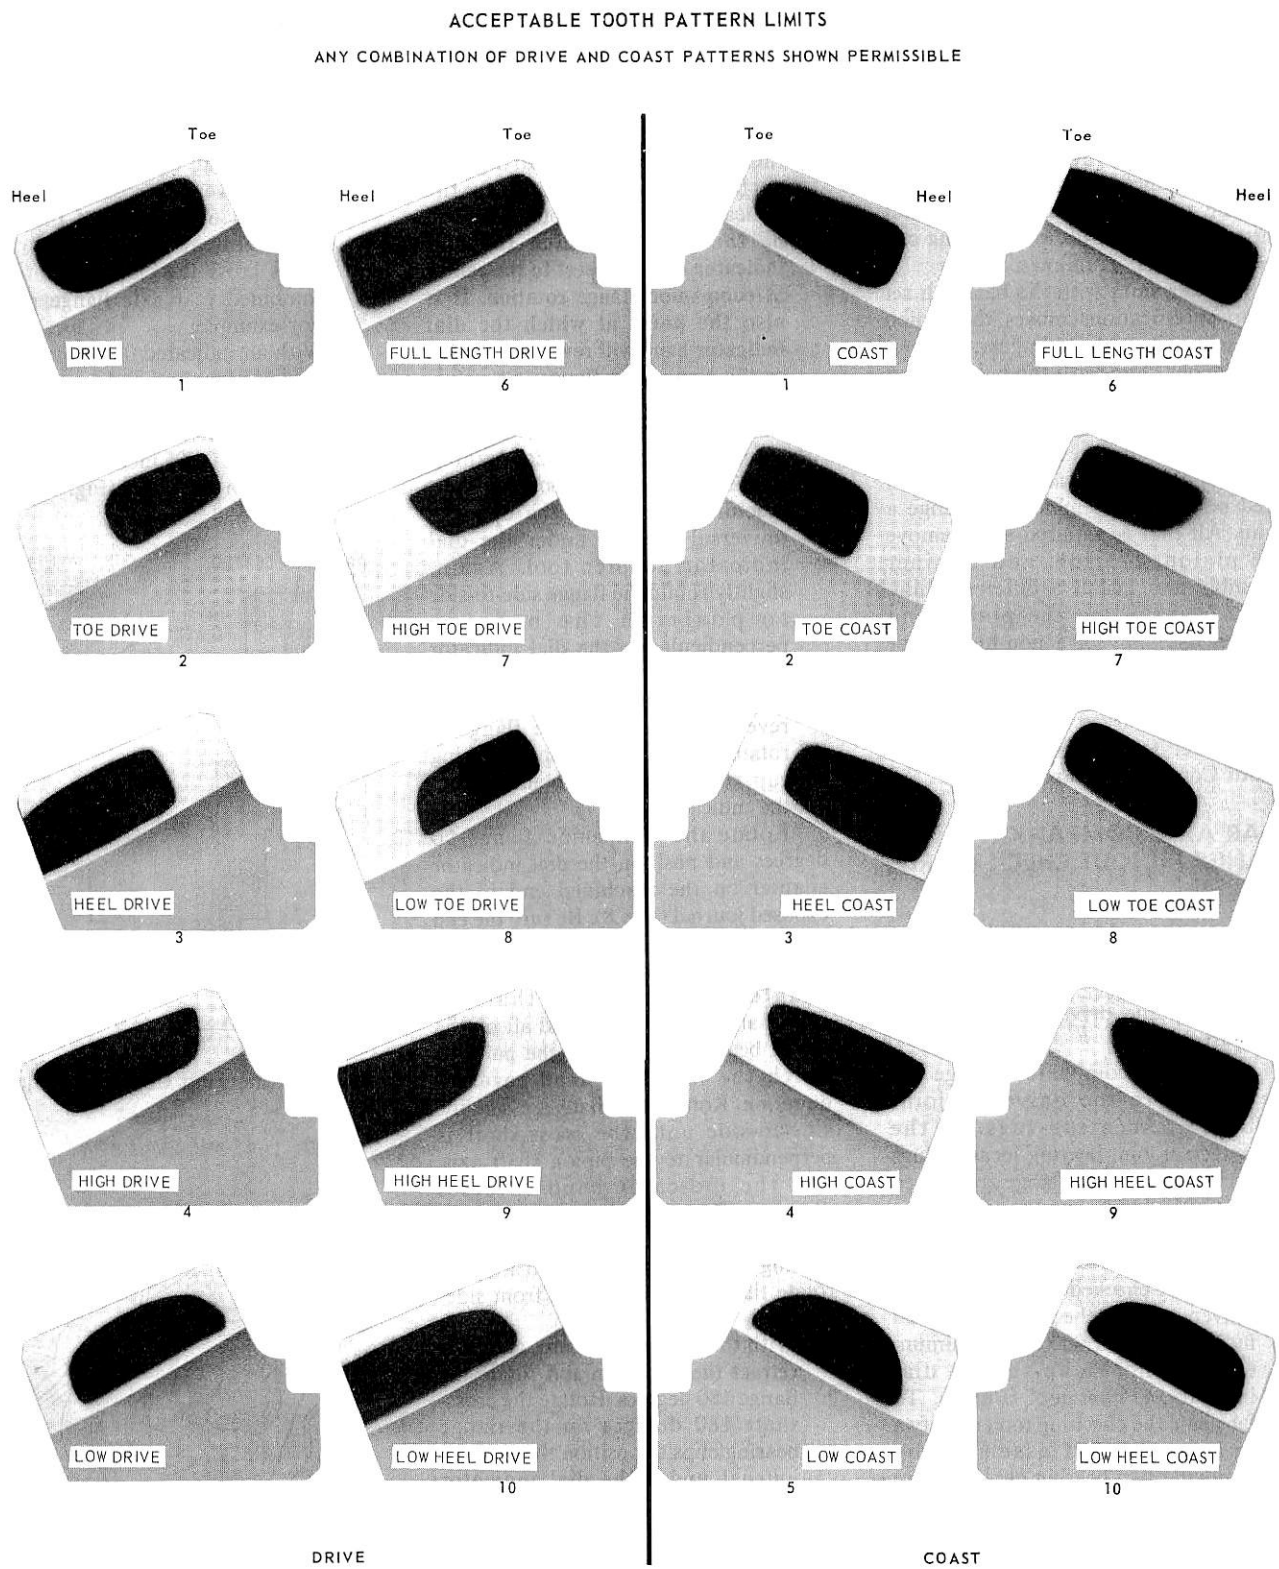
FIG. 3 Eaton and Rockwell Gear Tooth Contact Patterns



E 1680-A

FIG. 4 Typical Gear Tooth Contact Patterns—Ford

combination of drive and coast patterns shown in Fig. 4 are acceptable.

SHIM CHANGES

Since each gear set rolls a characteristic pattern, the patterns shown in Fig. 4 are considered acceptable and should be used as a guide. The drive pattern is rolled on the convex side of the tooth, and the coast pattern is rolled on the concave side.

The movement of tooth contact patterns with changes in shimming can be summarized as follows:

1. Thicker shim with the backlash set to specifications moves the pinion further from the ring gear.
2. Thinner shim with the backlash set to specifications moves the pinion closer to the ring gear.

If the patterns are not correct, make the changes as indicated. The pinion need not be disassembled to change a shim. All that is required is to remove the pinion, bearing, and retainer assembly and install a different shim. When reinstalling the pinion and retainer assembly of a non-hunting or partial non-hunting gear set, be sure that the marked tooth on the pinion indexes between the marked teeth on the ring gear. Refer to Pinion and Ring Gear Tooth Contact Adjustment.

REAR AXLE COMPANION FLANGE RUNOUT CHECK (FORD AXLES)

1. Raise the vehicle on a hoist that supports the rear axles (twin-post hoist).
2. Remove the drive shaft assembly (Part 15-60).
3. Check the companion flange for damage to the universal joint bearing locating lugs. If the universal joint bearing locating lugs on the companion flange are shaved (worn) or damaged, replace the companion flange (Fig. 5).
4. The rear axle companion flange runout is checked with a modified universal joint (checking tool) a dial indicator with 1.000 inch minimum travel, and a cup-shaped dial indicator adapter tool (Fig. 6). To fabricate the checking tool, modify a universal joint assembly by removing two bearing cups that are opposite each other, and cutting or grinding off one of the universal joint bearing flanges (Fig. 6).
5. Install the cup-shaped adapter on the dial indicator stem. Install the dial indicator on the pinion retainer or pinion nose bumper bracket. Position the indicator to allow an indication at the ends of the universal joint bearing cups and the remaining exposed journal of the cross-shaft.
6. Turn the companion flange so that the dial indicator cup-type adapter rests on the machined surface of the bearing cup (Fig. 6). Rotate the companion flange side-to-side slightly to obtain a reading indicating that the bearing cup surface is perpendicular to the indicator cup-type adapter. **This will be the point at which the dial indicator cup is closest to the center of companion flange rotation. It is also the point at which the dial indicator hand will reverse direction as the companion flange is turning.** Set the dial indicator to zero.
7. Carefully retract the dial indicator stem and rotate the companion flange 180 degrees to position the machined surface of the opposite universal bearing under the dial indicator adapter tool. Again, slightly rotate the flange side-to-side to position the bearing perpendicular to the dial indicator adapter. Again, this is the point at which the indicator hand will reverse direction as the flange is rotated. Record the flange bearing cup runout reading obtained from the indicator (Fig. 7).

Rotate the companion flange 90 degrees and position the dial indicator adapter on the machined end of the exposed journal (Fig. 8). **Be sure the end surface of the exposed journal is perpendicular to he indicator cup-type adapter.** This requires that the crossshaft be moved fore and aft on the flange bearing cups. **Note the point at which the indicator hand reverses direction.** Rotate the flange assembly side-to-side until the cross-shaft is perpendicular to the pinion shaft axis, and the indicator hand reverses direction. Zero, the dial indicator and check the zero point again by slightly moving the cross-shaft fore and aft, then rotate the companion flange from side-to-side.

8. With the indicator at zero, carefully retract the dial stem and rotate the flange 180 degrees. Rotate the cross-shaft 180 degrees on the flange bearing cups to position the exposed journal under the dial indicator adapter. Rock the cross-shaft fore and aft and the companion flange side-to-side to establish the point at which the indicator hand reverses direction. This will determine the drive shaft universal cross-shaft runout. Record this reading (Fig. 8).
9. **Repeat steps 5 through 8 at least three times and average the indicator readings obtained (Fig. 7).**
10. To determine the total (combined) companion flange runout, it will be necessary to use the combined runout chart (Fig. 9). Position a straight edge at the amount of flange bearing cup runout indicated on the left hand column of the chart. Position another straight edge vertically at the amount of drive shaft universal cross-shaft runout indicated on the top of the chart. The point at which the straight edges cross the chart indicates the combined rear axle flange runout. For example:

With an indicated 0.003 inch flange bearing cup runout and an indicated 0.004 inch universal cross-shaft runout (Fig. 8), the combined companion flange runout will be 0.005 inch as indicated in the square on the chart (Fig. 9).

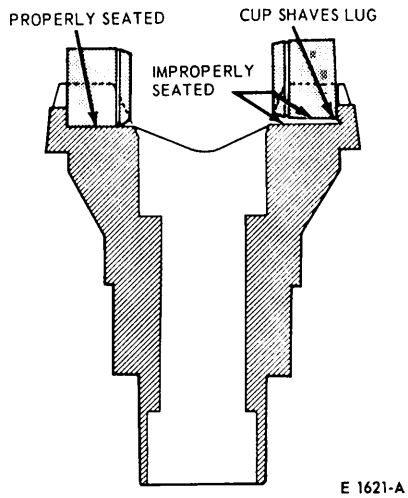


FIG. 5 Checking Companion Flange

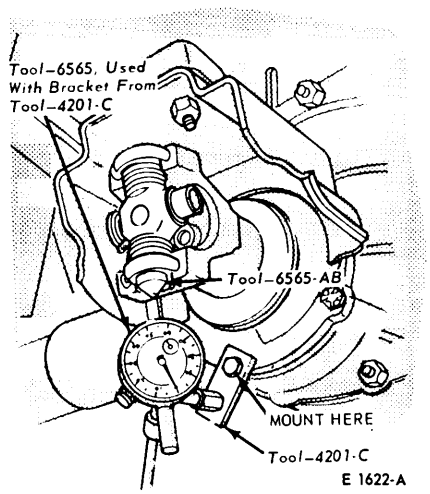

FIG. 6 Flange Bearing Cup Runout Check

11. If the reading obtained in Step 10 exceeds specifications, reposition the companion flange 180 degrees on the pinion shaft and repeat steps 1 through 11.
12. If the repeat readings still exceed specifications, reposition the flange an additional 90 degrees on the pinion shaft and check the runout (Steps 4 through 10).
13. If the runout is still excessive, replace the companion flange and check the runout. If necessary, rotate the new flange on the pinion shaft until an acceptable runout is obtained.

If excessive runout is still evident after replacement of the companion flange, it will be necessary to replace the ring and pinion gear, and repeat the above checks until runout is within specifications.

14. Install the drive shaft assembly (Part 15-60). **Make sure the universal joint bearing cups are properly positioned between the companion flange lugs.**
15. Lower the vehicle. Road test the vehicle. If drive shaft vibrations are evident during the road test, remove the drive shaft from the companion flange and rotate it 180 degrees. Road test the vehicle again.

REAR AXLE COMPANION FLANGE RUNOUT CHECK (DANA AXLES)

1. Raise the vehicle on a hoist that supports the rear axles (twin-post hoist).
2. Remove the drive shaft assembly (Part 15-60).
3. Check the companion flang for damage to the universal joint bearing locating lugs. If the universal joint bearing locating lugs on the companion flange are shaved (worn) or damaged, replace the companion flange (Fig. 5).
4. Install the drive shaft assembly (Part 15-60). Make sure the universal joint bearing cups are properly positioned between the companion flange lugs.
5. Lower the vehicle. Road test the vehicle. If drive shaft vibrations are evident during the road test, remove the drive shaft from the companion flange and rotate it 180 degrees. Road test the vehicle again.

TANDEM INTER-AXLE DIFFERENTIAL VACUUM OPERATED LOCKOUT CONTROL-LEAKAGE TEST

Place the vehicle on level ground with the parking brake released and the transmission in neutral. Start the engine with the valve control knob pulled out (the power divider differential locked out).

Accelerate the engine for a few seconds, release the accelerator, and turn off the ignition switch. Immediately measure the distance between the face of the lockout cylinder mounting bracket and the center of the push rod yoke to the lever pin. Then after ten minutes, measure the distance again. If the distance has not increased, the system may be considered vacuum tight. However, if the distance has increased, a vacuum leak exists in the system. First check all the connections. After all the hoses and the pipe connections have been checked and tightened, test the system again. If the vacuum leaks still exist, check the control valve and check valve assembly, and the power divider lockout cylinder in the order given.

Indicator Reading	Flange Bearing Cup Runout—Inch	Driveshaft Universal Cross-Shaft Runout—Inch
1	0.004	0.005
2	0.002	0.004
3	0.003	0.003
Average	0.003	0.004

CE1943-A

FIG. 7 Flange Bearing Cup and Cross-Shaft (v2) Runout Averaging Chart—Typical Readings

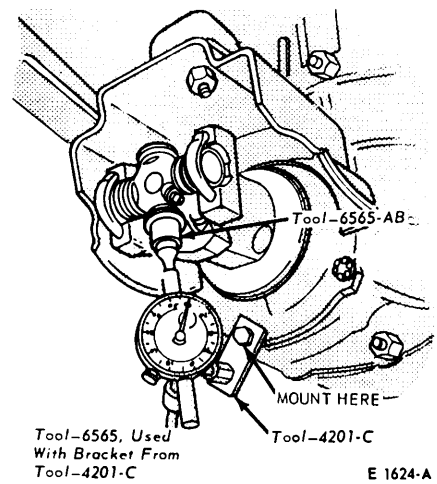

FIG. 8 Cross-Shaft Runout Check

EATON 2-SPEED TANDEM STRAIGHT-AIR SHIFT SYSTEM

A simple method for quickly locating troubles in the system can be accomplished by listening for possible air leaks and for sound which would indicate shift unit operation. Proceed as follows:

Turn ignition switch "ON" to energize and open solenoid valve. Move shifter knob to "HI". In this position, air pressure should be present in the entire system. Check for air leaks. With shifter knob in "LO", air pressure should be present only up to the shifter valve.

To check axle for shifting, operate shifter knob back and forth from "LO" to "HI". If the shift unit is operating, a definite reaction will be evident by sound of parts movement.

If air pressure is satisfactory and shift unit does not operate, it should be disassembled and repaired or replaced.

LOCKOUT

Inter-axle differential lockout will operate only when axles are in low range. With lockout engaged, air pressure is present from cab lockout valve through lockout control valve to lockout cylinder. Check for air leaks with lockout engaged. **If vehicle is in a standing position and power divider lockout does not operate, rock or drive vehicle back and forth to make certain the forward axle has completed the shift to low range before attempting to make any repairs.**

SPEEDOMETER ADAPTERS

To locate troubles in adapter operation, trace electrical circuit from ignition switch through circuit breaker, pressure switches to adapters. Also make sure adapter ground connection is satisfactory.

The total (combined) companion flange runout is located in the square where the columns containing the flange bearng cup runout and universal cross shaft runout readings intersect.

CE1944-A

FIG. 9 Companion Flange Combined Runout Chart

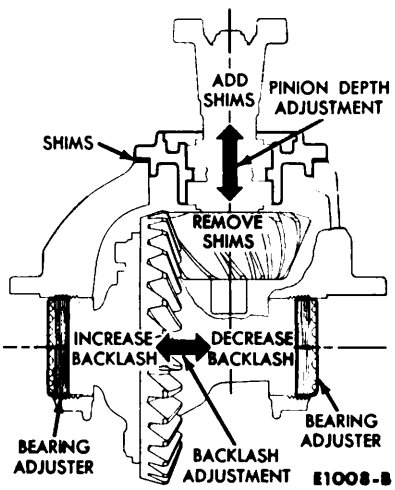

FIG. 10 Pinion and Ring Gear Tooth Contact Adjustment—Except Dana

PINION AND RING GEAR TOOTH CONTACT ADJUSTMENTS (ALL EXCEPT DANA)

Two adjustments affect pinion and ring gear tooth contact. They are pinion depth and backlash (Fig. 10).

The pinion depth adjusting shims are installed between the pinion bearing retainer or cage and the carrier housing; therefore, adding shims would move the pinion out away from the ring gear, and removing shims would move the pinion in toward the ring gear.

The bearing adjusters locate the differential and ring gear assembly in the carrier housing. Tightening the bearing adjuster on the ring gear side of the carrier moves the differential and ring gear into the pinion to decrease backlash. Tightening the bearing adjuster on the pinion side of the carrier moves the ring gear away from the pinion to increase backlash. To move the ring gear away from, or toward, the pinion, loosen one adjuster and tighten the other adjuster the same amount.

SHIM SELECTION

Individual differences in matching the carrier housing and the gear set requires a shim between the pinion bearing retainer sleeve and the carrier housing to locate the pinion for correct tooth contact with the ring gear. In order to adjust the shim pack to the correct thickness for a given gear seat, each pinion gear is marked with an adjustment number (individual variation from nominal dimension) such as the 10 marking (Rockwell) and the 3 marking (Eaton) shown in Fig. 11.

Shim thickness for Ford gears is determined by the gear pattern check. Add or remove shims from the original or nominal shim pack, as required, until a proper gear pattern is established. Adding shims will move the pinion away from the ring gear and removing shims will move the pinion toward the ring gear.

If the original ring gear and pinion are used in reassembly, use the original shim pack removed during disassembly.

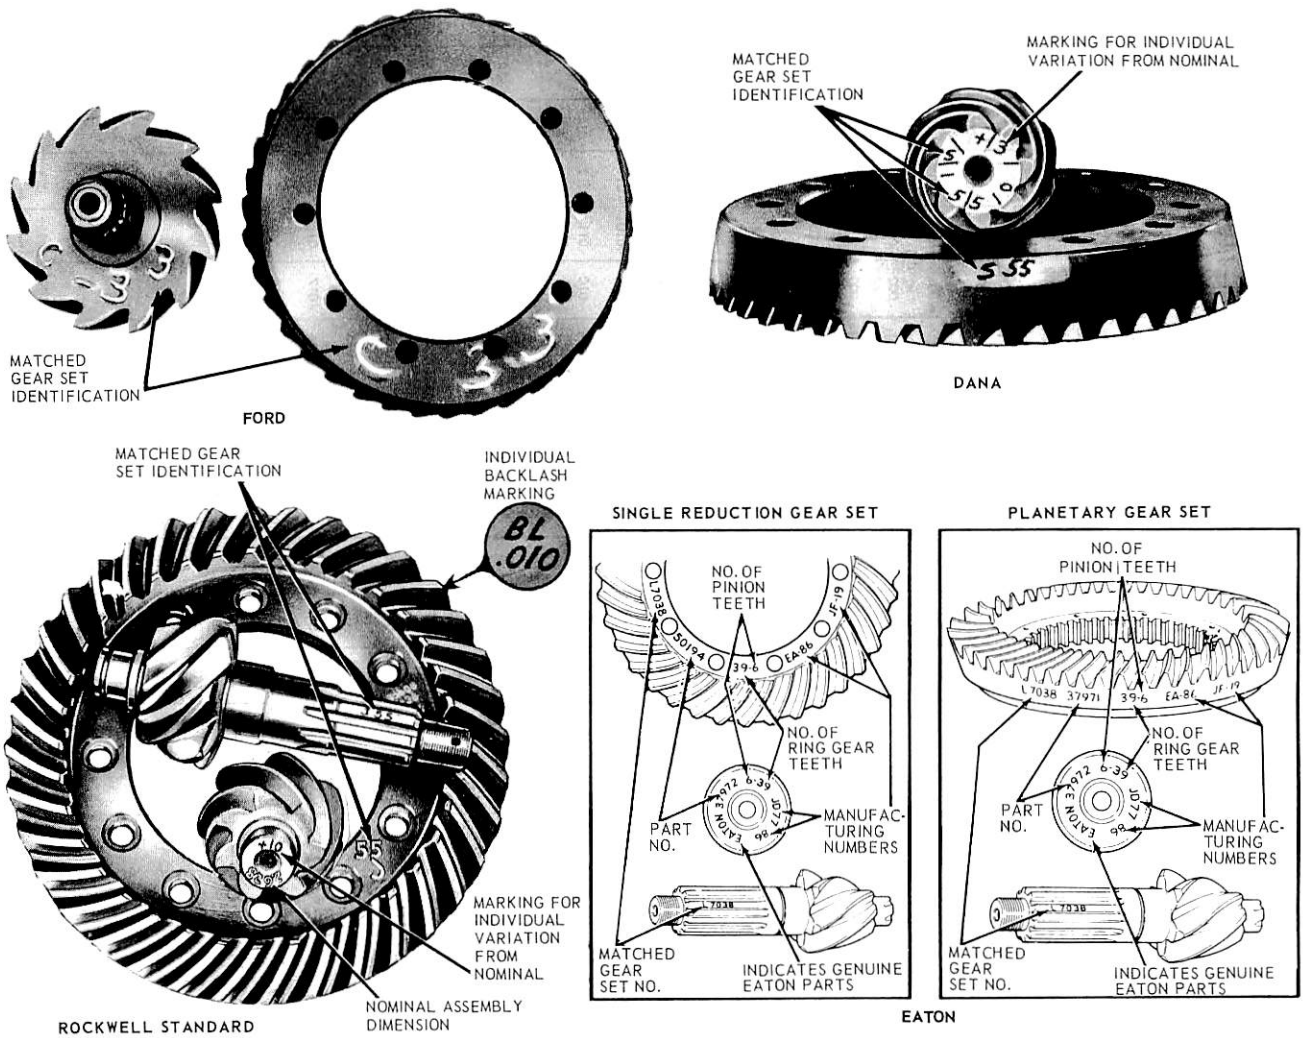
When replacing a ring gear and pinion, it should be noted that the original factory installed shim is of the correct thickness to adjust for individual variations in both the carrier housing dimension and in the original gear set dimensions; therefore, to select the correct shim thickness for the new gear set to be installed, follow these steps:

1. Measure the thickness of the **original shim** with a micrometer.
2. Note the shim adjustment number on both old pinion and new pinion.
3. Refer to Fig. 12 to determine the correct amount of shim thickness change. The amount shown in Fig. 9, under the old pinion shim adjustment number and in line with the new pinion number is the amount of **change that should be made to the original shim thickness if the old pinion is marked 14, for example, and the new pinion is marked -5, the table indicates that 0.019 inch of shim stock should be removed for the original shim pack.**

If the original shim pack was lost or if a new carrier housing is being installed (Eaton axles only), substitute a **nominal** shim for the original, and follow the foregoing procedure for a trial buildup, see Specifications in this manual. If any further shim change is necessary, it will be indicated in the tooth pattern check.

In the case of a Rockwell axle with a lost **original** shim pack or new carrier installation, install a 0.0250.030 inch shim pack for a trial build-up, and run a tooth pattern. The tooth pattern will indicate how much this shim pack should be increased or decreased.

In any Rockwell axle, the shim pack should consist of at least three shims one of which should be thin. Position the thin shim next to the carrier.



E 1766-A

FIG. 11 Typical Pinion and Ring Gear Set Marking

DIFFERENTIAL BEARING PRELOAD AND BACKLASH—ALL EATON AXLES, ROCKWELL STANDARD SINGLE REDUCTION AXLE

1. Mesh the ring gear and pinion with a slight amount of backlash.
2. Set the differential bearing adjusters in the carrier bearing pocket threads, so that they just contact the bearing cups.
3. Carefully position the bearing caps on the carrier. Match the marks made when the caps are removed.
4. Install the hardened flat washers (if so equipped), bearing cap bolts or stud nuts, and alternately tighten them to specified torque. The bolts must be torqued to specifications to be sure that the bearing cups and adjusters are seated. Check the adjusters for freedom of movement as the bolts are tightened. If the adjusters do not turn freely, remove the bearing caps and again inspect for damaged threads or incorrectly positioned caps.
5. On a Rockwell single reduction axle, the adjusters and bearing cups should move easily with the caps tightened to specified torque. On an Eaton axle, loosen the bearing cap bolts or stud nuts until the adjusters and bearing cups can be moved easily.
6. Alternately tighten the bearing adjusters until there is some backlash between the ring gear and pinion and there is some preload on the bearings (Fig. 13). While the bearings are preloaded, rotate the ring gear several turns in each direction to seat the bearing rollers in the cups. **This bearing roller seating is important.**
7. Loosen the bearing adjusters until they are clear of the bearing cups, then tighten them until they just touch the bearing cups.
8. Install a dial indicator on the carrier housing with the button against the back face of the ring gear (Fig. 13).
9. Adjust the differential end play to zero without preloading the differential bearings.
10. From a zero end play and zero preload condition, tighten each bearing adjusting nut one notch to preload the bearings.

CE1986-B

FIG. 12 Drive Pinion Adjusting Shim Thickness Change—Inches (All except Dana)

11. Mount the indicator to check the pinion and ring gear backlash (Fig. 14). Check the backlash at four equally-spaced points on the ring gear.
12. To reduce backlash loosen the pinion side adjuster and tighten the ring gear side adjuster the same number of notches, in order to maintain the preload. To increase backlash, perform the same operation in reverse.

When moving the adjusters, the final movement should always be made in a tightening direction. For example, if one adjuster is to be loosened one notch, loosen it two notches, then tighten it one. This procedure makes certain that the adjuster is contacting the bearing cup, and that the cup will not shift after being put in service.

13. On the Rockwell single reduction axle, the backlash should be set to the same adjustment as before disassembly, if the original gears are being used. If new gears are being installed, adjust to the **BL marking on the ring gear (Fig. 11), and run a tooth pattern check. If the pattern is unsatisfactory at the marked setting, adjust the backlash to the best tooth contact pattern with the limits given in Specifications.**
14. On Eaton axles, adjust the backlash to the best tooth contact pattern within the limits given in Specifications.

PINION BEARING PRELOAD ADJUSTMENT—EATON AND ROCKWELL AXLES

There are two methods of checking pinion preload adjustment.

In one method, the pinionand bearing retainer are completely assembled without the oil seal, and the pinion shaft nut is tightened to specified torque. The preload on the opposed, tapered bearings is then checked by measuring the torque required to rotate the bearings. This can be done by holding the bearing retainer and turning the pinion shaft, or holding the pinion shaft and turning the pinion bearing retainer. The suggested procedure is to clamp the universal joint flange in a vise, and wrap a strong cord around the pinion bearing retainer. Attach a pound pull scale to the cord. Note the pull required to keep the bearing retainer rotating. The pull required to start the retainer moving is disregarded. The reading on the pull-scale multiplied by one-half the diameter (radius) of the bearing retainer at the point the cord is wrapped (in inches) is the in-lb torque.

Pinion bearing preload torque specifications for all axles are given in Specifications.

Pinion bearing preload on these axles is adjusted by installing spacers or various lengths. A shorter spacer increases preload and a longer spacer decreases preload. Usually the original spacer is installed for a trial build-up. Since the original spacer has no identifying mark, it must be measured with a micrometer to determine its length.

The other method of checking pinion bearing preload is to assemble the pinion and bearing retainer, except for the universal joint flange and pinion shaft nut and flat washer. A pinion bearing cone replacer tool is placed over the pinion shaft so that pressure from the press ram can be brought to bear on the tapered roller bearing cones and the bearing spacer. The assembly is then put under a press (Fig. 11). See Specifications at end of this part. While the proper pressure (in tons) is being applied by the press ram, check the torque required to rotate the pinion retainer (Fig. 15). Use a strong cord and pound pull-scale to check the torque.

Note the pull required to keep the bearing retainer rotating. Disregard the pull required to start the retainer moving. The reading on the pull-scale multiplied by one-half the diameter (radius) of the bearing retainer at the point cord is wrapped (in inches) is the in-lb torque.

RING GEAR REPLACEMENT

If a riveted ring gear is to be replaced, center punch the rivet heads on the ring gear end of the rivets. Drill through the rivet heads (Fig. 16) using a drill 1/32 inch smaller than the rivet body. Press out the rivets, then remove the ring gear.

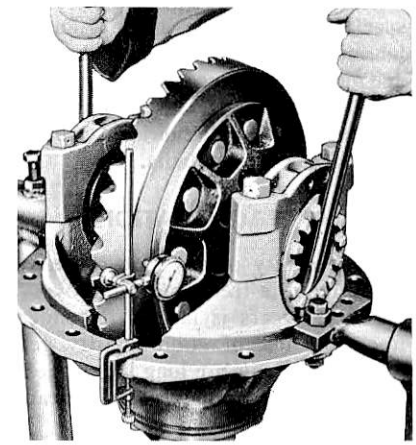
Carefully examine the gear mounting surface and locating flange for high spots, which may have been caused by the old rivet removal. Remove any high spots with a flat hard stone.

Special bolts and nuts should be used instead of rivets to attach the new ring gear to the differential case.

On Eaton axles with riveted ring gears, be sure the bolts used to attach the new ring gear to the differential case are grade 8 bolts. These bolts can be identified by a 6-spoke marking forged on the head of the bolt. Torque to specifications.

Place the new ring gear on the differential case and insert the bolts through the ring gear and into the case.

The bolt heads are installed in the counterbore on the gear tooth side of the



E 1774-A

FIG. 13 Differential End Play and Pre-Load Check

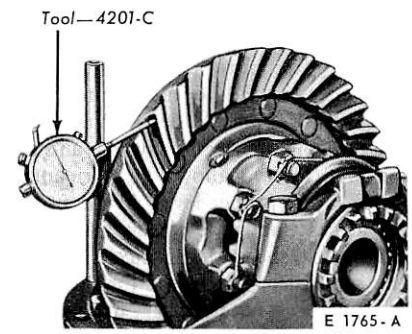


FIG. 14 Backlash Check

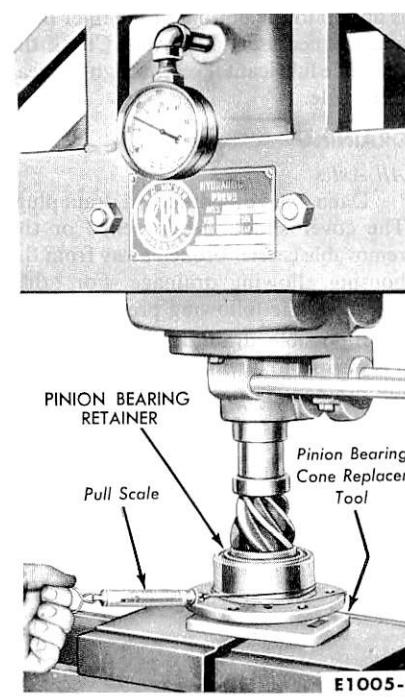

FIG. 15 Pinion Bearing Pre-Load Check

ring gear. The torque limits for these special bolts and nuts, apply to threads lubricated with engine oil. If the bolts and nuts are tightened while dry, add 10 to the limits. If the threads are lubricated with axle lubricant subtract 10 from the torque limits.

REAR AXLE LUBRICATION

The ability of any axle to deliver quiet trouble-free operation over a period of years is largely dependent upon the use of good quality gear lubricants. To insure long life for gears and bearings, use only gear lubricants specified.

Where magnetic drain plugs are used, the plugs should be cleaned or replaced each time the lubricant is changed.

All Axles Except Ford and Tandem

Remove the rear filler hole plug. The lubricant should be level with the bottom of the hole.

Tandem Drive Axles

The axle must be run first, then allowed to stand for 5 minutes. The power divider and the forward rear axle use the same lubrication system and the 5-minute interval allows the lubricant to settle to the proper levels in the power divider case and axle housing. After the 5 minutes, check the lubricant level in the rear filler hole in the forward rear axle only. It is not necessary to check the oil level in the power divider. If the level is up to the bottom of the filler hole of the forward rear axle, the power divider is also adequately lubricated. If the level is not up to the bottom of the filler hole, add the necessary lubricant. Check the rear axle lubricant level through the rear filler hole.

DRAINING

All Axles

Dana axles do not have a drain plug. The cover should be loosened or the removable carrier broken away from the housing allowing drainage. For other axles, use the following procedure:

If possible, drain the lubricant when it is warm and it will run freely, allowing full drainage in minimum time. This is especially desirable in cold weather.

To drain, unscrew the plug at the bottom of the housing and allow sufficient time for all the old oil to run out. On tandem drive axles, it is also necessry to unscrew the plug at the bottom of the power divider for drainage of lubricant in the power divider.

FILLING

Single Reduction Axles—Ford Axle

With the filler hole in the housing cover, fill to the bottom of the filler hole. If the filler hole is in the carrier casting, also fill to the bottom of the filler hole.

To check these axles for proper lubricant level, the filler plug should be backed out slowly. If seepage occurs around the threads of the filler plug, the plug should immediately be turned back in to avoid any drainage. This condition indicates that the specified amount of lubricant is present in the axle.

OTHERS

Fill the axle through the rear filler hole until oil flows from the bottom of the hole. After filling the axle with the specified amount of lubricant, install the oil filler hole plug.

2-Speed and Planetary Double Reduction Axles

Fill the axle through the rear filler hole with the specified amount of lubricant (lubricant should be at the level on the bottom of the filler hole), then install the filler hole plug. If the carrier assembly oil channels are dry, one pint of lubricant should be added through the front filler hole.

Tandem Drive Axles

Fill both axles with the specified amount until the lubricant is level with the bottom of the rear filler hole, and then add the specified amount to the inter-axle differential power divider through the filler hole located in the inter-axle differential power divider case.

Eaton D-Series Tandem drive Axles

Fill the forward drive axle until the oil is level with the bottom of the filler hole in the rear cover. Then, add two pints through the forward filler hole

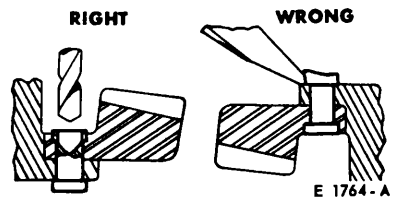

FIG. 16 Removing Ring Gear Rivets

located slightly offset to the right in the top portion of differential carrier. **Do not use the rear hole at the top of the differential carrier as an oil filler hole. Fill the rear axle in accordance with instructions for single reduction, 2-speed or planetary double reduction, depending on the type of axle used.**

REAR WHEEL BEARING AND SEAL REMOVAL AND INSTALLATION

Two types of rear wheel bearing assemblies are used in Ford truck axles. In the semi-floating type axles used in the light series a single outer bearing is used, and is held in place by a retainer. This bearing is attached to the axle shaft and part of the vehicle load is carried on the axle shaft. Refer to Part 11-11 for Removal and Installation details. In the full floating type axle used in the heavier series, double tapered roller bearings are mounted on the axle housing. Vehicle load is carried on the housing and not the shaft. The shaft can therefore be removed without disturbing the bearing.

Wheel bearings of the light Series, semi-floating axles are lubricated at assembly with a special lubricant, and require no further maintenance. A seal is installed behind the bearing to prevent axle lubricant leakage to the bearing. **Replace this seal whenever the hub and drum are removed from the axle. See Part 11-11.**

On all the full-floating axle wheel hubs with tapered roller bearings, a seal is installed behind the inner bearing to keep the wheel bearing lubricant from the brake lining and brake drum. See Part 11-14.

CLEANING AND INSPECTION

INSPECTION BEFORE DISASSEMBLY OF CARRIER

An inspection of the adjustments and parts as the carrier is disassembled can assist in learning the cause of the trouble and in determining what corrections are needed.

Mount the carrier in a holding fixture. Wipe the lubricant from the internal working parts and visually inspect them for damage. Rotate the gears to see if there is any roughness which could indicate worn or damaged bearings or chipped gear. Look carefully at the surface of the gear teeth for any scoring, flaking, or signs of abnormal wear.

Set up a dial indicator (Fig. 11) and check blacklash at several points around the ring gear. Backlash limits for each axle are given in Fig. 12.

If no obvious misadjustment or damage is noted, inspect the gear tooth contact. Coat the gear teeth with the special compound furnished with each service ring gear and pinion (Fig. 17). Too fluid a mixture will run and smear. Too dry a mixture cannot be squeezed out from between the teeth. As shown in Fig. 18, rotate the ring gear back and forth (use a box wrench on the ring gear attaching bolts for a lever), until a clean tooth contact pattern is obtained.

On the larger axles (Fig. 17), it may be desirable to roll a pattern by turning the pinion gear with a wrench on the pinion shaft nut. A sharper pattern will be obtained if a flat steel bar is held lightly against the ring gear to act as a brake.

Certain types of gear tooth contact patterns on the ring gear indicate incorrect adjustment. A noise condition caused by incorrect adjustment can often be corrected by readjusting the gears. Typical patterns and the necessary corrections are shown in Figs. 1 and 2. Gear tooth runout can be detected by an erratic pattern on the teeth. If ring gear runout is suspected, mount a dial indicator to measure the runout of the back face of the ring gear (Fig. 19).

INSPECTION AFTER DISASSEMBLY OF CARRIER

Thoroughly clean all parts. **Synthetic seals must not be soaked or washed in cleaning solvents. Use only clean solvent to wash the bearings. Oil the bearings immediately after cleaning to prevent rusting. A visual inspection of parts will detect any major wear or damage. Clean the inside of the carrier and carrier housing, before rebuilding and assembling the parts. Inspect individual parts as outlined below.**

Gears

Examine the pinion and ring gear teeth for scoring or signs of excessive wear. The pattern taken during disassembly should be helpful in judging if gears can be reused. Worn gears cannot be rebuilt to correct a noisy condition. Gear scoring and flaking are the result of excessive shock loading or the use of an incorrect lubricant. Scored gears cannot be reused.

Examine the teeth and thrust surfaces of the differential gears. Wear on the hub of the differential side gears can cause a chucking noise known as chuckle, when the vehicle is operated at low speeds. Wear of splines, thrust surfaces or thrust washers can contribute to excessive drive line backlash.

Bearing Cups

Check the bearing cups for rings, scores, galling, or erratic wear patterns. The pinion cups must be solidly seated. Check by attempting to insert a 0.0015 inch feeler gauge between the cups and the bottom of their bores.

Cone and roller Assemblies

When operated in the cups, the cone and roller assemblies must turn without any roughness. Examine the roller ends for wear. Step-wear on the roller ends indicates the bearings did not have enough preload, or the rollers were slightly cocked.

Differential Bearing Adjusters

Temporarily install the bearing caps and test the fit of the bearing adjusters in their threads. The adjusters on a Rockwell axle should turn easily when the caps are tightened to specifications.

The faces of the adjusters that contact the bearing cups must be smooth and square. Polish these with a fine abrasive on a flat surface. Replace the adjusters or examine the threads in the carrier if their fit is not proper. **Be sure the bearing caps are on the side they were machined to fit.**

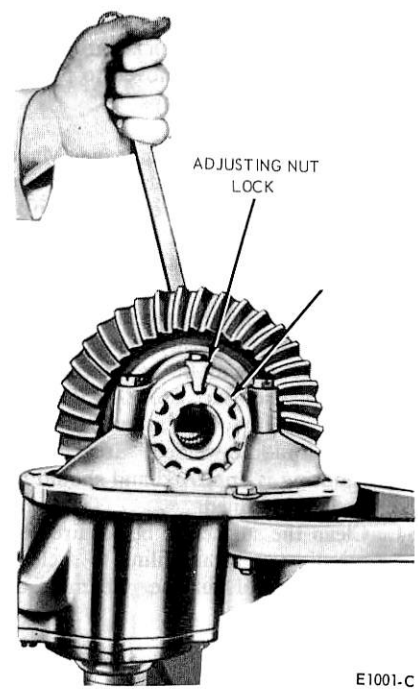

FIG. 18 Gear tooth contact Pattern Check—Ford

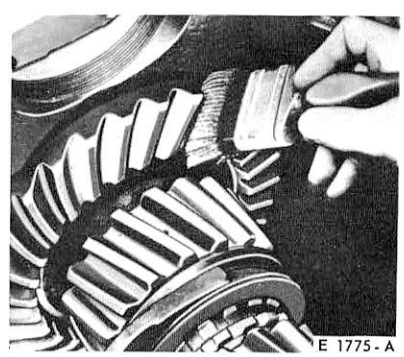

FIG. 17 Rear Wheel Hub—Ford Semi-Floating Axle

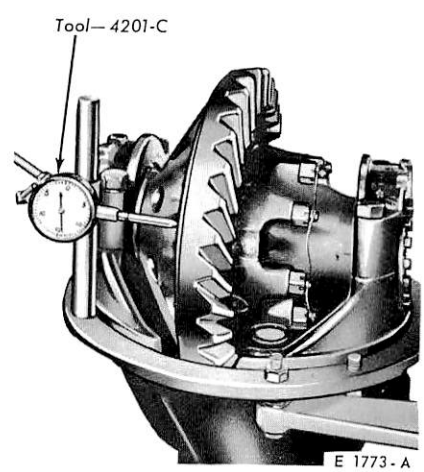

FIG. 19 Ring Gear runout Check—Typical

Universal Joint Flange

Be sure the gears of the flange have not been damaged in removing the drive shaft or in removing the flange from the axle. The end of the flange that contacts the oil slinger or pinion front bearing or flange, must be smooth. Polish this face if necessary. Roughness aggravates backlash noises, and causes wear on the slinger with a resultant loss in pinion bearing preload.

Pinion Retainer

Inspect visually for damage. Be sure the pinion bearing cups are seated. Be sure there are no chips or burrs on the mounting flange. Clean all lubricant passages. If the pinion bearing cups were removed, examine the bores in the retainer carefully. Any nicks or burrs in these bores must be removed to permit proper seating of the cups.

Carrier Housing

Inspect visually for damage. Make sure the differential bearing bores are smooth and the threads are not damaged. Remove any nicks or burrs from the mounting surfaces of the carrier housing.

Axle lubricant leakage in Dana axle housings, due to porosity, sand holes, or small cracks, can be repaired with metallic plastic (part C6AZ-19554-A).

Only repairs to the cast axle housing and the "puddle-welded" area of the axle housing is approved and should be repaired as outlined:

1. Clean the surface to be repaired by grinding or rotary filing to a clean bright metal surface. Chamfer or undercut the hole or porosity to a greater depth than the rest of the cleaned surface. Solid metal must surround the hole. Openings larger than 1/4 inch should not be repaired using metallic plastic.

   Openings in excess of 1/4 inch can be drilled, tapped and plugged using common tools. Clean the repair area thoroughly. Metallic plastic will not stick to a dirty or oily surface.
2. Mix the metallic plastic base and hardener as directed on the container. Stir thoroughly until uniform.
3. Apply the repair mixture with a suitable clean tool, (putty knife, wood spoon, etc.) forcing the epoxy into the hole or porosity.
4. Allow the repair mixture to harden. This can be accomplished by two methods -heat cure with a 250 watt lamp placed 10 inches from the repaired surface, or air dry for 10-12 hours at temperatures above 50 degrees F.
5. Sand or grind the repaired area to blend with the general contour of the surrounding surface.
6. Paint the surface to match the rest of the axle housing.

Further information on the above procedure is available in Group 21, Part-01 in Volume II of the Truck Shop Manual.

Differential Case

Make sure the hubs where the bearings mount are smooth. Check the fit of the differential gears in the counterbores. Examine carefully the thrust surfaces, which are sometimes damaged when the bearings are removed. If the bearing assemblies do not seat firmly on the hubs, failure is certain. Be sure the mating surfaces of the two parts of the case and the face of the ring gear attaching flange are smooth and free from nicks or burrs.

Ring Gear Runout

If the ring gear runout check during disassembly exceeded specifications, the condition may be caused by a warped gear, a distorted or damaged case, or by excessively worn differential bearings.

To determine the cause of the excessive runout, assemble the differential case **without the ring gear,** and make the checks outlined in the following paragraphs.

Press the differential side bearings on the case hubs, and install the case in the differential carrier. Install the bearing caps and torque the cap bolts to specifications. Mount a dial indicator, and then check the runout of the case flange and ring gear pilot. If the runout does not now exceed specifications, install a new ring gear to the case. If the runout at either point is excessive, the gear is probably true and the condition is due to either the case or differential side bearings.

Install new differential side bearings on the case hubs and install the case in the carrier. Check the case runout. If the runout is still excessive, repair or replace the case.

DESCRIPTION

F-250-F-350, E-300, P-350-P-400 AXLES DANA

Four models of Dana rear axles are used in regular production or are available as options on the light trucks.

The regular Model 60 2-pinion full-floating rear axle is used on the F-250 4 x 2 and 4 x 4 trucks, with standard and limited-slip types available. The Model 60 is also used on the P-350, with or without limited-slip differential.

Model 60-3E is used on Econoline E-300.

The Model 70 4-pinion full-floating rear axle is used on the F-350. It is also used on the P-350 and P-400.

This model 70 is of two piece case design and is used for limited slip applications.

Another model 70 axle of 2 pinion design has a one piece case and is used for conventional applications. For this axle, follow model 60 service procedures.

For identification and application of the model 70 axles refer to Fig. 1.

The above axles are of the integral carrier-housing, hypoid gear type, in which the centerline of the drive pinion is mounted below the centerline of the ring gear (Fig. 2).

2-Pinion Design	4-Pinion Design	Ratio	Usage

D2TA-HDA	D0TA-BT	4.88	P350/P400

CE2395-A

FIG. 1 Axle Identification and Application

The integral pinion gear and shaft is supported by two opposed tapered roller bearings which are assembled in the forward side of the carrier housing. Pinion locating shims, installed between the rear bearing cup and the cup seat, control the drive pinion depth adjustment. The pinion bearing preload is controlled by shims located between the pinion front bearing and the shoulder on the drive pinion shaft.

The differential case assembly is supported by two opposed tapered roller (side) bearings and cups, which are retained in the housing by removable caps. Shims, installed between each differential side bearing and the shoulder on the case, perform three functions: they take up the differential case side clearance; they adjust the backlash between ring gear and pinion; and they establish differential side bearing preload.

A cover on the rear of the carrier housing provides access for inspection, removal and installation of the differential assembly and drive pinion. A metal tag, stamped with the gear ratio plus the number of teeth on the ring gear and pinion, is secured to the housing by one of the cover bolts.

Vehicles equipped with limited-slip differential assemblies will have the letters L-S stamped on the metal tag.

Models 60, 60-3E and 70 (Fig. 2) have full-floating axle shafts, meaning that loads are borne by the axle housing and the shafts can be removed without disturbing the wheel bearings, which are double tapered roller bearings.

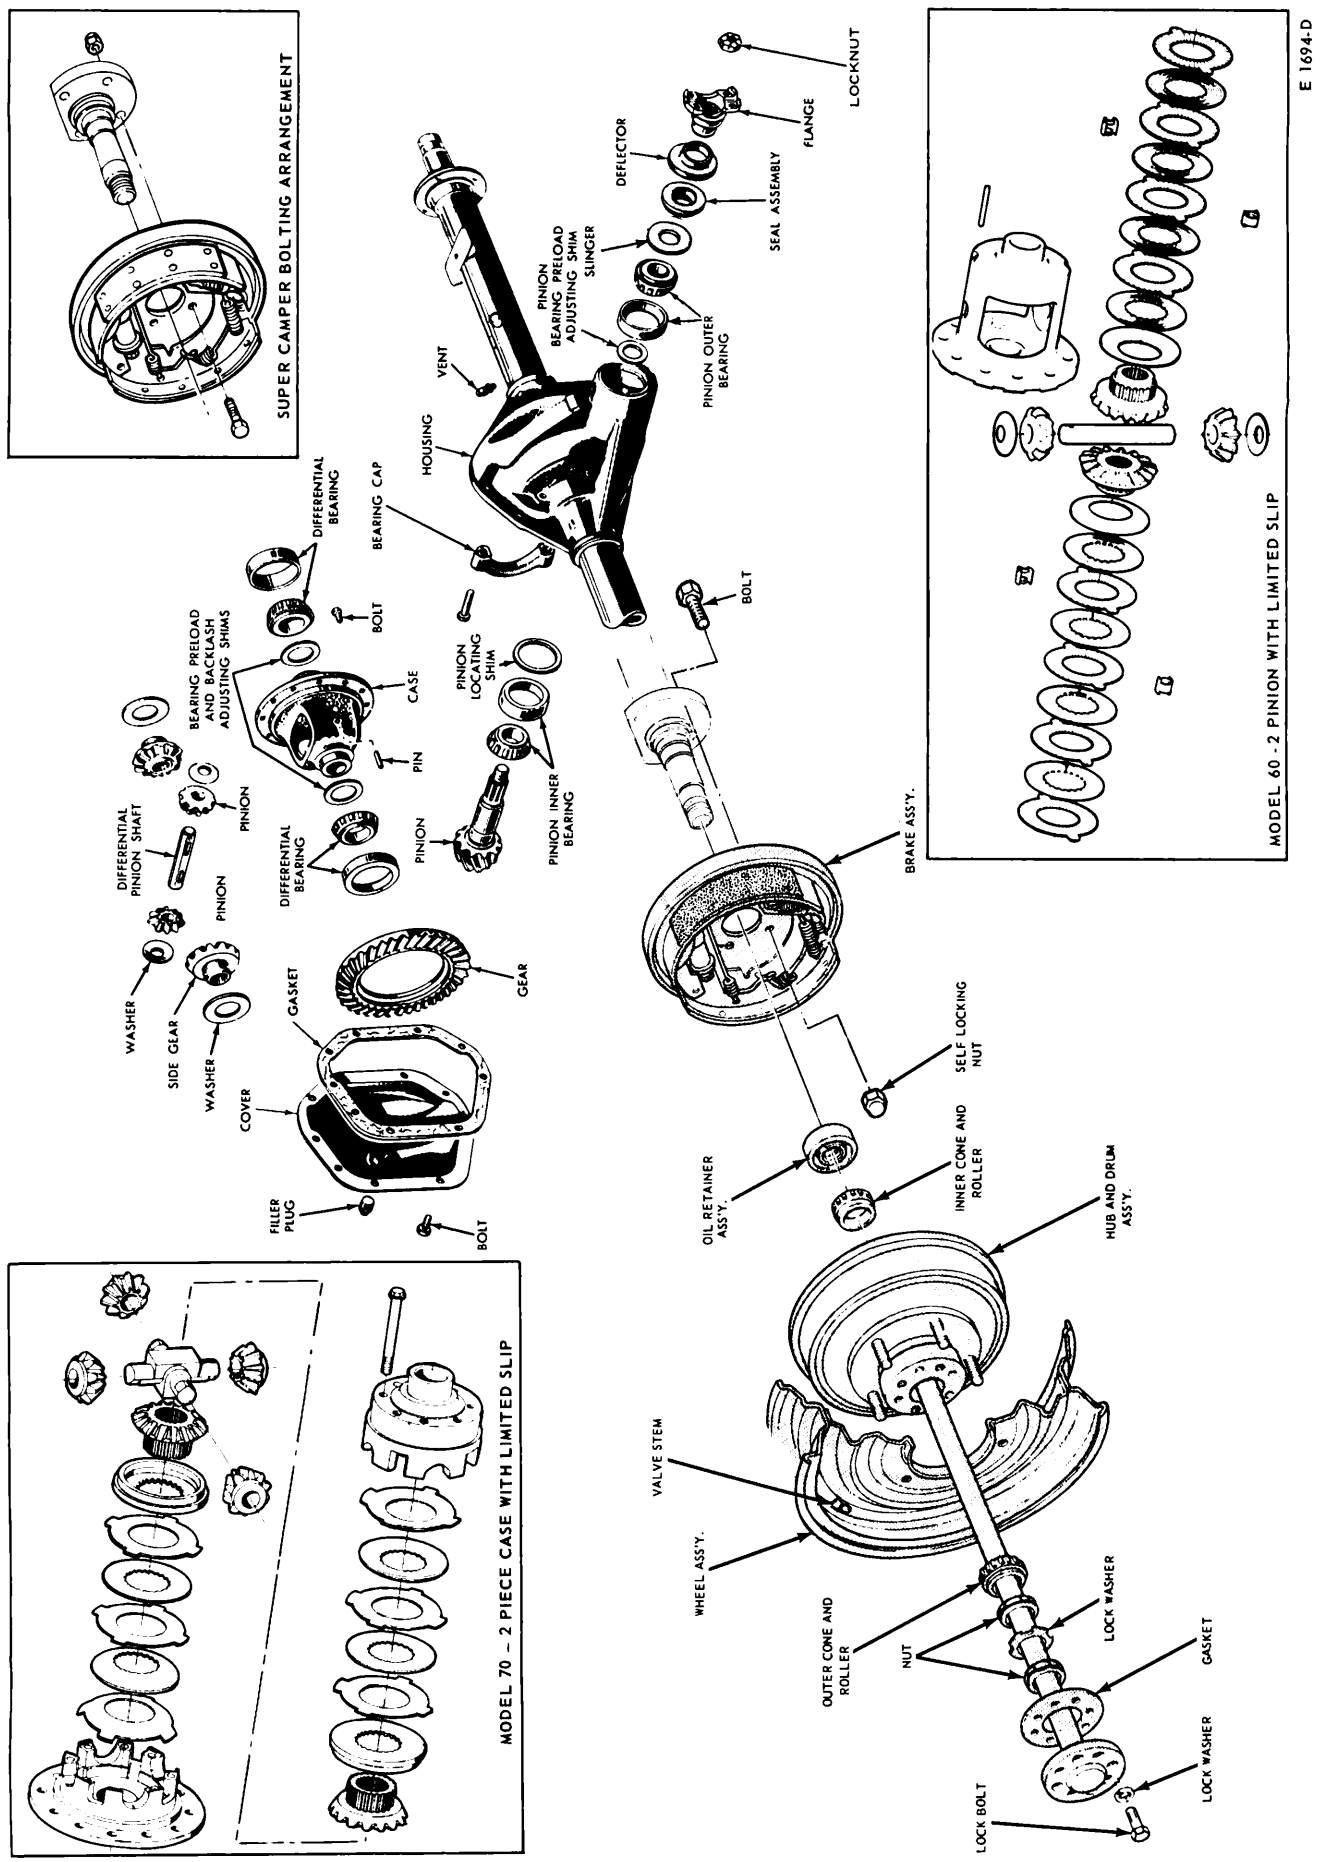

FIG. 2 Typical Model 60 and 70 Locking/Non-Locking Rear Axle—Dana

ADJUSTMENTS

Axle shafts, wheel hubs, wheel hub bearings, and the wheel hub grease seals can be replaced without removing the differential assembly from the axle housing or the rear axle assembly from the vehicle.

The axle shafts, wheel hub, bearing and grease seals may be replaced, lubricated, or adjusted as outlined in Part 11-14.

REMOVAL AND INSTALLATION

REAR AXLE

Removal

1. Loosen the wheel stud nuts and the axle shaft retaining bolts.
2. Disconnect the rear shock absorbers from the rear axle, and unclamp the rear stabilizer bar. Then raise the rear end of the vehicle frame until the weight is off the rear springs. Place safety stands under the frame in this position.
3. Disconnect the flexible hydraulic line at the frame and disconnect the axle vent hose at the axle connection.
4. Disconnect the parking brake cable (if so equipped) at the equalizer, and remove the cables from the cable support brackets.
5. Disconnect the drive shaft from the rear U-joint flange.
6. Remove the nuts from the spring clips (U-bolts), and remove the spring seat caps.
7. Roll the axle from under the vehicle, and drain the lubricant. Remove the wheels. Mount the axle in a work stand. To remove axle shafts, hubs and drums refer to Group 11, Part 14.

Installation

1. Apply a coating of ESA-M1C75-B lubricant to the lip surface; then, replace the hub inner grease seal. Refer to Group 11, Part 14 for hub and bearing installation; (use new axle shaft gaskets) then, install the axle shafts through the housing ends so that they will spline to the differential side gears. Install the shaft retaining bolts and lockwashers.
2. After installing rear wheels, roll the axle assembly under the vehicle.
3. Install the spring clips (U-bolts) and spring seat caps. Torque the nuts to 165-185 ft-lbs.
4. Connect the rear shock absorbers, and clamp the stabilizer bar in position.
5. Lower the vehicle to the floor. Connect the drive shaft to the rear universal joint flange.
6. Connect and adjust the parking brake cables (if so equipped).
7. Connect the hydraulic brake hose and bleed the brakes. Also connect the axle vent hose to the axle fitting.
8. Fill the axle with the proper grade and amount of lubricant.

DISASSEMBLY AND ASSEMBLY

PINION, DRIVE GEAR AND DIFFERENTIAL REPAIR

Except for the overhaul procedures on the differential case itself, the overhaul procedures given here apply to both the conventional, locking and limited-slip differential axles. Overhaul procedures for the limited-slip differential case assembly are given in Part 15-42.

Disassembly

1. Remove the rear axle from the vehicle as outlined in Removal and Installation.
2. Clean around the differential housing cover, and remove it. Discard the cover gasket. Remove the differential bearing caps.
3. Install the housing spreader Tool 4000-D, or Tool 4000-C (Fig. 3), making sure the tool hold-down clamp screws are tight if Tool 4000-C is used. Spread the housing until the differential assembly can be forced out with a small pry bar. **Do not spread the housing more than 0.020 inch to remove the differential assembly. Loosen the spreader thread immediately after lifting out the differential assembly to prevent springing the housing.**
4. If the differential bearings are to be removed use T53T-4221-C.

A shim pack will be found behind each differential bearing cone. These shim packs control differential bearing preload and pinion and ring gear backlash. When the differential bearing cones are removed, these shim packs are usually damaged by the puller jaws and should be replaced with new shims. Measure each shim pack, shim by shim, and write down the total thickness and location of each pack.

If the axle is equipped with a

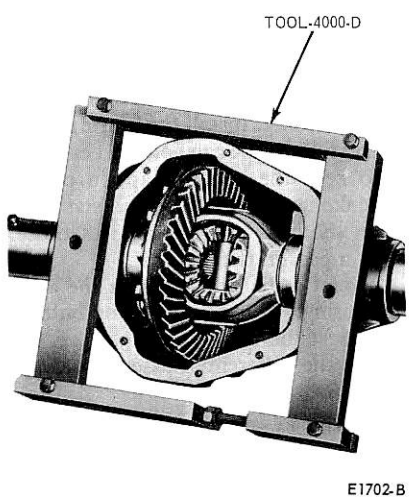

FIG. 3 Spreading Axle Housing

limited-slip differential, see part 15-42 for service procedures.

5. Remove the ring gear from the differential case. With a punch, drive out the differential pinion shaft locking pin. remove the differential pinion shaft (Fig. 4), differential pinions, and thrust washers. Remove the side gears and thrust washers. Rotate the side gears to permit the pinion gears to turn to the opening of the case.
6. If the pinion rear bearing cone is to be replaced, use the type of tool shown in Fig. 5.
7. Attach a slide hammer puller tool to the pinion outer bearing cone and remove the bearing cone, slinger, and oil seal from the housing.
8. Clean and inspect the axle parts as given in Part 15-01.

ASSEMBLY OF CONVENTIONAL DIFFERENTIAL

1. Lubricate; then install the side gears and thrust washers, pinions and thrust washers,and the pinion shaft in the differential case. To do this easily; assembly the side gears and thrust washers, hold them in place, then position the pinion gears to hold the side gears in place. Install the differential shaft locking pin. Peen metal of the case over the pin to lock it in place.
2. Install the ring gear on the differential case, and torque the attaching bolts to specification.

DIFFERENTIAL BEARING END PLAY MEASUREMENT

1. Press the differential bearings onto the case without shims (Fig. 6). The bearing must bottom on the case shoulder.
2. Place the cups on the differential bearings and install the assembly in the housing. Install the bearing caps and tighten the cap bolts just enough to keep the bearing caps in place. Make sure that the letters stamped on the caps are the same as those stamped on the carrier.
3. Mount a dial indicator on the axle housing, with the indicator button against the ring gear (Fig. 7).
4. Pry the differential assembly away from the dial indicator, using a screwdriver between the bearing cup and the case, and set the indicator at zero. Pry the differential assembly toward the indicator (Fig. 8) and note the indicator reading. This reading indicates the amount of shims needed behind the differential side bearings to take up the total clearance between the differential bearing cups and the case. Record this reading.
5. Remove the bearing caps and lift the differential assembly from the housing. **Do not install shims under the differential bearings at this time. The total-clearance reading obtained in the above step must be integrated with a second reading to be obtained after the pinion has been installed and pinion depth has been adjusted. The two readings are used to calculate the shim thickness necessary to obtain proper differential bearing pre-load and ring gear backlash, as well as end play adjustment.**

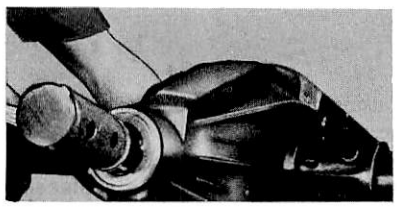

FIG. 4 Removing Pinion Shaft

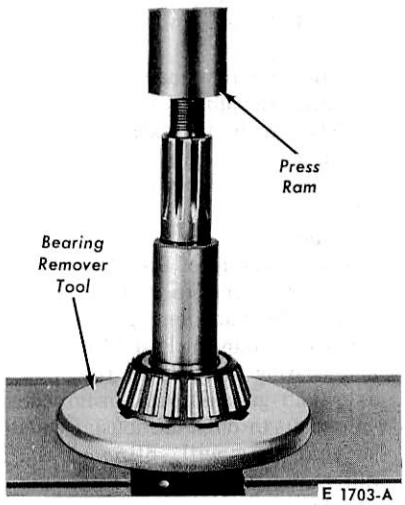

FIG. 5 Removing Pinion Bearing Cone

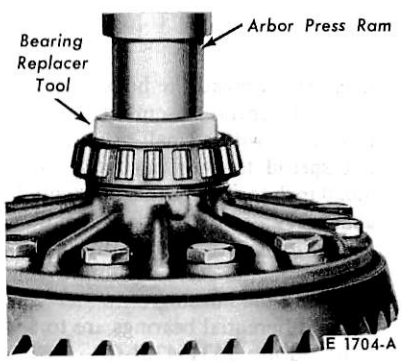

FIG. 6 Installing Differential Bearing

DRIVE PINION INSTALLATION AND DEPTH ADJUSTMENT

If the pinion bearing cups were removed, install them as shown in Fig. 9.

As in all other axles, two separate adjustments affect pinion and ring gear tooth contact. They are pinion depth (location) and backlash. On all other truck axles, the locating shim pack is installed between the pinion retainer and the carrier. On Dana axles, the pinion locating shim pack is installed between the pinion rear bearing cup, and the carrier housing (Fig. 10). Therefore, **adding** shims moves the pinion **toward** the ring gear; removing shims moves the pinion away from the ring gear.

Estimated Shim Pack

If the original gear set is being installed, install the pinion with the original shim pack and check the pinion location with a depth gauge.

If the ring gear and pinion is being replaced, note that the original factory installed (pinion locating) shim is of the correct thickness to adjust for individual variations in both the carrier housing dimension and in the original gear set

dimension. Therefore, to estimate the correct shim thickness for the new gear set to be installed, follow these steps:

1. Measure the thickness of the **original pinion locating shim** with a micrometer.
2. Note the shim adjustment number on both the old pinion and the new pinion. Each pinion gear is marked with an adjustment number such as the marking in Fig. 11, Part 15-01.

Refer to specifications for the correct amount of shim thickness change. The amount that is shown under the new pinion shim adjustment number and in line with the old pinion number is the amount of change that should be made to the **original** shim pack was made to the **original** shim thickness.

If the old pinion is marked 4, for example, and the new pinion is marked -2, the table indicates that 0.006 inch of shim stock should be added to the **original** shim pack.

If the **original** shim pack was not lost or if a new axle housing is being installed, substitute a **nominal** 0.030 inch shim for the **original,** and repeat the foregoing steps for a trial build-up.

If any further shim change is necessary, it will be indicated in the depth gauge check.

A new ring gear and pinion should always be installed in an axle as a matched set (never separately). **Be sure that the same matching number appears on both the drive pinion and the ring gear.** Note the number S55 in Fig. 11, Part 15-01.

Install the pinion with the estimated shim pack, and check the pinion location with a depth gauge as outlined in the following procedure.

Depth Gauge Check

1. Install the pinion locating shim pack and pinion bearing cups. Refer to Specifications for proper tool application.
2. Press the rear bearing onto the pinion shaft.
3. Position the pinion and rear bearing assembly by inserting it from the inner side of the axle housing. Position the front bearing cone (without preload shim pack) and the universal joint flange on the pinion shaft. Press all these parts into place under a press or with a flange replacer tool.
4. Install the pinion shaft flat washer and nut, and torque the nut until pinion bearing preload is between 20-40 in-lbs. As the nut is torqued, rotate the pinion shaft in both directions to seat the bearing rollers. If required, add or subtract shims to obtain 20-40 in-lbs. Torque the nut to specifications.

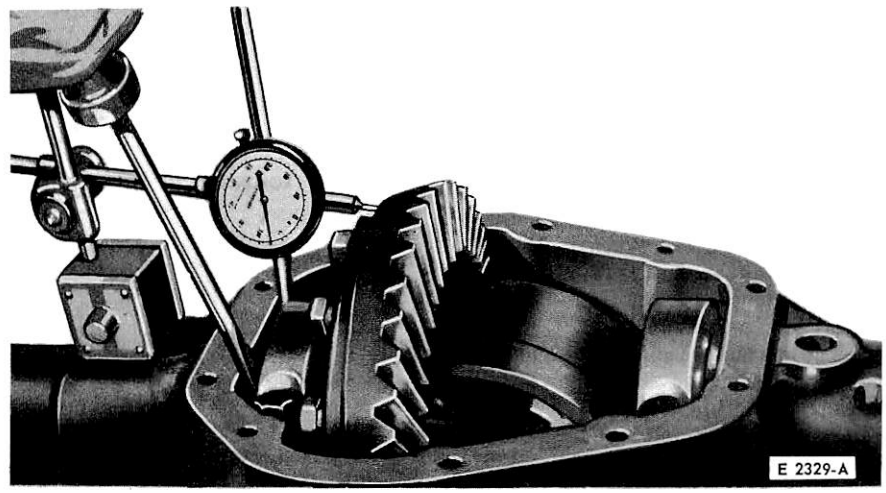

FIG. 7 Checking Differential End Play—First Step

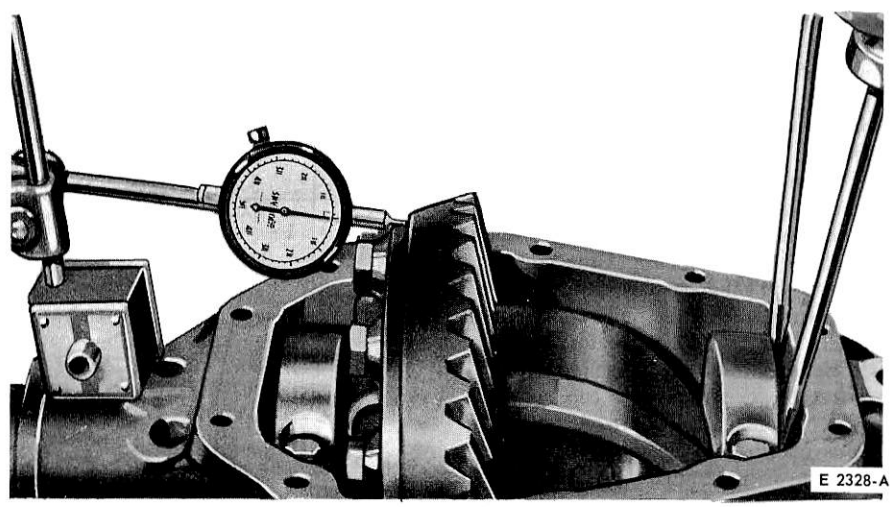

FIG. 8 Checking Differential End Play—Final Step

5. Check the pinion bearing preload (Fig. 11). Disregard the torque required to start the pinion rotating. The specified torque of 10 to 30 in-lbs refers to the torque required to keep the pinion rotating after it has been started.

After the pinion is installed in the housing and the bearing preload is within limits, check the depth setting (actual assembly dimension) with the gauge shown in Fig. 12.

Place the gauge shaft and discs in the differential bearing pockets and securely tighten the bearing caps.

6. Attach the dial indicator to its holder and place it on the higher step of the gauge block. Place the gauge block squarely on the pinion gear and squarely against the gauge shaft.

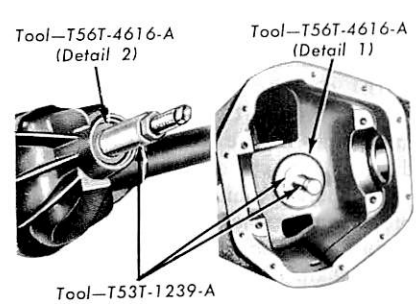

FIG. 9 Installing Pinion Bearing Cup—Models 60 and 70

7. With the indicator button resting on the proper step of the gauge block, set the dial face to read zero. Swing the indicator (Fig. 12) to the highest point on the gauge shaft and note the reading at the highest point. **The highest point on the gauge shaft is the point of highest indicator reading while the indicator hand is moving clockwise. When the hand reverses and starts moving counterclockwise, the highest point has been passed.**

The indicator reading at the highest point on the gauge shaft shows the actual assembly dimension with reference to the nominal assembly dimension. The nominal assembly 3.125 inches for Models 60 and 60-3E, and 3.500 inches for Model 70 axle. The nominal dimension is the distance from the ground surface on the pinion gear rear face to the centerline of the ring gear. The highest point on the installed gauge shaft is exactly 1/2 inch higher than the ring gear centerline. The installed gauge block step heights are exactly 1/2 inch greater than the nominal assembly dimensions for each axle.

When the gauge block is resting on a zero-marked pinion installed exactly at the nominal assembly dimension, the top of the gauge block and the highest point on the gauge shaft are exactly the same distance from the pinion gear rear face. In this case, the indicator, having been set at zero on the gauge block, will read zero when moved to the highest point on the gauge shaft. A plus or minus reading on the indicator at the highest point on the gauge shaft indicates, therefore, that the actual assembly dimension is not the same as the nominal assembly dimension. The plus and minus indicator readings are translated directly into plus and minus variations from the nominal assembly dimension.

The indicator reading at the highest point on the gauge shaft must correspond with the pinion gear marking, if the actual assembly dimension is correct. For example, a pinion marked minus 3 is installed at the proper depth when the indicator reads minus 3 at the highest point on the gauge shaft. Likewise, a pinion marked plus 3 is installed at the proper depth when the indicator reads plus 3 at the highest point on the gauge shaft.

A plus reading (clockwise from zero) at the highest point on the gauge shaft with a zero-marked pinion, means that the actual assembly dimension is too great in the amount of the plus reading. To correct, add shims in thousandths of an inch that correspond to the plus reading. For example, an indicator reading of plus 10 with a zero-marked pinion means that 0.010 inch in shims must be added to the rear bearing cup pack. The **addition** of shims will move the pinion gear closer to the ring gear and **decrease** the actual assembly dimension (Fig. 10).

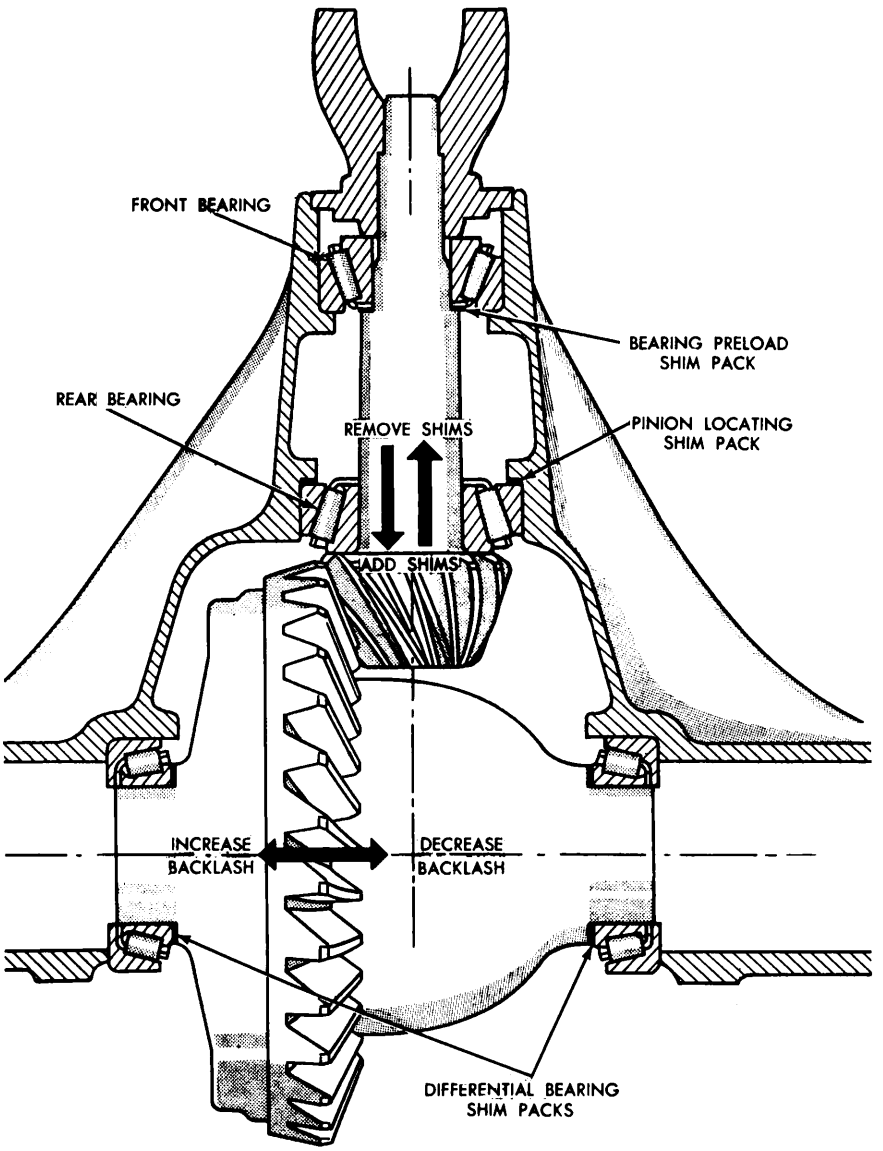

FIG. 10 Pinion and Ring Gear Tooth contact Adjustments

Likewise, a minus reading (counterclockwise from zero) at the highest point on the gauge shaft with a zero-marked pinion, means that the actual assembly dimension is deficient in the amount of the minus reading. To correct, remove shims in thousandths on an inch equal to the minus reading. This will increase the actual assembly dimension.

Whenever the pinion rear bearing cup shim pack is changed, install the pinion and recheck the pinion depth.

8. After the pinion depth has been adjusted and checked, remove the universal joint flange and front bearing. Add or subtract from the original front pinion bearing preload shim pack, the same amount in thousandths of an inch that was added or subtracted from the shim pack behind the rear bearing cup (Fig. 10). Install the bearing preload shim pack, the outer bearing, the universal joint flange, washer and nut. Torque the flange nut to 250-270 ft-lbs on all models.
9. Check the pinion bearing preload (Fig. 11). The preload should be 20-40 in-lbs. Add shims to decrease preload and remove shims to increase preload.

If the original bearing preload shim pack has been lost, or there is reason to believe that it was not correct, install a 0.065 inch shim pack for a trial build-up. Check the pinion bearing preload and adjust as necessary to obtain 20-40 in-lbs preload.

10. When the pinion bearing preload is correct, remove the universal joint flange. Install the oil slinger on the outer side of the front pinion bearing and install the grease seal. Refer to Specifications for the proper seal installer tool.

DIFFERENTIAL BEARING PRELOAD AND RING GEAR BACKLASH ADJUSTMENT

1. Refer to the reading taken in step 4 under Differential Bearing End Play Measurement. This reading (taken before the pinion was installed) represents the total clearance between the differential side bearing cups and the case.
2. Again install the differential assembly in the housing (this time with the pinion installed), and tighten the bearing caps lightly. Install the dial indicator with the button against the back face of the ring gear. Move the differential and ring gear assembly tight against the pinion gear, and then set the dial indicator to zero. Move the differential and drive gear assembly toward the indicator, and note the reading.
3. This reading indicates the amount of shims necessary to take up the clearance between the bearing cup and the case at the **ring gear side of** the differential assembly. Subtract this reading from the previously recorded total reading to obtain the amount of shims necessary to take up the clearance between the bearing cup and the case at the **pinion side** of the differential. Increase this pinion-side shim pack by an additional 0.015 to 0.020 inch in order to provide correct bearing preload and backlash. EXAMPLE (Fig. 13): Total clearance previously recorded....0.070 inch Less reading in foregoing step 2 (Amount of shims necessary to take up clearance at ring gear side)....0.038 inch Shims necessary to tatake up clearance at pinion side-0.032 inch Plus 0.015 inch shims for preload and backlash....0.015 inch Total amount of shims at pinion side....0.047 inch.
4. Remove the bearing caps, and lift the differential assembly from the housing. Remove the differential side bearings, and install the proper amount of shims on each side of the differential case. Press the side bearings onto the case until they are firmly seated against the shims.
5. Install the housing spreader, spread the housing not more than 0.020 inch, and install the differential assembly. Install the bearing caps, and remove the spreader. Install and torque the cap bolts to specification.
6. Install a dial indicator to check the backlash at four equally spaced points around the ring gear. The backlash must be held to 0.004-0.009 inch and cannot vary more than 0.002 inch between positions checked. If the backlash does not fall within these specifications, change the shim packs behind both differential side bearings, as required.
7. Check gear tooth contact pattern as given in Part 15-01.
8. Position a new gasket on the rear face of the axle housing, and install the rear cover and ratio identification tag. Torque the cap screws to 30-40 ft-lbs.
9. Place new gaskets on the axle shafts, and install the axle shafts. Install the retaining bolts and lockwashers. Torque the bolts to 60-70 ft-lbs.
10. Install he rear axle on the vehicle as outlined in Adjustments under Rear Axle Installation.

DESCRIPTION AND OPERATION

DESCRIPTION

The Ford conventional rear axle (Fig. 1 and Fig. 2) is used on the F-100, Bronco and Econoline (E-100 and E-200) Series. If a limited-slip differential is desired on a F-100 truck, a Traction-Lok (See Part 15-05) differential is available as optional equipment.

The rear axle is of the banjo housing, hypoid gear type, in which the centerline of the pinion is mounted below the centerline of the ring gear (Fig. 1).

The pinion gear and the pinion bearings are assembled in a pinion retainer which is bolted to the carrier. The pinion is straddle mounted; that is, it is supported by bearings both in front of and to the rear of the pinion gear. Two opposed tapered roller bearings support the pinion shaft in front of the pinion gear A straight roller (pilot) bearing supports the pinion shaft at the rear of the pinion gear. Pinion and ring gear tooth contact is adjusted by adding or removing shims from between the pinion retainer and the carrier housing.

The differential assembly is mounted on two opposed tapered roller bearings, which are retained in the carrier by removable caps. The entire carrier assembly is bolted to the axle housing.

Ball bearing assemblies (rear wheel bearings) are pressed onto the outer ends of the axle shafts and set in the outer ends of the axle housing. These bearings support the semi-floating axle shafts at the outer ends. The inner ends of the shafts spline to the differential side gears. Bearing retainer plates hold the shafts in the housing. The left and right axle shafts are not interchangeable, the left shaft being shorter than the right.

A metal tag stamped with the model designation and gear ratio is secured to all Ford-produced axles under one of the carrier-to-housing bolts (Fig. 3). It is important to use the model designation for obtaining the correct replacement parts.

REAR AXLE SHAFT, WHEEL BEARING AND OIL SEAL REMOVAL AND INSTALLATION

The rear axle shafts, wheel bearings, and oil seal can be replaced without removing the differential assembly from the axle housing.

Synthetic wheel bearing seals are used. Removal and insertion of rear axle shafts must be performed with caution. The entire length of the shaft (including spline) up to the seal journal must pass through the seal without cutting of the seal element during axle removal or installation will result in early seal failure. **Synthetic seals must not be cleaned, soaked, or washed in cleaning**

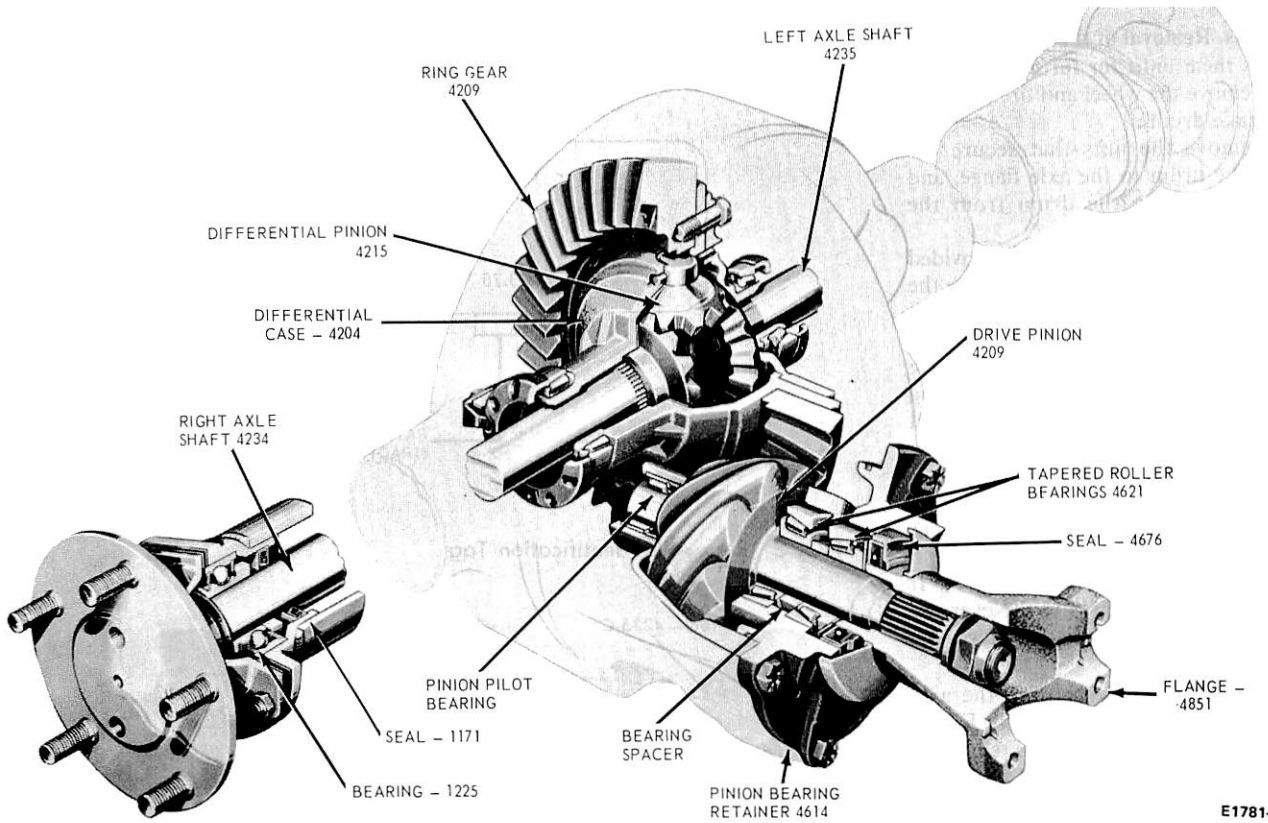

FIG. 1 Rear Axle—Ford

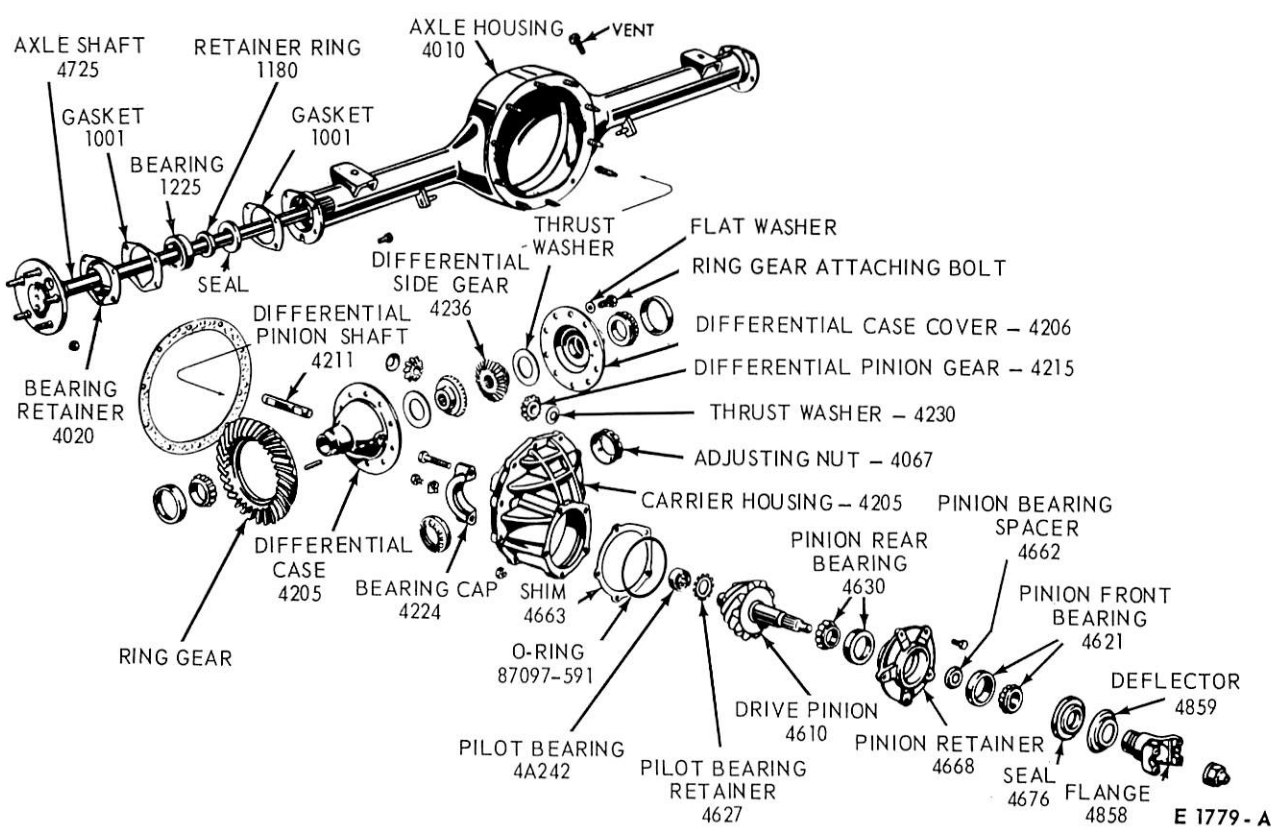

FIG. 2 Rear Axle—Ford—Disassembled

solvents. Removal of the wheel bearings makes them unfit for further use.

1. Remove the wheel and tire from the brake drum.
2. Remove the nuts that secure the brake drum to the axle flange, and then remove the drum from the flange.
3. Working through the hole provided in each axle shaft flange, remove the nuts that secure the wheel bearing retainer plate. Then pull the axle shaft assembly out of the axle housing (Fig. 4). **The brake backing plate must not be dislodged. Install one nut to hold the plate in place after the axle shaft is removed.**
4. If the rear wheel bearing is to be replaced, loosen the inner retainer ring by nicking it deeply with a cold chisel in several places (Fig. 5). It will then slide off easily. Never use heat to do this. To do so will weaken the parts.
5. Remove the bearing from the axle shaft with the tool shown in Fig. 7.
6. **Whenever a rear axle shaft is replaced, the oil seal must be replaced. Remove the seal with Tool 1175-AB and a slide hammer (Fig. 6).**
7. Inspect the machined surface of the axle shaft and the axle housing for rough spots or other irregularities which would affect the sealing action of the oil seal. Check the axle shaft splines for burrs, wear or damage. Carefully remove any burrs or rough spots. Replace worn or damaged parts.
8. Lightly coat wheel bearing bores with axle lubricant.
9. Place the retainer plate on the axle shaft, and press the new wheel bearing on the shaft with the tool shown in Fig. 7. **Do not attempt to press on both the bearing and the inner retainer ring at the same time.**
10. Using the bearing installation tool (Tool 1225-DA) press the bearing inner retainer ring on the shaft until the retainer seats firmly against the bearing. Never use heat to do this. To do so will weaken the parts.
11. Install the new oil seal with tools shown in Fig. 8. Wipe a small amount of oil-resistant sealer on the outer edge of the seal before it is installed. **Do not put sealer on the sealing lip.**
12. Place a new gasket between the housing flange and the backing plate, and then carefully slide the axle shaft into the housing so that the rough forging of the shaft will not damage the oil seal. Start the axle splines into the side gear, and push the shaft in until the bearing bottoms in the housing.
13. Install the bearing retainer plate and the nuts that secure it. Torque the nuts to specifications.
14. Install the brake drum and the drum attaching (tinnerman) nuts.
15. Install the wheel and tire on the drum.

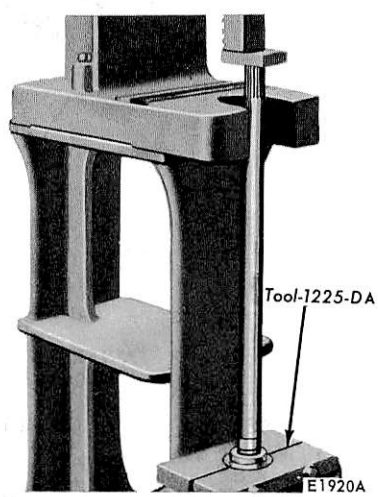

FIG. 7 Removing Rear Wheel Bearing

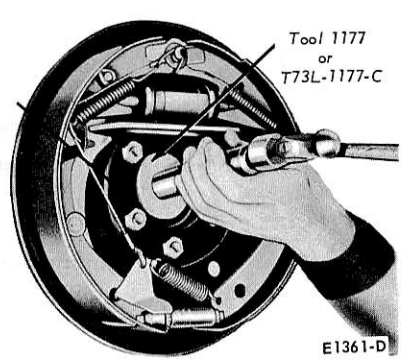

FIG. 8 Installing Rear Wheel Bearing Oil Seal

DRIVE PINION OIL SEAL REMOVAL AND INSTALLATION

COLLAPSIBLE SPACER

Synthetic seals must not be cleaned, soaked or washed in cleaning solvent.

The drive pinion oil seal can be replaced without removing the differential carrier assembly from the axle housing.

1. Raise the vehicle and install safety stands. Remove both rear wheels and brake drums.
2. Make scribe marks on the drive shaft end yoke and the axle U-joint flange to insure proper position of the drive shaft at assembly (Fig. 9). Disconnect the drive shaft from the axle U-joint flange. **Be careful to avoid dropping the loose universal joint bearing cup.** Hold the cups on the spider with tape. Mark the cups so that they will be in their original position in relation to the flange when they are assembled. Remove the drive shaft from the transmission extension housing. Install an oil seal replace tool in the transmission extension housing to prevent transmission fluid leakage. Refer to the transmission Group for the appropriate tool.
3. Install an in-lb torque wrench on the pinion nut. Record the torque required to maintain rotation of the pinion shaft through several revolutions.
4. Scribe the pinion shaft and the U-joint flange inner surface for assembly realignment. While holding the flange with the tool shown in Fig. 10 remove the integral pinion nut and washer.

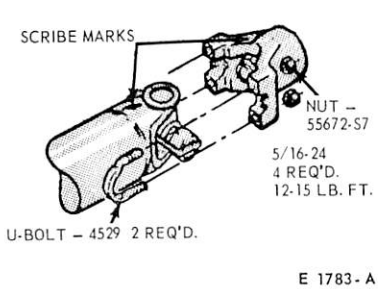

FIG. 9 Drive Shaft-to-U-Joint Connections

5. Clean the pinion bearing retainer around the oil seal. Place a drain pan under the seal, or raise the front of the vehicle higher than the rear.
6. Using the tool shown in Fig. 11, remove the U-joint flange.
7. Using the tool shown in Fig. 12, remove the drive pinion oil seal.
8. Clean the oil seal seat.
9. Coat the outer edge of the new seal with a small amount of oil resistant sealer. **Do not put any of the sealer on the sealing lip.** Install the seal in the retainer, using the applicable tool shown in Fig. 13.
10. Check splines on the pinion shaft to be sure they are free of burrs. If burrs are evident, remove them by using a fine crocus cloth, working in a rotational motion, then wipe clean. Apply a small amount of lubricant to U-joint splines.
11. Install the U-joint flange using the tool shown in Fig. 14.
12. Install a new integral nut and washer on the pinion shaft. (Apply a small amount of lubricant on the washer side of the nut).
13. Hold the flange with the tool shown in Fig. 10 while the nut is being tightened.
14. Tighten the pinion shaft nut, rotating the pinion occasionally to insure proper bearing seating, and take frequent preload readings until the preload is at the original recorded reading established in Step 3.

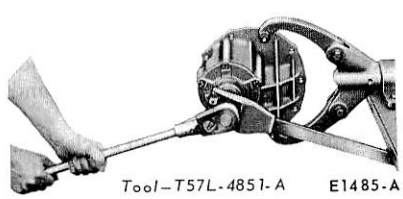

FIG. 10 Removing Pinion Shaft Nut

15. After original preload has been reached, tighten the pinion nut slowly, until an additional preload of 8 to 14 in-lb over the original reading is reached. (The preload should not exceed 8 to 14 in-lb over the original reading, or bearing failure may result).

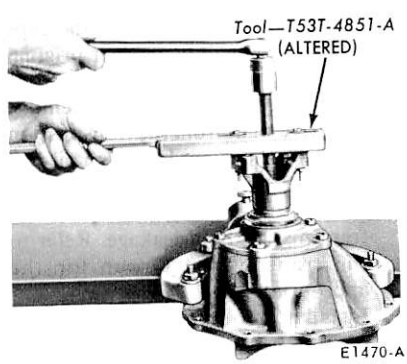

FIG. 11 Removing U-Joint Flange

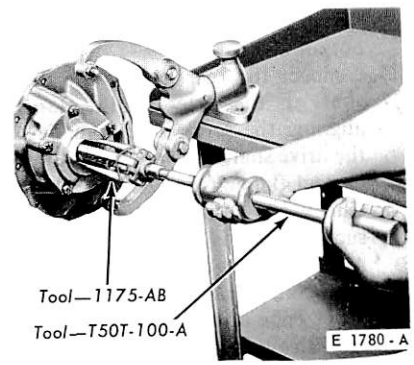

FIG. 12 Removing Pinion Seal

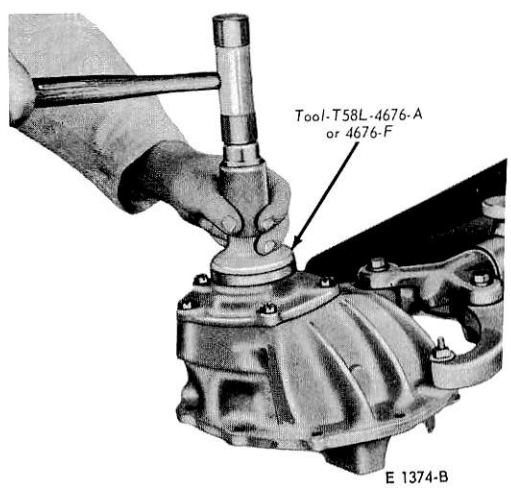

FIG. 13 Installing Pinion Seal

Under no circumstances should the pinion nut be backed off to lessen preload. If this is done, a new pinion bearing spacer must be installed. In addition, the U-joint flange must never be hammered on, or power tools used.

16. Remove the oil seal replacer tool from the transmission extension housing. Install the front end of the

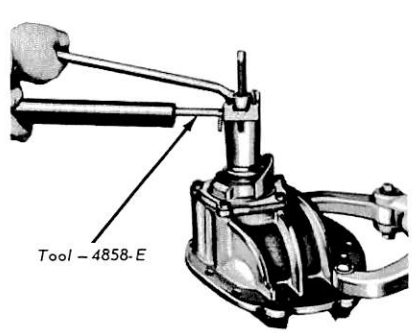

FIG. 14 Installing U-Joint Flange

drive shaft on the transmission output shaft.

17. Connect the rear end of the drive shaft to the axle U-joint flange, aligning the scribe marks made on the drive shaft end yoke and the axle U-joint flange (Fig. 9).
18. Check the lubricant level. **Make sure the axle is in running position. Add whatever amount of specified lubricant is required to reach the lower edge of the filler plug hole if the filler hole is in the cover.**

If the filler hole is in the carrier casting, the lubricant level should be at the bottom of the filler hole.

19. Install the brake drum and the drum attaching nuts.
20. Install the wheels and tires on the drums.

SOLID SPACER

The drive pinion oil seal can be replaced without removing the differential carrier assembly from the axle housing.

1. Make scribe marks on the drive shaft end yoke and the axle U-joint flange to insure proper position of the drive shaft at assembly (Fig. 9). Disconnect the drive shaft from the axle U-joint flange. **Be careful to avoid dropping the loose universal joint bearing cups.** Hold the cups on the spider with tape. Mark the cups so that they will be in their original position in relation to the flange when they are assembled. Remove the drive shaft from the transmission extension housing. Install an oil seal replacer tool in the transmission extension housing to prevent transmission leakage. Refer to the transmission Group for the appropriate tool.
2. Make punch marks on the end of the pinion shaft and the U-joint flange inner surface for realignment. While holding the flange with the tool shown in Fig. 10 remove the integral pinion nut and washer.
3. Clean the pinion bearing retainer around the oil seal. Place a drain pan under the seal, or raise the front of the vehicle higher than the rear.
4. Using the tool shown in Fig. 11 remove the U-joint flange.
5. Using the tool shown in Fig. 12 remove the drive pinion oil seal.
6. Clean the oil seal seat.
7. Install the new seal in the retainer, using the applicable tool shown in Fig. 13.
8. Check splines on the pinion shaft to be sure they are free of burrs. If burrs are evident, remove them with a fine crocus cloth, working in a rotational motion, then wipe clean. Apply a small quantity of lubricant to U-Joint splines.
9. Install the U-joint flange using the tool shown in Fig. 14.
10. Install a new integral attaching nut and washer on the pinion shaft.
11. Tighten the pinion attaching nut, rotating the pinion several times to seat the bearing, then torque the pinion nut to 180-200 ft-lbs. Hold the flange with the tool shown in Fig. 10 while the nut is being tightened.
12. Remove the oil seal replacer tool from the transmission extension housing. Install the front end of the drive shaft on the transmission output shaft.
13. Connect the rear end of the drive shaft to the axle U-joint flange, aligning the scribe marks made on the drive shaft end yoke and the axle U-joint flange (Fig. 9).
14. Check the lubricant level, and add whatever amount of specified lubricant is necessary to reach the lower edge of the filler plug hole. Make sure the axle is in running position when the level is checked.

ORIGINAL U-JOINT FLANGE (IN VEHICLE REMOVAL AND INSTALLATION)

Use procedure as outlined under Drive Pinion Oil Seal Removal and Installation.

Synthetic seals must not be cleaned, soaked or washed in cleaning solvent.

INSTALLATION OF A NEW UNIVERSAL JOINT FLANGE (IN VEHICLE-COLLAPSIBLE SPACER)

1. Raise the vehicle and install safety stands. Remove both rear wheels and brake drums.
2. Disconnect the drive shaft from the axle U-joint flange. **Be careful to avoid dropping the loose universal joint bearing cups. Hold the cups on the spider with tape.** Mark the cups so that they will be in their original position in relation to the flange when they are assembled. Remove the drive shaft from the transmission extension housing. Install an oil seal replacer tool in the transmission extension housing to prevent transmission fluid leakage. Refer to the transmission Group for the appropriate tool.
3. Install a in-lb torque wrench on the pinion nut. Record the torque required to maintain rotation of the pinion shaft through several revolutions.
4. **While holding the flange with the tool shown in Fig. 10, remove the integral pinion nut and washer.**
5. Clean the pinion bearing retainer around the oil seal. Place a drain pan under the seal, or raise the front of the vehicle higher than the rear. **Synthetic seals must not be cleaned, soaked or washed in cleaning solvent.**
6. Using the tool shown in Fig. 11, remove the U-joint flange.
7. Check splines on the pinion shaft to be sure they are free of burrs. If burrs are evident, remove them by using a fine crocus cloth, working in a rotational motion, then wipe clean. Apply a small amount of lubricant to U-joint splines.
8. Install the U-joint flange using the tool shown in Fig. 14.
9. Install a new integral nut and washer on the pinion shaft. (Apply a small amount of lubricant on the washer side of the nut).
10. Hold the flange with the tool shown in Fig. 9 while the nut is being tightened.
11. Tighten the pinion shaft nut, rotating the pinion occasionally to insure proper bearing seating, and take frequent preload readings until the preload is at the original recorded reading established in Step 3.
12. After original preload has been reached, tighten the pinion nut slowly, until an additional preload of 8 to 14 in-lb over the original reading is reached. (The preload should not exceed 8 to 14 in-lb over the original reading, or bearing failure may result.)

Under no circumstances should the pinion nut be backed off to lessen preload. If this is done, a new pinion bearing spacer must be installed. In addition, the U-joint flange must never be hammered on, or power tools used.

13. Remove the oil seal replacer tool from the transmission extension housing. Install the front end of the drive shaft on the transmission output shaft.
14. Connect the rear end of the drive shaft to the axle U-joint flange, aligning the scribe marks made on the drive shaft end yoke and the axle U-joint flange (Fig. 9).
15. Check the lubricant level. **Make sure the axle is in running position. Add whatever amount of specified lubricant is required to reach the lower edge of the filler plug hole if the filler hole is in the cover.**

If the filler hole is in the carrier casting, the lubricant level should be at the bottom of the filler hole.

INSTALLATION OF A NEW UNIVERSAL JOINT FLANGE (IN VEHICLE-SOLID SPACER)

1. Disconnect the drive shaft from the axle U-joint flange. **Be careful to avoid dropping the loose universal joint bearing cups.** Hold the cups on the spider with tape. Mark the cups so that they will be in their original position in relation to the flange when they are assembled. Remove the drive shaft from the transmission extension housing. Install an oil seal replacer tool in the transmission extension housing to prevent transmission leakage. Refer to the transmission Group for the appropriate tool.
2. While holding the flange with the tool shown in Fig. 10, remove the integral pinion nut and washer.
3. Clean the pinion bearing retainer around the oil seal. Place a drain pan under the seal, or raise the front of the vehicle higher than the rear.
4. Using the tool shown in Fig. 11, remove the U-joint flange.
5. Check splines on the pinion shaft to be sure they are free of burrs. If burrs are evident, remove them by using a fine crocus cloth, working in a rotational motion, then wipe clean. Apply a small amount of lubricant to U-joint splines.
6. Install the U-joint flange using the tool shown in Fig. 14.
7. Install integral attaching nut and washer on the pinion shaft.
8. Tighten the pinion attaching nut, rotating the pinion several times to seat the bearing, then torque the pinion attaching nut to 180-220 ft-lbs. Hold the flange with the tool shown in Fig. 11 while the nut is being tightened.
9. Remove the oil seal replacer tool from the transmission extension housing. Install the front end of the drive shaft on the transmission output shaft.
10. Connect the rear end of the drive shaft to the axle U-joint flange.
11. Check the lubricant level, and add whatever amount of specified lubricant is necessary to reach the lower edge of the filler plug hole. Make sure the axle is in running position when the level is checked.

REMOVAL AND INSTALLATION

CARRIER ASSEMBLY

Removal

1. Raise the vehicle on a hoist and remove the two rear wheel and tire assemblies.
2. Remove the two brake drums (3 Tinnerman nuts at each drum) from the axle shaft flange studs. If difficulty is experienced in removing the drums, back off the brake shoes as explained in Part 12-02.
3. **Working through the hole provided in each axle shaft flange, remove the nuts that secure the rear wheel bearing retainer plate. Pull each axle shaft assembly out of the axle housingusing axle shaft remover, Tool 4235-C (Fig. 4). Care must be exercised to prevent damage to oil seal, if so equipped. Any roughing or cutting of the seal element during removal or installation can result in early seal failure.** Install a nut on one of the brake carrier plate attaching bolts to hold the plate to the axle housing after the shaft has been removed. **Whenever a rear axle shaft is replaced, the wheel bearing oil seals must be replaced. Remove the seals with Tool 1175AB.**
4. Make scribe marks on the drive shaft end yoke and the axle U-joint flange to insure proper position at assembly. Disconnect the drive shaft at the rear axle U-joint, remove the drive shaft from the transmission extension housing. Install oil seal replacer Tool T57P-7657-A in the housing to prevent transmission leakage.
5. Place a drain pan under the carrier and housing, remove the carrier attaching nuts, and drain the axle. Remove the carrier assembly from the axle housing.

Installation

1. Synthetic wheel bearing seals must not be cleaned, soaked or washed in cleaning solvent. Clean the axle housing and shafts using kerosene and swabs. To avoid contamination of the grease in the sealed ball bearings, do not allow any quantity of solvent directly on the wheel bearings. Clean the mating surfaces of the axle housing and carrier.
2. Position the differential carrier on the studs in the axle housing using a new gasket between carrier and housing. Install the carrier-to-housing attaching nuts, and torque to specifications.
3. Remove the oil seal replacer tool from the transmission extension housing. Position the drive shaft so that the front U-joint slip yoke splines to the transmission output shaft.
4. Connect the drive shaft to the axle U-joint flange, aligning the scribe marks made on the drive shaft end yoke and the axle U-joint flange during the removal procedure (Fig. 6). Install the U-bolts and nuts and torque to specifications.
5. Wipe a small amount of an oil-resistant sealer on the outer edge of each seal before it is installed. **Do not put any of the sealer on the sealing lip. Install the oil seals in the ends of the rear axle housing with tool shown in Fig. 8.**
6. Install the two axle shaft assemblies in the axle housing. Care must be exercised to prevent damage to the oil seals. The shorter shaft goes into the left side of the housing.

When installing an axle shaft, place a new gasket between the housing flange and the brake backing plate, and carefully slide the axle shaft into the housing so that the rough forging of the shaft will not damage the oil seal. Start the axle splines into the differential side gear, and push the shaft in until the bearing bottoms in the housing.

7. Install the bearing retainer plates on the attaching bolts on the axle housing flanges. Install the nuts on the bolts and torque to specifications.
8. Install the two rear brake drums and the drum attaching nuts.
9. Install the rear wheel and tire assemblies.
10. If the rear brake shoes were backed off, adjust the brakes as outlined in Part 12-01.
11. Fill the rear axle with specified lubricant.

AXLE HOUSING

Removal

1. Remove the carrier assembly from the axle housing as outlined in the foregoing procedure.
2. Position safety stands under the rear frame members, and support the axle housing with either a floor jack or hoist.
3. Disengage the brake line from the clips that retain the line to the axle housing.

4. Disconnect the vent tube from the rear axle housing.
5. Remove the brake backing plate assemblies from the axle housing, and support them with wire. Do not disconnect the brake line.
6. Disconnect each rear shock absorber from the mounting bracket stud on the axle housing.
7. Lower the rear axle slightly to reduce some of the spring tension. At each rear spring, remove the spring clip (U-bolt) nuts, spring clips, and spring seat caps.
8. Remove the rear axle housing from under the vehicle.

Installation

If the axle housing is new, install a new vent. The hose attaching portion must face toward the front of the vehicle.

1. Install new rear wheel bearing oil seals in the ends of the rear axle housing with tools shown in Fig. 8. If leather-type wheel bearing service seals are to be installed, soak the new rear wheel bearing oil seals in SAE 10 oil for 1/2 hour before installation.
2. Position the rear axle housing under the rear springs. Install the spring clips (U-bolts), spring seat caps, and nuts. **Torque the spring clip nuts evenly to specifications.**
3. If a new axle housing is being installed, remove the bolts that attach the carrier plate and bearing retainer from the old housing flanges. Position the bolts in the new housing flanges to hold the brake backing plates in position. Install the backing plates with new gaskets between the housing flange and the brake backing plate.
4. Connect the vent tube to the axle housing.
5. Position the brake line to the axle housing, and secure with the retaining clips.
6. Raise the rear axle housing and springs enough to allow connecting the rear shock absorbers to the mounting bracket studs on the axle housing.
7. Install the carrier assembly and the two axle shaft assemblies in the axle housing as outlined in this section.

DISASSEMBLY AND ASSEMBLY

DISASSEMBLY

After mounting the carrier in a holding fixture, perform the Inspection before Disassembly of Carrier as explained in Part 15-01, under Adjustments. Then disassemble the carrier as outlined in the following procedures. A disassembled view of the rear axle assembly is shown in Fig. 2.

REMOVAL AND DISASSEMBLY OF DIFFERENTIAL CASE

1. Mark one differential bearing cap and the mating bearing support with punch marks to help position the parts properly during assembly of the carrier. Also, mark one of the bearing adjusting nuts and the carrier with scribe marks for proper location during assembly.
2. Remove the adjusting nut locks, bearing caps, and adjusting nuts. Then lift the differential assembly out of the carrier.
3. Remove the differential bearings with the tool shown in Fig. 15.
4. Mark the differential case, cover, and ring gear for assembly in the original position.
5. Remove the bolts that attach the ring gear to the differential case. Press the gear from the case or tap it off with a soft-faced hammer.
6. With a drift drive out the differential pinion shaft lock pin (Fig. 16), and separate the 2-piece differential case.
7. Drive the pinion shaft out with a brass drift (Fig. 17).
8. Remove the gears and thrust washers (Fig. 38).

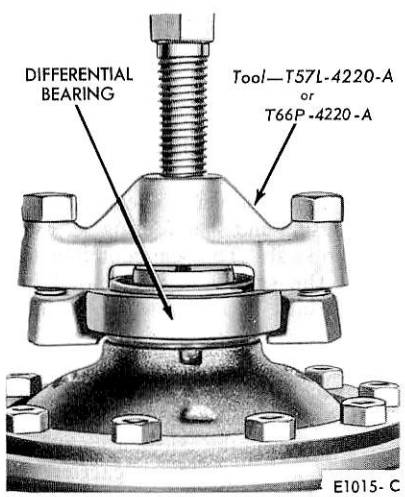

FIG. 15 Removing Differential Bearing

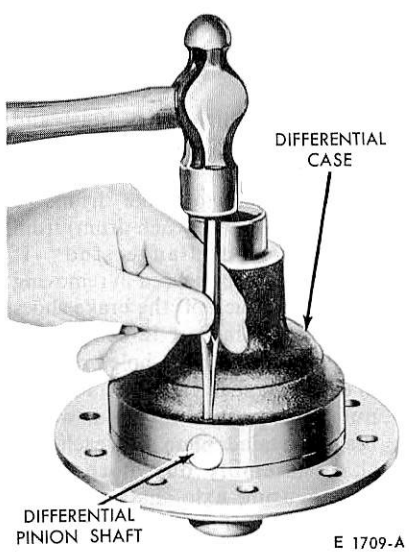

FIG. 16 Removing Differential Pinion Shaft Lock Pin

REMOVAL AND DISASSEMBLY OF DRIVE PINION AND BEARING RETAINER

1. Turn the carrier assembly upright and remove the pinion shaft nut (Fig. 10).
2. Remove the U-joint flange from the pinion shaft (Fig. 11).
3. Remove the pinion seal (Fig. 12).
4. Remove the pinion, bearing, and retainer assembly from the carrier housing (Fig. 30). Measure the shim thickness with a micrometer. Record this original shim thickness. If a new gear set is installed during assembly, a new shim will have to be installed. The original shim thickness is one of the factors necessary in determining the new shim thickness. **Extreme care must be taken not to damage the**

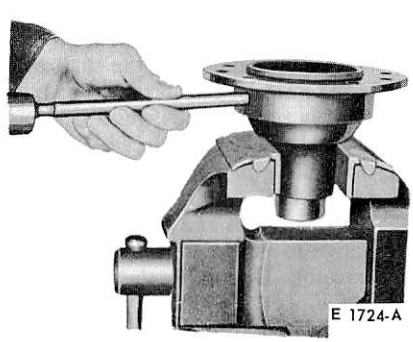

FIG. 17 Driving Out Differential Pinion Shaft

MOUNTING surfaces of the retainer and carrier.

5. Place a protective sleeve (hose) on the pinion pilot bearing surface. Press the pinion shaft out of the pinion front bearing cone (Fig. 18).
6. Press the pinion shaft out of the pinion rear bearing cone (Fig. 19).

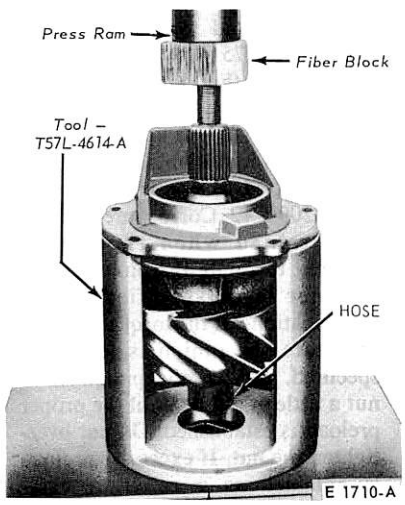

FIG. 18 Removing Pinion Front Bearing Cone

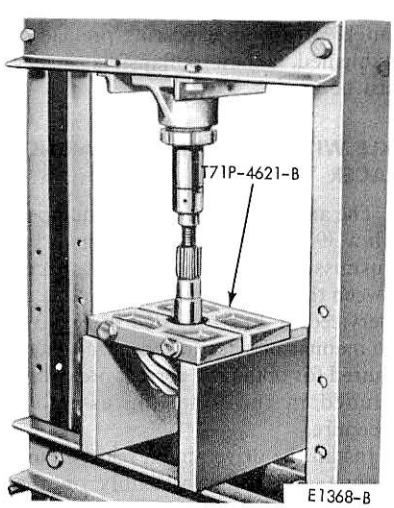

FIG. 19 Removing Pinion Rear Bearing Cone

PARTS REPAIR OR REMOVAL AND INSTALLATION

Clean and inspect all the parts as outlined in Part 15-01, under Adjustments. Before assembling the carrier, repair or remove and install all parts as indicated by the inspection.

The principal replacement operations are covered in the following procedures. All other repair or removal and installation operations are performed during Cleaning and Inspection Part 15-01, Adjustments, or during the Assembly of the Carrier in this Section.

PILOT BEARING

1. Remove the pilot bearing as shown in Fig. 20. Drive out the pilot bearing and the bearing retainer together.
2. Drive the new bearing in until it bottoms as shown in Fig. 21.
3. Using the same tool, install a new pilot bearing retainer with the concave side up.

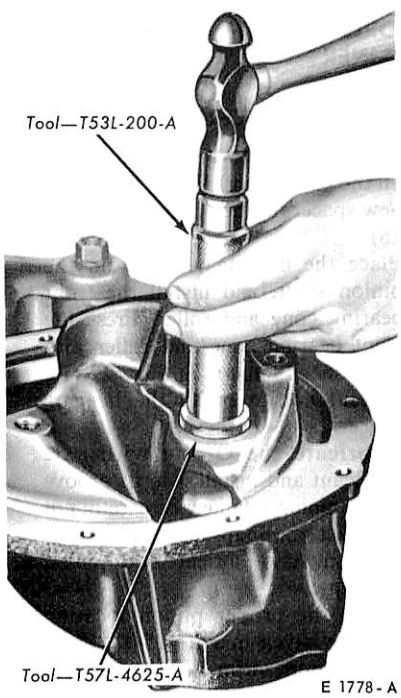

FIG. 20 Removing Pilot Bearing

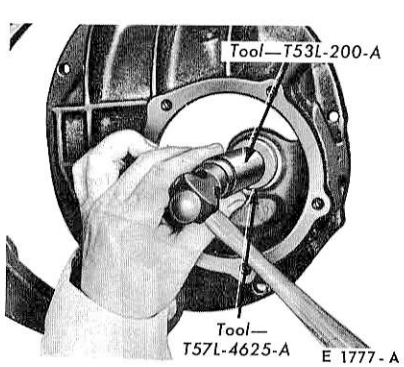

FIG. 21 Installing Pilot Bearing

PINION BEARING CUPS

Do not remove the pinion bearing cups from the retainer unless the cups are worn or damaged. The flange and pilot of the retainer are machined during manufacture by locating on these cups after they are installed in their bores. If the cups are worn or damaged, they should be replaced.

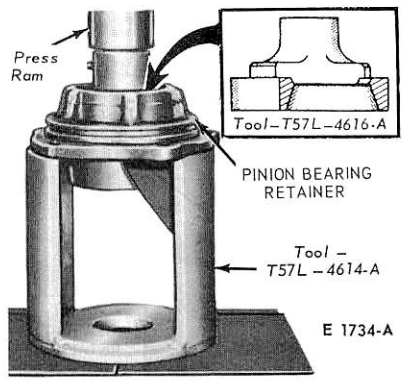

FIG. 22 Removing Pinion Front Bearing Cup

Remove the cups as shown in Figs. 22 and 23.

After the new cups are installed (Figs. 24 and 25), make sure they are seated in the retainer by trying to insert a 0.0015-inch feeler gauge between the cup and the bottom of the bore.

Whenever the cups are replaced, the cone and roller assemblies should also be replaced.

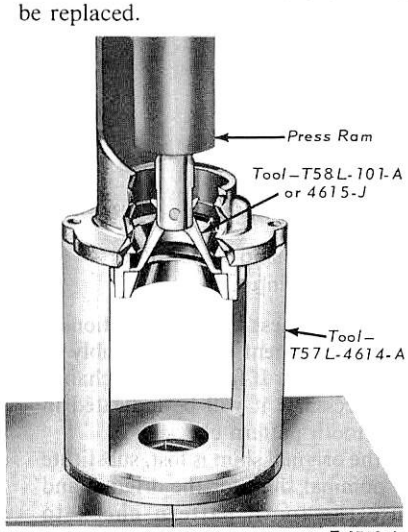

FIG. 23 Removing Pinion Rear Bearing Cup

ASSEMBLY

DRIVE PINION AND RING GEAR SET

When replacing a ring gear and pinion, note that the original factory installed shim is of the correct thickness to adjust for individual variations in both the carrier housing dimension and in the original gear set dimension. Therefore, to select the correct shim thickness for the new gear set to be installed, follow these steps:

1. Use a micrometer to measure the thickness of the original shim removed from the axle and use the

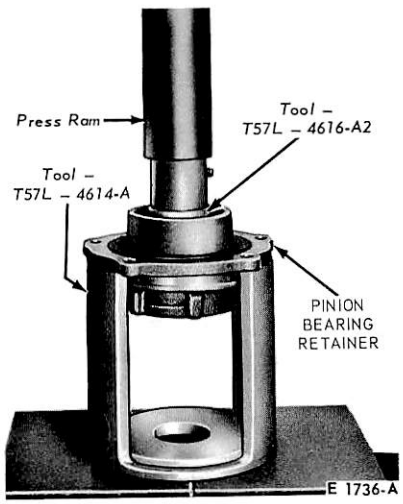

FIG. 24 Installing Pinion Front Bearing Cup

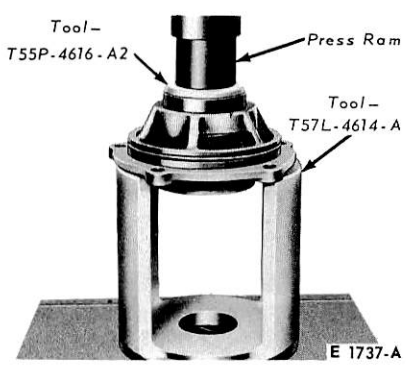

FIG. 25 Installing Pinion Rear Bearing Cup

same thickness upon installation of the replacement carrier assembly or drive pinion. If further shim change is necessary, it will be indicated in the tooth pattern check.

2. If the original shim is lost, substitute a nominal shim for the original and use the tooth pattern check to determine if further shim changes are required. Nominal shim thicknesses is indicated in Specifications.

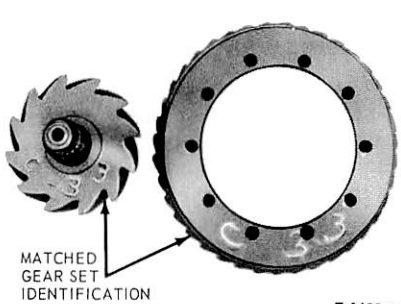

FIG. 26 Pinion and Ring Gear Markings

A new ring gear and pinion should always be installed in an axle as a matched set (never separately). **Be sure the same identifying (matching) number, painted in white, appears on the bolt hole face of the ring gear and on the head of the drive pinion (Fig. 26).**

3. After determining the correct shim thickness as explained in the foregoing steps, install the new pinion and ring gear as outlined under Assembly.

ASSEMBLY AND INSTALLATION OF DRIVE PINION AND BEARING RETAINER

COLLAPSIBLE SPACER

1. Install the pinion rear bearing cone on the pinion shaft (Fig. 27). Place a new spacer on the pinion shaft (Fig. 28).
2. Place the bearing retainer on the pinion shaft, and install the front bearing cone and roller. Press the front bearing cone and roller into position as shown in Fig. 29. Be careful not to crush the bearing spacer.
3. Lubricate the O-ring with axle lubricant and install it in its groove in the pinion retainer. Be careful not to twist it. Snap the O-ring into position. Also lubricate both pinion bearings.
4. Select the proper pinion locating shim as given in Part 15-01. Place the proper shim on the carrier housing and install the pinion and

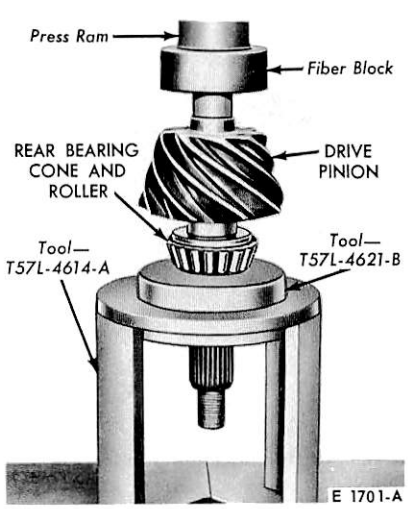

FIG. 27 Installing Pinion Rear Bearing Cone

retainer assembly, being careful not to pinch the O-ring (Fig. 30).

5. Install the pinion retainer attaching bolts. Torque the bolts to specification.
6. Install a new pinion oil seal in the bearing retainer (Fig. 13).
7. Install the U-joint flange (Figs. 14 and 28).
8. Start a new integral nut and washer on the pinion shaft. Apply a small amount of lubricant to the washer side of the nut.
9. Hold the flange with the tool shown in Fig. 10, and torque the pinion shaft nut to 175 ft-lbs. ***Do not exceed* 175 ft-lbs at this time.**
10. Check the pinion bearing preload as shown in Fig. 31. If an in-lb torque wrench is not available Tool 4209-C may be used in combination with Tool 4209-C12. Correct preload will be obtained when the torque required to rotate the pinion in the retainer is as specified in the Specifications. If the torque required to rotate the pinion is less than specified, tighten the pinion shaft nut a little at a time until the proper preload is established. **Do not overtighten the nut. If excessive preload is obtained as a result of overtightening, replace the collapsible bearing spacer.**

Do not back off the pinion shaft nut to establish pinion bearing preload. If the torque on the pinion shaft nut is less than 175 ft-lbs after bearing preload is established, a new collapsible spacer must be used.

AXLE WITH SOLID PINION BEARING SPACER

The axle, used on a vehicle equipped with a 390 CID engine and standard transmission, employs a solid spacer between the pinion bearings. The spacer is serviced in 20 sizes listed in Fig. 31. The manner of selecting the size spacer required for obtaining correct preload is included in the following assembly procedure.

1. Install the drive pinion rear bearing cone and roller assembly on the pinion shaft as shown in Fig. 32.
2. Select a new solid spacer of a larger size (0.485 inch thick), and slide it over the pinion shaft against the rear bearing.

The pinion bearing preload can be accurately measured only when the pinion shaft nut is torqued to 180-220 ft-lbs. If a spacer smaller than required were used, the specified 180-220 ft-lbs torque would damage the bearings. For this reason, the largest spacer should be tried first. Then, if the bearings are too loose, the size of the spacer can be decreased until the correct preload is obtained.

3. Position the bearing retainer and cup assembly on the pinion shaft and

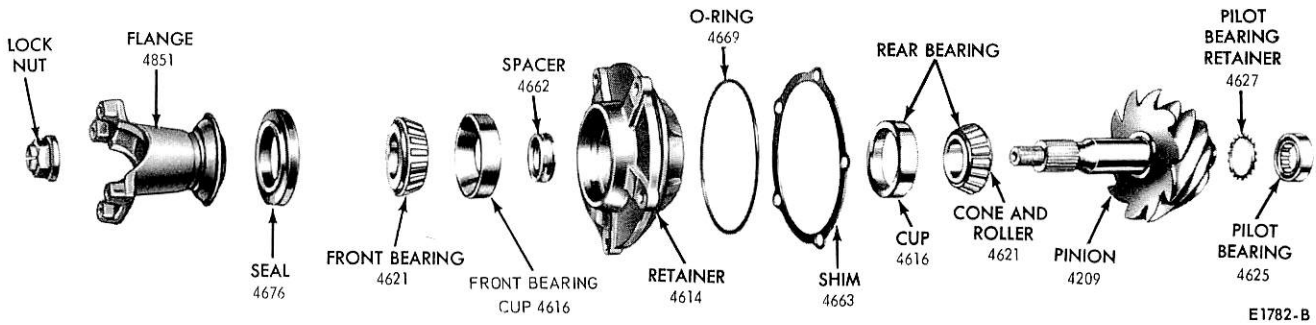

FIG. 28 Pinion and Bearing Retainer

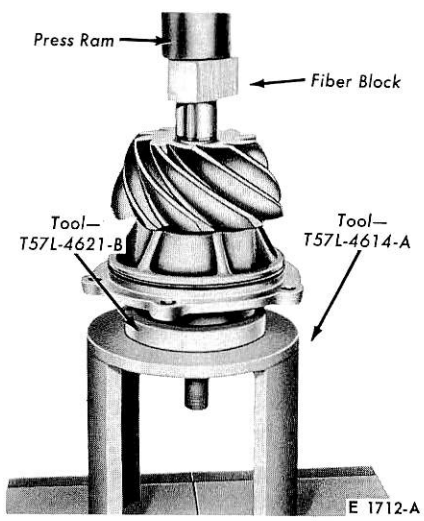

FIG. 29 Installing Pinion Front Bearing

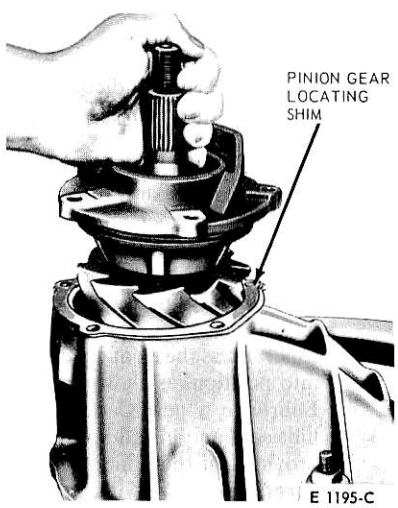

FIG. 30 Removing Or Installing Pinion and Retainer Assembly

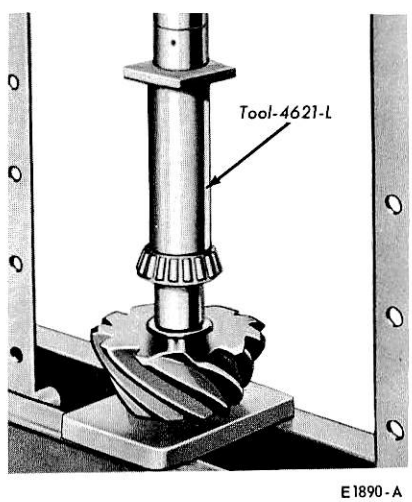

FIG. 32 Installing Pinion Rear Bearing Cone

install the front bearing cone and roller. Press the front cone and roller assembly into position, as shown in Fig. 29.

4. Mount the retainer in a holding fixture as shown in Fig. 33, and place the slinger over the pinion shaft and against the front bearing.
5. Install the U-joint flange with the tool shown in Fig. 14.
6. Hold the flange with the tool shown in Fig. 33, and install the old pinion shaft nut. Using a ft-lb torque wrench, torque the nut to 180-220 ft-lbs. While tightening the nut, rotate the bearing retainer to determine the existence of any bearing preload which will be indicated by a slight drag in the rotation of the retainer.

DETERMINING SPACER SIZE FROM PRELOAD READING

1. If bearing drag indicates a preload condition exists, apply an in-lb torque wrench to the pinion nut as shown in Fig. 34 and read the torque required to turn the shaft. Effort should be 12-1/2 to 32-1/2 in-lbs.
2. If preload is the correct value, proceed with assembly procedure given in Final Assembly of Pinion and Retainer, which follows.
3. If preload exists, but is below specification, select the correct spacer from Fig. 31 and install,

AS END PLAY READS (10/1000 inch) USE THIS SPACER	.0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

CE1950-A

FIG. 31 Solid Spacer Selection

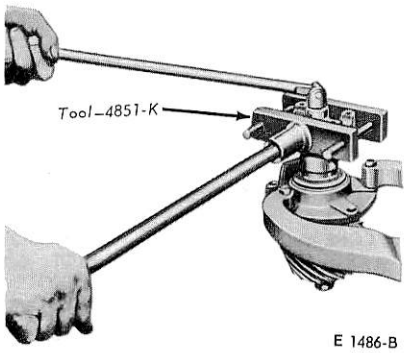

FIG. 33 U-Joint Flange Holding Tool

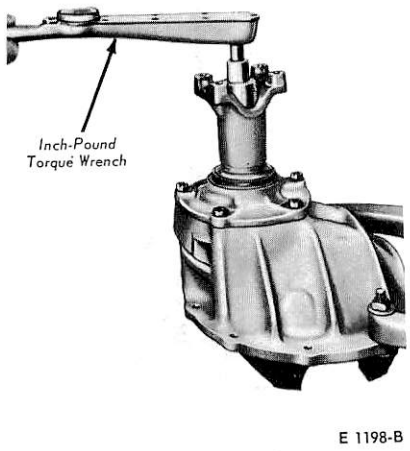

FIG. 34 Pinion Bearing Preload Check

completing assembly as shown in Final Assembly of Pinion and Retainer.

DETERMING SPACER SIZE FROM END PLAY READING

1. If no perceptible preload is felt when rotating the pinion shaft, install a dial indicator as shown in Fig. 35, so that the indicator point is resting on the end of the pinion gear shaft (companion flange end).
2. Use both hands to squeeze the pinion shaft and the bearing retainer together (Fig. 36). Record the end play reading shown on the dial indicator.
3. Disassemble the pinion shaft and retainer and install the correct spacer as shown in Fig. 31.
4. Proceed with assembly of the pinion shaft and retainer as directed in **Final Assembly of Pinion and Retainer.**

FINAL ASSEMBLY OF PINION AND RETAINER

1. Install the drive pinion rear bearing

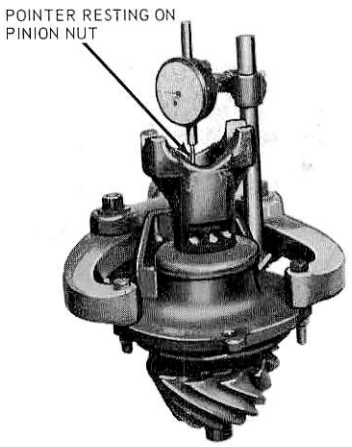

FIG. 35 End Play Indicator Installation

cone and roller assembly on the pinion shaft as shown in Fig. 32.
2. Slide the correct spacer over the pinion shaft against the rear bearing.
3. Position the bearing retainer and cup assembly on the pinion shaft and install the front bearing cone and roller. Press the front cone and roller into position, as shown in Fig. 14.
4. Lubricate a new O-ring with axle lubricant and install it in the groove provided in the pinion retainer. **Be careful not to twist the O-ring. Install it by snapping it into place.**
5. Place the proper shim on the carrier housing and install the pinion and retainer assembly, being careful not to pinch the O-ring (Fig. 30).
6. Install the pinion retainer bolts. Torque the bolts to specification.
7. Place the slinger over the pinion shaft and against the front bearing.
8. Install a seal in the bearing retainer, (Fig. 37).

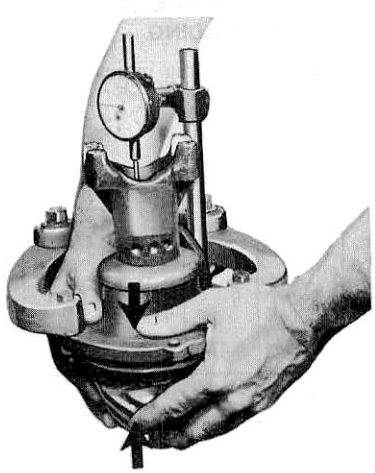

FIG. 36 Checking Pinion End Play

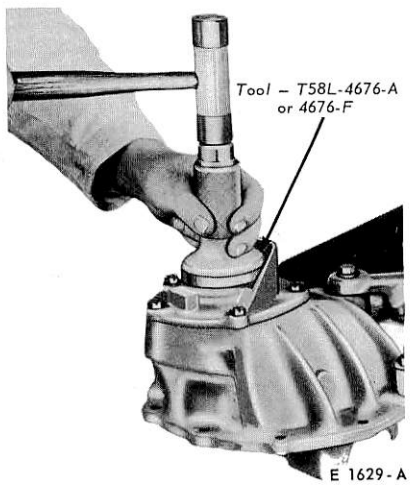

FIG. 37 Installing Oil Seal

9. Start a new integral nut and washer on the pinion shaft.
10. Hold the companion flange with the tool shown in Fig. 33 and torque the pinion nut to specifications (200 ft-lbs).
11. With a new seal installed, pinion bearing preload should now read 17 to 32 in-lbs for new pinion bearings and new seal, or 8 to 14 in-lbs for original bearings and a new seal.

ASSEMBLY AND INSTALLATION OF DIFFERENTIAL CASE

1. Place a side gear thrust washer in the differential case bore (Fig. 38). **Lubricate all differential parts liberally with axle lubricant during assembly.**
2. With a soft-faced hammer, drive the pinion shaft into the case only far enough to retain a pinion thrust washer and pinion gear.
3. Place the second pinion and thrust washer in position, and drive the pinion shaft into place. **Carefully line up the pinion shaft lock pin holes.**
4. Place the second side gear and thrust washer in position (Fig. 38), and install the cover on the differential case. Install the pinion shaft lock pin. A pinion or axle shaft spline can be inserted in the side gear spline to check for free rotation of the differential gears.
5. Insert tow 7/16 (N.F.) bolts two inches long through the differential case flange, and thread them three or four turns into the ring gear as a guide in aligning the ring gear bolt holes. Press or tap the ring gear into position.
6. Install and tighten the ring gear bolts evenly, and torque them alternately across the gear to

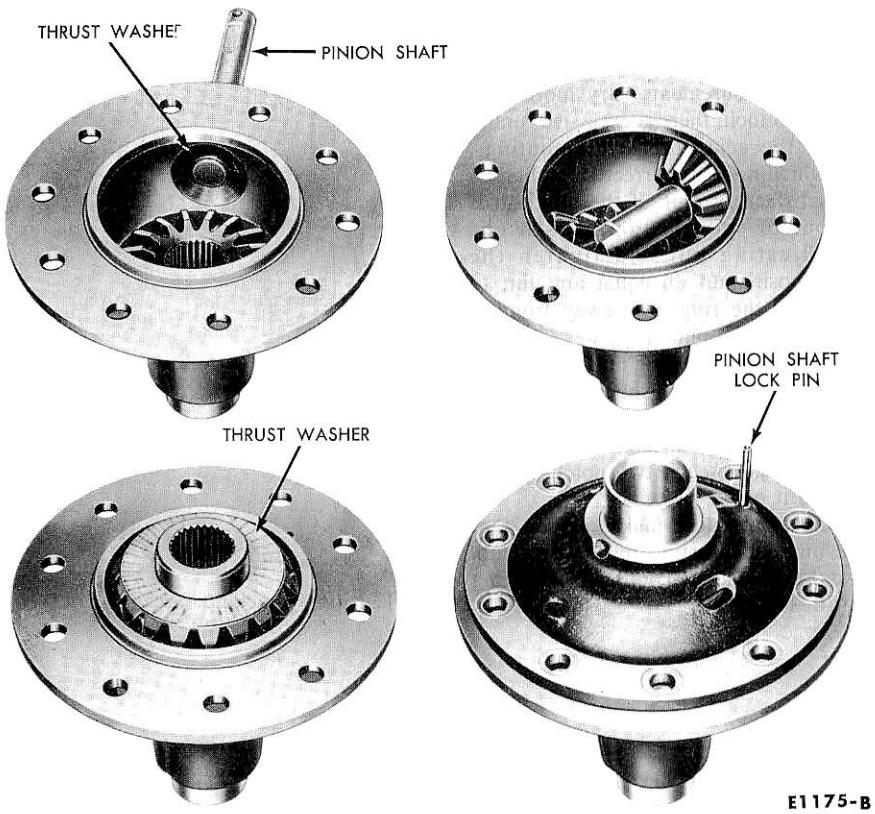

FIG. 38 Assembly of Differential Case

specification.

7. If the differential bearings have been removed, press them on as shown in Fig. 39.
8. Apply a thin coating of lubricant on the bearing bores in the carrier so that the differential bearing cups will move easily. Place the cups on the bearings and set the differential case assembly in the carrier.
9. Slide the assembly along the bores until a slight amount of backlash is felt between the gear teeth.
10. Set the adjusting nuts in the bores so that they just contact the bearing cups. The nuts should be engaged about the same number of threads on each side.
11. Carefully position the bearing caps on the carrier. Match the marks made when the caps were removed.
12. Install the bearing cap bolts and alternately torque them to 70-80 ft-lbs.
13. If the adjusting nuts do not turn freely as the cap bolts are tightened, remove the bearing caps and again inspect for damaged threads or incorrectly positioned caps. Tightening the bolts to the specified torque is done to be sure that the cups and adjusting nuts are seated.
14. Adjust the backlash between the ring gear and pinion and the differential bearing preload as outlined in the following procedure.

BACKLASH AND DIFFERENTIAL BEARING PRELOAD ADJUSTMENT

1. Loosen the cap bolts, then tighten them to only 35 ft-lbs torque before making adjustments. **The left adjusting nut is onthe ring gear side of the carrier. The right nut is on the pinion side. Tightening the left nut moves the ring gear into the pinion to decrease backlash, and tightening the right nut moves the ring gear away.**
2. Loosen the right nut until it is away from the cup (Fig. 40). Tighten the left nut until the ring gear is just forced into the pinion with no backlash. (Recheck the right nut at this time to be sure it is still loose). Tighten the right nut two notches

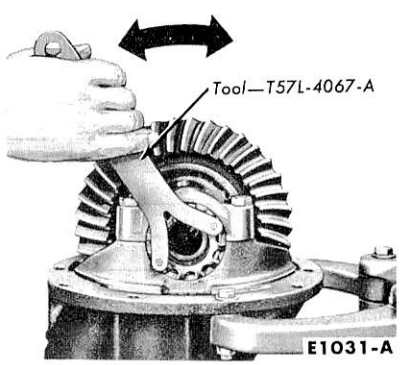

FIG. 40 Backlash Adjustments

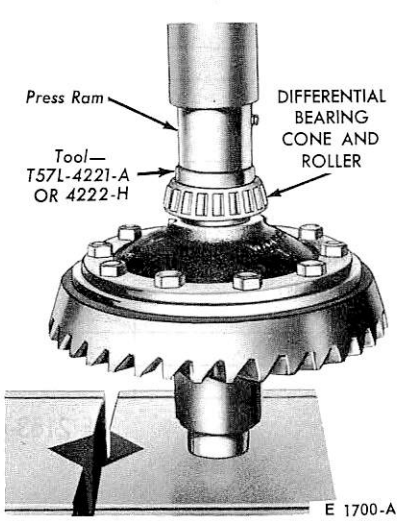

FIG. 39 Installing Differential Bearing

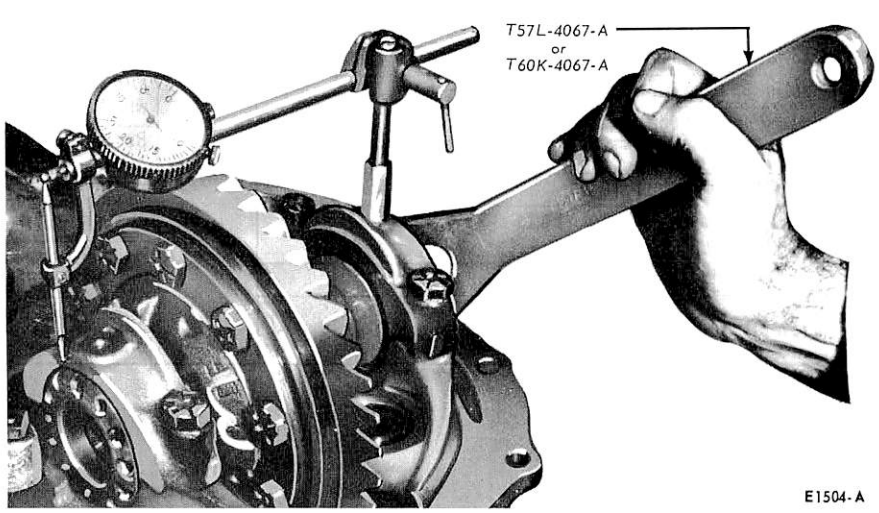

FIG. 41 Adjusting Side Bearing Preload

beyond the position where it first contacts the bearing cup. Rotate the ring gear several revolutions in each direction while the bearings are loaded to seat the bearings in their cups. **This step is important.**

3. Again loosen the right nut to release the preload. If there is any backlash between the gears, tighten the left nut just enough to remove this backlash. Install a dial indicator (Fig. 41) and carefully tighten the right nut until it just contacts the cup. Set preload of 0.008 to 0.012 for new bearings and .005 to .008 for used bearings by spreading the case using the right nut. As preload is applied from the right-hand side, the ring gear is forced away from the pinion and usually results in the correct backlash. The specified backlash for all gears is 0.008 to 0.012 inch. Tighten the differential cap bolts to the specified 75-80 ft-lbs torque.
4. Measure the backlash as shown in Fig. 42. Measure the backlash on several teeth around the ring gear. If the measurements vary more than 0.003 inch, there is excessive runout in the gears or their mountings, which must be corrected to obtain a satisfactory unit. If the backlash is out of specification, loosen one adjusting nut and tighten the opposite nut an equal amount, to move the ring gear away from or toward the pinion.

   When the adjusting nuts are moved, the final movement should always be made in a tightening direction. For example, if one nut has to be loosened one notch, loosen it two notches; then tighten it one.

   This procedure makes certain that the nut is contacting the bearing cup, and that the cup will not shift after being put in service.
5. Check the gear tooth contact as outlined in Specifications.

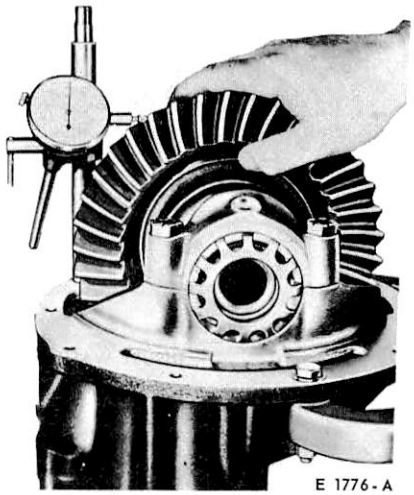

FIG. 42 Checking Backlash

DESCRIPTION

Eaton Standard single-speed, single-reduction axles are installed as standard equipment on 500-9000 Series trucks. These axles are also used as the rearward rear axles on tandem single-speed, single-reduction units.

Since all of these axles are of the same basic design, the procedures given in this part apply to all unless otherwise noted.

DESCRIPTION

The axles are equipped with a straddle-mounted pinion. The opposed tapered-roller pinion bearings are press-fit installed on the drive pinion shaft. The straight-roller pilot bearing is pressed onto the inner end of the pinion (Fig. 1).

Shims of various thicknesses are installed between the pinion bearing retainer and the carrier housing. These shims provide a means for adjusting the pinion depth.

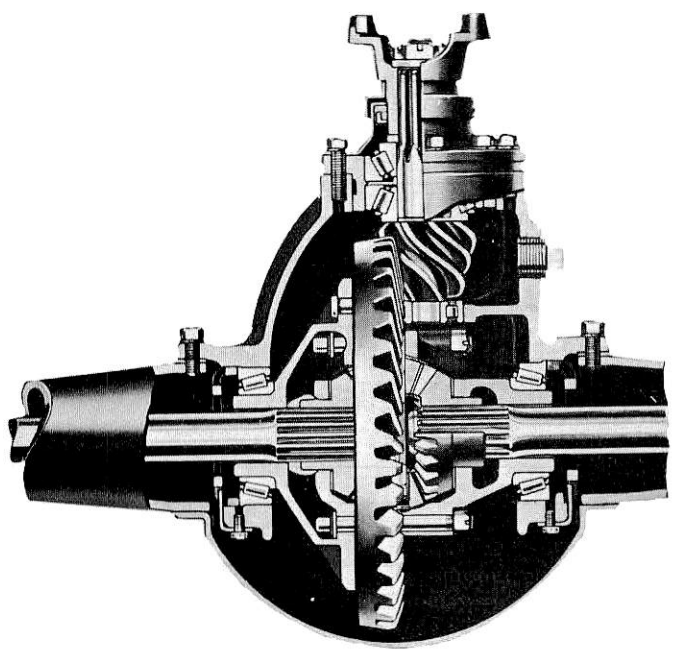
A spacer is installed between the inner and outer drive pinion bearings. This spacer is available in several thicknesses and is used to adjust the pinion bearing preload.

The four-pinion differential assembly is mounted in a two-piece case.

The tapered-roller differential side bearings are pressed onto the differential case hubs. The bearing cups are retained by the side bearing adjusters and by the side bearing caps. The side bearing adjusters thread into the bores formed by the bearing caps and the differential supports.

The axle shafts are full-floating, with the inner ends splined to the differential side gears. The axle shaft flanges are attached to the hubs with studs, lock washers, and nuts. The stud holes in the axle shaft flanges are taper reamed for the installation of split tapered dowels.

The differential carrier assembly may be removed while the axle is still installed in the vehicle.



E2206-A

FIG. 1 Single-Speed Single-Reduction Axle

ADJUSTMENTS

Axle shafts, wheel hubs, wheel hub bearings, wheel hub grease seals, and the drive pinion oil seal can be replaced without removing the differential carrier assembly from the rear axle or the rear axle from the vehicle.

To lubricate, adjust, or replace the rear axle shafts, rear wheel hubs, bearings or grease seals, refer to Part 11-14.

DRIVE PINION OIL SEAL REMOVAL AND INSTALLATION

1. Disconnect the drive shaft from the rear universal joint pinion flange.
2. Hold the universal joint flange with the tool listed in Specifications. Remove the cotter pin, nut, and washer from the drive pinion shaft (Fig. 5).
3. Remove the flange using the tool listed in Specifications. Remove the bolts, which attach the oil seal retainer and pinion bearing retainer to the carrier. Remove the oil seal retainer and gasket.
4. Using the tool listed in Specifications, remove the oil seal from the retainer.
5. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the oil seal retainer (Fig. 2). Apply a light coat of Lubriplate or similar lubricant to the contact areas of the seal and the pinion shaft.
6. Position the oil seal retainer and a new gasket against the pinion bearing retainer (Fig. 5 and 6). Install the bolts that attach the oil seal retainer and pinion bearing retainer to the differential carrier assembly and torque the bolts to specifications.
7. Install the universal joint flange, nut and washer using Tool-4851-A. Torque the nut to specifications and install the cotter pin.
8. Connect the drive shaft to the rear universal joint flange.
9. Check the lubricant level and fill if necessary as described under Adjustments in Part 15-01. Use the lubricant specified.

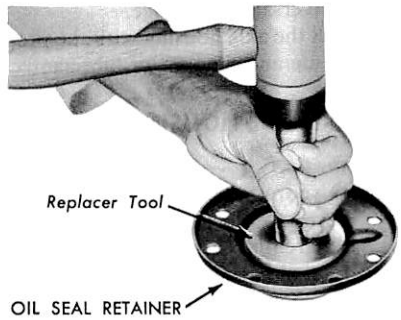


FIG. 2 Installing Drive Pinion Oil Seal

REMOVAL AND INSTALLATION

DIFFERENTIAL CARRIER

Removal

1. Drain and discard the axle lubricant.
2. Remove the axle shaft, stud nuts and lock washers.

If tapered dowels are installed in the axle shaft flange, hold a short drift firmly in the center of the axle shaft flange, and then strike it sharply to loosen the dowels. Remove the dowels and then remove the axle shaft.

Tapered dowels are not used at the axle shaft flange on most of the larger trucks. On these flanges, two puller threads are provided. Use one or both puller threads to remove the axle shafts (Refer to part 15-01).

3. Disconnect the drive shaft at the rear universal joint pinion flange.
4. Support the carrier assembly properly with a roller jack (Fig. 3). Then remove the carrier to housing stud nuts or bolts and lock washers.
5. Tighten the puller screws, when provided in the carrier, until the carrier is loosened from the housing. Carefully withdraw the carrier assembly from the axle housing, then back off the puller screws. Remove and discard the axle housing gasket.
6. Position the carrier on a transmission stand (Fig. 4) or in the open end of an oil drum approximately the same diameter as the carrier.

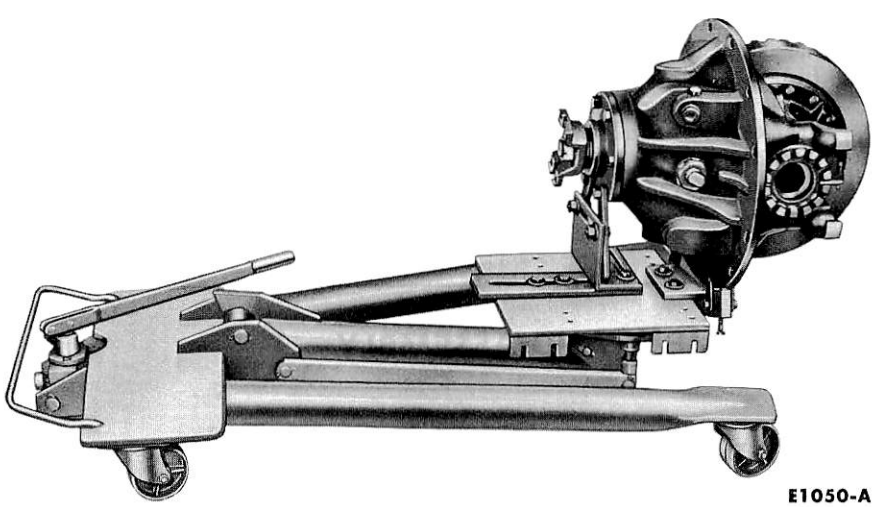

FIG. 3 Typical Differential Carrier Jack

Installation

1. Place a new carrier-to-housing gasket on the axle housing. **A dry gasket will prevent creeping between carrier and housing under heavy loads.**
2. Place the differential carrier assembly on a roller jack, and roll the carrier into position. Start the carrier into the housing with four capscrews (or stud nuts) equally spaced.
3. Tighten the capscrews (or nuts) alternately to draw the carrier squarely into the housing. Install the remaining carrier to housing lock washers and cap screws (or nuts), then torque to specification.
4. Install new gaskets on the wheel hubs, then install the axle shafts. Install the dowels, lock washers and stud nuts. Torque the nuts to specification.
5. Connect the drive shaft at the rear

universal joint flange.
6. Fill the axle housing with the proper grade and amount of lubricant.

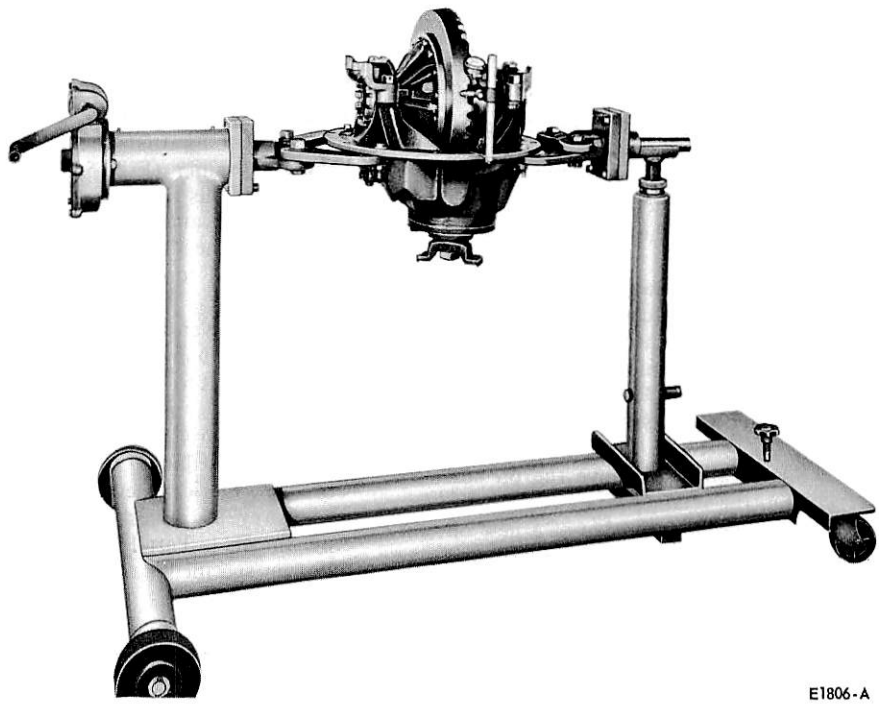
REAR AXLE HOUSING

Removal

1. Disconnect the drive shaft and remove the axle shafts and differential carrier as outlined in the foregoing procedure.
2. Disconnect the rear shock absorbers from the spring seal caps or shock absorber brackets. Then raise the rear end of the vehicle frame until the weight is off the rear springs. Place safety stands under the frame in this position.
3. Disconnect the flexible hydraulic brake hose or air lines at the frame or frame crossmember.
4. Remove the nuts from the spring clips (U-bolts), and remove the spring seat caps and shock absorber brackets.
5. Roll the axle housing and rear wheels from underneath the vehicle.
6. Remove the wheels from the axle housing.

Installation

1. After installing the rear wheels, roll the axle assembly under the truck.
2. Install the spring clips (U-bolts), spring seat caps and shock absorber brackets. Torque the nuts to specifications.
3. Connect the rear shock absorbers.
4. Connect the hydraulic brake hose and bleed the brakes. If the axle is equipped with air brakes, connect the air lines.
5. Lower the vehicle to the floor. Install the differential carrier and axle shafts, and connect the drive shaft to the rear U-joint flange as outlined in the Removal procedure under Differential Carrier.



E1806-A

FIG. 4 Typical Differential Carrier Repair Stand

DISASSEMBLY AND ASSEMBLY

DIFFERENTIAL CARRIER

Disassembly

1. Inspect the axle before disassembly as given in Part 15-01.
2. Remove the oil distributor pipe plug, spring and the oil distributor from the carrier, if so equipped (Fig. 5).
3. Loosen the thrust block lock nut and screws, if so equipped, and then back out the clearance between thrust block and ring gear.
4. Mark one differential bearing cap and the corresponding carrier leg with a punch. These marks are to be used as a guide when installing the bearing caps.
5. Remove the adjuster locks.
6. Remove the bearing cap bolts and the bearing caps. Then lift the differential assembly out of the carrier.
7. Clamp the assembly in a vise equipped with soft jaws. Then remove the differential side bearings with a suitable puller.
8. Mark the differential case halves with a punch before disassembling, as this will aid in aligning the case when reassembling. Remove the bolts or capscrews.
9. Separate the case halves, using a brass hammer if necessary, then remove the side gears, spider, pinions and thrust washers.
10. While holding the drive pinion shaft stationary at the flange, remove the cotter pin, nut and washer from the drive pinion shaft.
11. Remove the flange using Tool T65L-4851-A or a suitable puller. Remove the bolts, which attach the oil seal retainer and pinion bearing retainer to the carrier (Fig. 5). Remove the oil seal retainer.
12. Drive the pinion shaft assembly out from the rear.
13. With a micrometer, measure the shim or shims which were installed between the pinion bearing retainer and the carrier housing.
14. Press the pinion out of the front pinion bearing and bearing retainer. Press the rear bearing and spacer off the pinion shaft (Fig. 6).
15. With a micrometer, measure the pinion bearing spacer thickness.
16. Press the pilot bearing off the shaft.
17. If the pinion bearing cups are to be replaced, press them out as shown in Fig. 7.
18. Clean and inspect the parts as given

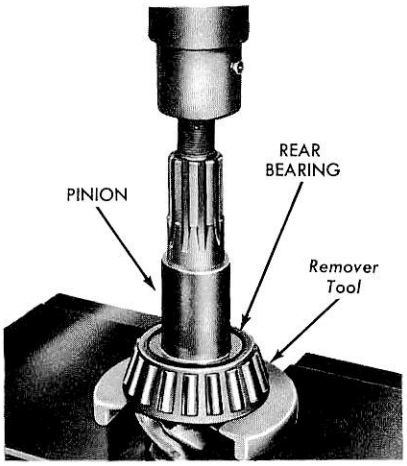


FIG. 6 Removing Pinion Rear Bearing Cone

in Part 15-01.

Assembly

1. Press the pinion pilot bearing on the pinion shaft. Stake the pinion shaft end in 4 places to hold the pilot bearing on (Fig. 8).
2. Press the pinion rear bearing on the shaft until seated against the back face of the pinion gear.
3. Press the pinion bearing cups in the bearing retainer (Fig. 9).
4. Install the pinion in the bearing retainer. Place the old spacer on the pinion shaft for a trial build-up. Install the pinion front bearing. Adjust and check the bearing preload as given in Part 15-01. Preload should be 15-35 in-lbs at correct torque on pinion bearing preload.
5. After the pinion bearing preload is adjusted, install a new oil seal. Install the gasket between the bearing retainer and the oil seal retainer. Install the universal joint flange.
6. If the pinion and ring gear set is being changed, adjust the shim thickness as given in Part 15-01.
7. Install the pinion and retainer assembly in the carrier housing using the correct shims. Install the capscrews, which attach the bearing retainer to the carrier housing. Torque the capscrews to specification.
8. If the ring gear is to be replaced, see Part 15-01, for the correct procedure.
9. Apply a coating of rear axle lubricant on the spider, pinions, side gears, and thrust washers, then assemble them in the ring gear half of the case. Align the punch marks and install the other half of the case. Install the retaining capscrews or the bolts and nuts, and torque to specification. Install the lock wire. Press the differential bearings on the case (Fig. 10).
10. Install the differential assembly and adjust the gear backlash and bearing preload as given in Part 15-01.
11. When the backlash and bearing preload are within limits, check the gear tooth contact pattern (Part 15-01).
12. Tighten the thrust block screw, if so equipped, until the thrust block touches the ring gear. Back off the screw at least 1/6 turn but not more than 1/4 turn to provide the proper clearance between the block and the ring gear. Tighten the lock nut while holding the screw in this position.
13. Install the oil distributor, if so equipped.

DESCRIPTION

Rockwell Standard single-speed, single-reduction axles are installed as standard equipment on 500-9000 Series trucks. These axles are also used as the rearward rear axles on tandem single-speed, single-reduction units.

Since all of these axles are of the same basic design, the procedures given in this part apply to all unless otherwise noted.

DESCRIPTION

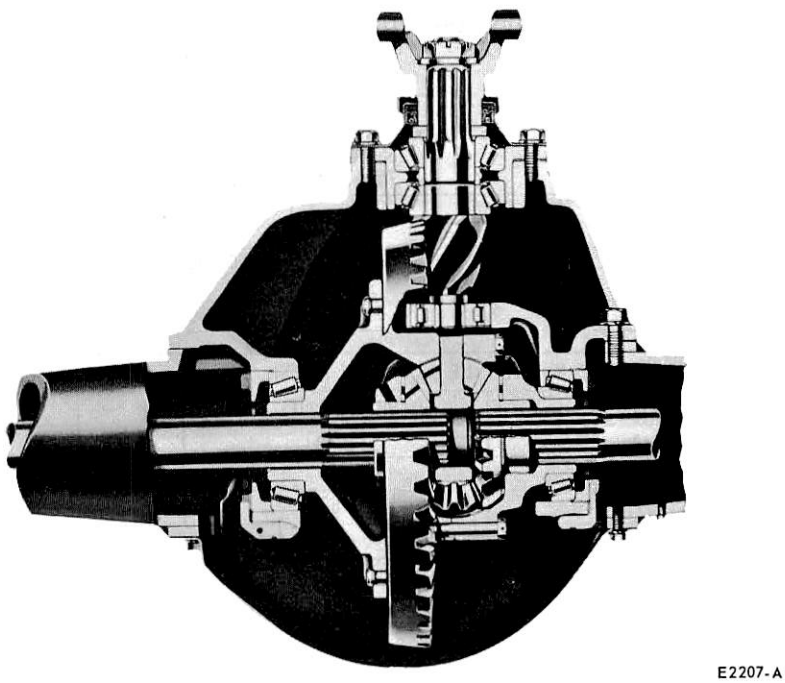
The axles are equipped with a straddle-mounted pinion. The opposed tapered-roller pinion bearings are press-fit installed on the drive pinion shaft. The straight-roller pilot bearing is pressed onto the inner end of the pinion (Fig. 1).

Shims of various thicknesses are installed between the pinion bearing retainer and the carrier housing. These shims provide a means for adjusting the pinion depth.

A spacer is installed between the inner and outer drive pinion bearings. This spacer is available in several thicknesses and is used to adjust the pinion bearing preload.

The four-pinion differential assembly is mounted in a two-piece case.

The tapered-roller differential side bearings are pressed onto the differential case hubs. The bearing cups are retained by the side bearing adjusters and by the side bearing caps. The side bearing adjusters thread into the bores formed by the bearing caps and the differential supports.



E2207-A

FIG. 1 Typical Single-Speed Single-Reduction Axles

The axle shafts are full-floating, with the inner ends splined to the differential side gears. The axle shaft flanges are attached to the hubs with studs, lock washers, and nuts. The stud holes in the axle shaft flanges are taper reamed for the installation of split tapered dowels.

The differential carrier assembly may be removed while the axle is still installed in the vehicle.

ADJUSTMENTS

Axle shafts, wheel hubs, wheel hub bearings, wheel hub grease seals, and the drive pinion oil seal can be replaced without removing the differential carrier assembly from the rear axle or the rear axle from the vehicle.

To lubricate, adjust, or replace the rear axle shafts, rear wheel hubs, bearings or grease seals, refer to Part 11-14.

DRIVE PINION OIL SEAL REMOVAL AND INSTALLATION

1. Disconnect the drive shaft from the rear universal joint pinion flange.
2. Hold the universal joint flange with the tool listed in Specifications. Remove the cotter pin, nut, and washer from the drive pinion shaft (Fig. 5).
3. Remove the flange using the tool listed in Specifications. Remove the bolts, which attach the oil seal retainer and pinion bearing retainer to the carrier. Remove the oil seal retainer and gasket.
4. Using the tool listed in Specifications, remove the oil seal from the retainer.
5. Coat the outside edge of a new oil seal with an oil-resistant sealer and press it into the oil seal retainer (Fig. 2). Apply a light coat of Lubriplate or similar lubricant to the contact areas of the seal and the pinion shaft.
6. Position the oil seal retainer and a new gasket against the pinion bearing retainer (Figs. 5 and 6). Install the bolts that attach the oil seal retainer and pinion bearing retainer to the differential carrier assembly and torque the bolts to specifications.
7. Install the universal joint flange, nut and washer using Tool-4851-A. Torque the nut to specifications and install the cotter pin.
8. Connect the drive shaft to the rear universal joint flange.
9. Check the lubricant level and fill if necessary as described under Adjustments in Part 15-01. Use the lubricant specified.

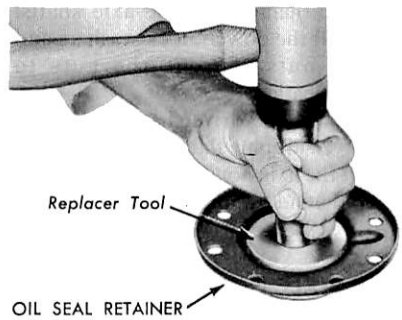


FIG. 2 Installing Drive Pinion Oil Seal

REMOVAL AND INSTALLATION

DIFFERENTIAL CARRIER

Removal

1. Drain and discard the axle lubricant.
2. Remove the axle shaft, stud nuts and lock washers.

If tapered dowels are installed in the axle shaft flange, loosen the dowels by holding a 1 1/2 inch diameter brass drift against the center of the axle shaft head, inside the circular driving lugs. Strike the drift a sharp blow with a 5 to 6 pound hammer or sledge. A 1 1/2 inch diameter brass hammer is an excellent and safe drift. **Do not hit the circular driving lugs on the shaft head. This could cause the lugs to shatter and splinter. Do not use chisels or wedges to loosen the shaft or dowels; this will damage the hub, shaft and oil seal.** Remove the dowels and then remove the axle shaft.

Tapered dowels are not used at the axle shaft flange on most of the larger trucks. On these flanges, two puller threads are provided. Use one or both puller threads to remove the axle shafts (Refer to Part 15-01).

3. Disconnect the drive shaft at the rear universal joint pinion flange.
4. Support the carrier assembly properly with a roller jack (Fig. 3). Then remove the carrier to housing stud nuts or bolts and lock washers.
5. Tighten the puller screws, when provided in the carrier, until the carrier is loosened from the housing. Carefully withdraw the carrier assembly from the axle housing, then back off the puller screws. Remove and discard the axle housing gasket.
6. Position the carrier on a transmission stand (Fig. 4).

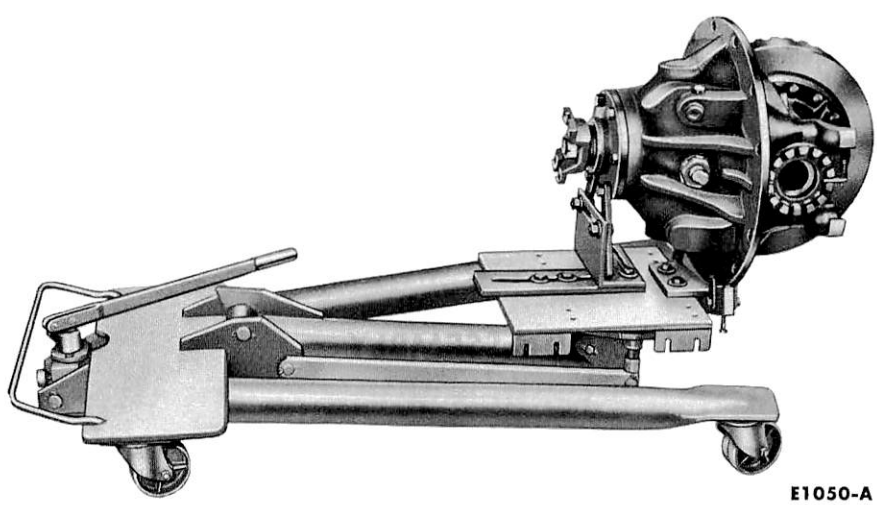

FIG. 3 Typical Differential Carrier Jack

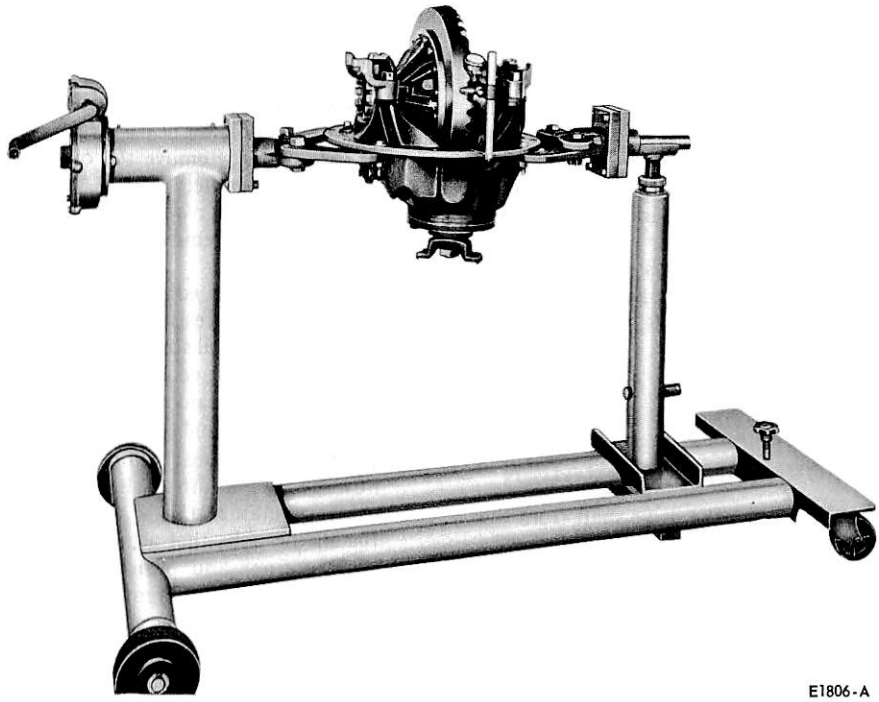
Installation

1. Place a new carrier-to-housing gasket on the axle housing. **A dry gasket will prevent creeping between carrier and housing under heavy loads.**
2. Place the differential carrier assembly on a roller jack, and roll

the carrier into position. Start the carrier into the housing with four capscrews (or stud nuts) equally spaced.
3. Tighten the capscrews (or nuts) alternately to draw the carrier squarely into the housing. Install the remaining carrier to housing lock washers and capscrews (or nuts), then torque to specification.
4. Install new gaskets on the wheel hubs, then install the axle shafts. Install the dowels, lock washers and stud nuts. Torque the nuts to specification.
5. Connect the drive shaft at the rear universal joint flange.
6. Fill the axle housing with the proper grade and amount of lubricant.

REAR AXLE HOUSING

Removal
1. Disconnect the drive shaft.
2. Disconnect the rear shock absorbers from the spring seal caps or shock absorber brackets. Then raise the rear end of the vehicle frame until the weight is off the rear springs. Place safety stands under the frame in this position.
3. Disconnect the flexible hydraulic brake hose or air lines at the frame or frame crossmember.
4. Remove the nuts from the spring clips (U-bolts), and remove the spring seat caps and shock absorber brackets.
5. Roll the axle housing and rear wheels from underneath the vehicle. Remove the axle shafts and differential carrier as outlined in the foregoing procedure.
6. Remove the wheels from the axle housing.



E1806-A

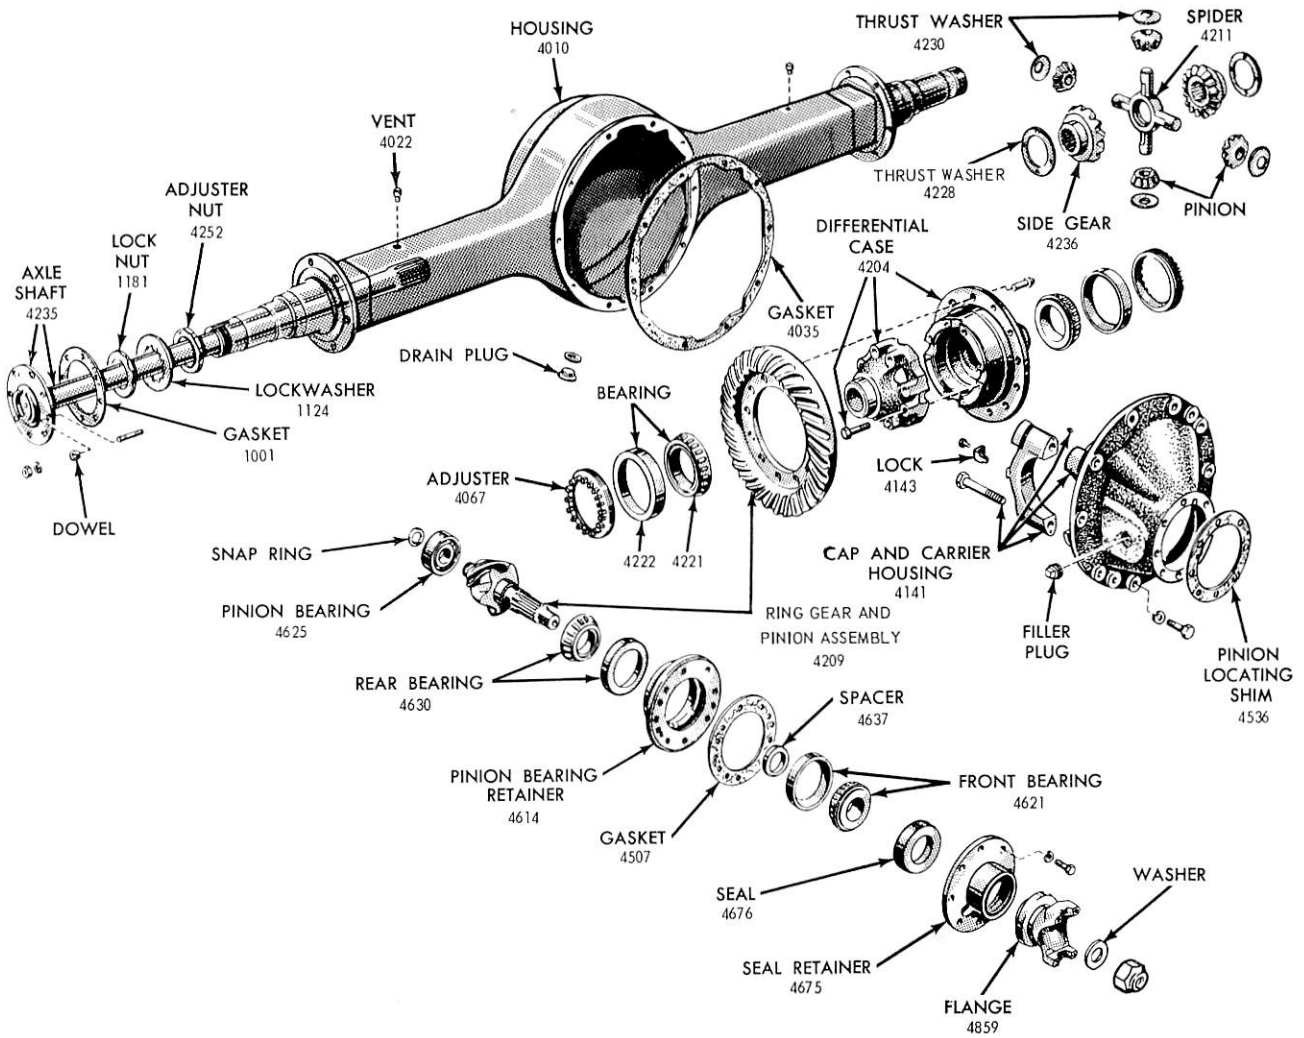
FIG. 4 Typical Differential Carrier Repair Stand

Installation
1. After installing the rear wheels, the axle shafts and the differential carrier, roll the axle assembly under the truck.
2. Install the spring clips (U-bolts), spring seat caps and shock absorber brackets. Torque the nuts to specifications.
3. Connect the rear shock absorbers.
4. Connect the hydraulic brake hose and bleed the brakes. If the axle is equipped with air brakes, connect the air lines.
5. Lower the vehicle to the floor. Install the differential carrier and axle shafts, and connect the drive shaft to the rear U-joint flange as outlined in the Removal procedure under Differential Carrier.

DISASSEMBLY AND ASSEMBLY

DIFFERENTIAL CARRIER

Disassembly
1. Inspect the axle before disassembly as given in Part 15-01.
2. Remove the oil distributor pipe plug, spring and the oil distributor from the carrier, if so equipped (Figs. 5 and 6).
3. Loosen the thrust block lock nut and screws, if so equipped, and then back out the thrust screw to provide clearance between the thrust block and ring gear when the differential is removed.
4. Mark one differential bearing cap and the corresponding carrier leg with a punch. These marks are to be used as a guide when installing the bearing caps.
5. Remove the adjuster locks.
6. Remove the bearing cap bolts and the bearing caps. Then lift the differential assembly out of the carrier.
7. Clamp the assembly in a vise equipped with soft jaws. Then remove the differential side bearings with a suitable puller.
8. Mark the differential case halves with a punch before disassembling, as this will aid in aligning the case when reassembling. Remove the bolts or capscrews.
9. Separate the case halves, using a brass hammer if necessary, then remove the side gears, spider, pinions and thrust washers.
10. While holding the drive pinion shaft stationary at the flange, remove the cotter pin, nut and washer from the drive pinion shaft.
11. **Remove the flange using Tool T65L-4851-A or a suitable puller. Remove the bolts, which attach the oil seal retainer and pinion bearing retainer to the carrier (Fig. 5). Remove the oil seal retainer.**



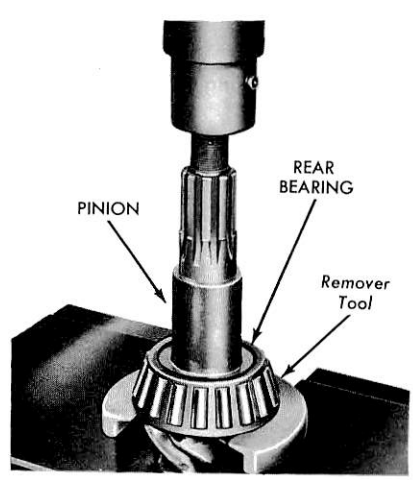
E1804-C

FIG. 5 Typical Single-Speed Single-Reduction Axle—Rockwell

12. On a Rockwell axle, install puller screws in the pinion bearing retainer. Tighten the screws evenly (3 to 5 turns each, one at a time) and pull the pinion and retainer assembly from the carrier housing. The use of a pinch bar will damage the shims. Driving the pinion from the inner end with a drift will damage the bearing locking groove.
13. With a micrometer, measure the shim or shims which were installed between the pinion bearing retainer and the carrier housing. Record this reading. No less than three shims are usually needed. Wire the shims together so they do not get misplaced, and to make assembly easier.
14. Press the pinion out of the front pinion bearing and bearing retainer. Press the rear bearing and spacer off the pinion shaft (Fig. 6).
15. With a micrometer, measure the pinion bearing spacer thickness.
16. On a Rockwell axle (Fig. 5) remove the snap ring that retains the pilot bearing on the pinion shaft. Press the pilot bearing off the shaft.
17. If the pinion bearing cups are to be replaced, press them out as shown in Fig. 7.
18. Clean and inspect the parts as given in Part 15-01.

Assembly

1. Press the pinion pilot bearing on the pinion shaft (with the large chamfer on the inner race toward the pinion teeth). On a Rockwell axle, install the pilot bearing retaining snap ring.
2. Press the pinion rear bearing on the shaft until seated against the back



E1807-A

FIG. 6 Removing Pinion Rear Bearing Cone

face of the pinion gear.

3. Press the pinion bearing cups in the bearing retainer (Fig. 8).
4. Install the pinion in the bearing retainer. Place the old spacer on the pinion shaft for a trial build-up. Install the pinion front bearing. Adjust and check the bearing preload as given in Part 15-01.
5. After the pinion bearing preload is adjusted, install a new oil seal.

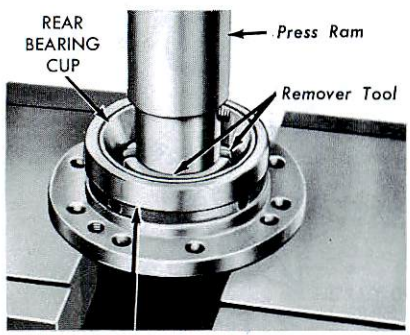


FIG. 7 Removing Pinion Bearing Cup

Install the gasket between the bearing retainer and the oil seal retainer. Install the universal joint flange.

6. If the pinion and ring gear set is being changed, adjust the shim thickness as given under Adjustments in Part 15-01.
7. Install the pinion and retainer assembly in the carrier housing using the correct shims. Install the capscrews, which attach the bearing retainer to the carrier housing. Torque the capscrews to specification.
8. If the ring gear is to be replaced, see Part 15-01 for the correct procedure.
9. Apply a coating of rear axle lubricant on the spider, pinions, side gears, and thrust washers, then assemble them in the ring gear half of the case. Align the punch marks and install the other half of the case. Install the retaining capscrews or the bolts and nuts, and torque to specification. Install the lock wire. Press the differential bearings on the case (Fig. 9).
10. Install the differential assembly and adjust the gear backlash and bearing preload as given in Part 15-01.
11. When the backlash and bearing preload are within limits (see Specifications) check the gear tooth contact pattern (Part 15-01).
12. Tighten the thrust block screw, if so equipped, until the thrust block touches the ring gear. Back off the screw at least 1/6 turn but not more than 1/4 turn to provide the proper (0.010-0.020) clearance between the block and the ring gear. Tighten the lock nut while holding the screw in this position.
13. Install the oil distributor, if so equipped.

DESCRIPTION

Eaton 2-speed and double-reduction rear axles are available on 500-9000 series trucks. These axles are also used as the rearward axles on Eaton tandem 2-speed and double-reduction units.

DIFFERENTIAL CARRIER

Two-speeds and double-reduction are obtained in these axles by a planetary gear set which operates between the differential ring gear and the differential case.

In the two-speed axles, the planet gear set can be shifted into low speed (reduction) or into high speed (direct) (Fig. 1).

In the double-reduction tandem axles, the planet gear set is permanently locked in the low-speed position (Fig. 1).

Figure 2 shows the power flow through the axle. In the low-speed or double-reduction position, the drive pinion drives the planetary ring gear (first reduction). The planetary ring gear drives the planetary ppinions which are mounted on the differential case. Since the planetary sun gear is locked to the carrier housing and cannot turn, the planetary pinions are forced to walk around the sun gear. This walking around causes the differential case to rotate slower than the ring gear (second reduction). The differential case and spider pinions drive the side gears in the conventional way.

In a 2-speed tandem, the shift from low-speed to high-speed is made by unlocking the planetary sun gear from the carrier housing and locking it to the differential case. This causes the planetary gear set to rotate as a unit so that the second reduction is eliminated.

In a typical two-speed axle in low-speed operation, the drive from the transmission is reduced in the ratio of 5.57:1 between the drive pinion and the differential ring gear. The drive at the differential ring gear is further reduced by the planetary gear set operating between the differential ring gear and the differential case, hence double reduction.

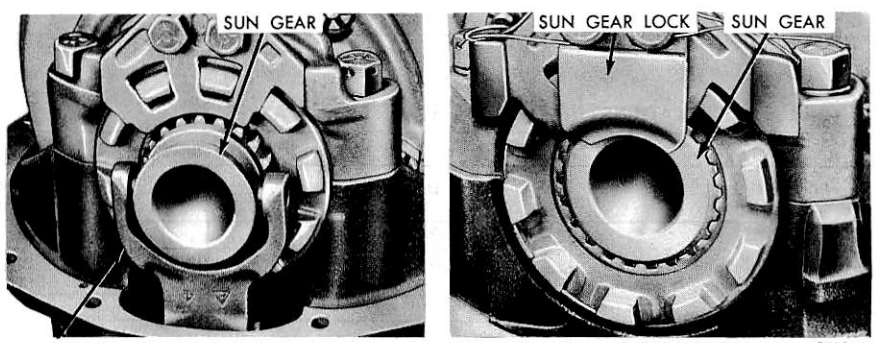

FIG. 1 Two-Speed and Double-Reduction Sun Gears

In high-speed operation, the planetary reduction is eliminated and the final axle drive ratio is now only that of the drive pinion and differential ring gear (5.57:1).

Axle Lube Filtering

An external filter with a reinforced paper element is used. Lubricant from the ring gear flows into the top of the filter, down through the element, and returns to the axle reservoir. Non-magnetic, as well as magnetic, particles are removed from the lubricant, promoting longer axle life. This by-pass filtering system does not affect Eaton axle forced-flow lubrication. Maintenance requires only the removal of one nut and the cover, to replace the element.

Also, a drain plug to which magnetic discs are attached is available. This provides an additional method of filtering metallic particles out of the axle lubricant.

ELECTRICAL SHIFT CONTROL

An electric shift control is used in conjunction with the two-speed axles.

The electric shift control system is composed of the control switch, the speedometer adapter, the axle shift unit, the circuit breaker, and the wiring harness.

The control switch, mounted on the gear shift lever (Fig. 3), has two positions-up for high axle range and down for low axle range. When the switch is in either of these positions, a slide-contact, attached to the control switch shaft, completes the circuit between the battery and the motor in the axle shift unit (Fig. 4).

The speedometer adapter is installed between the transmission and speedometer, and compensates for variations in the speed of the drive shaft between the high and low speed ranges of the axle. The adapter is held in the high range by a spring and in the low

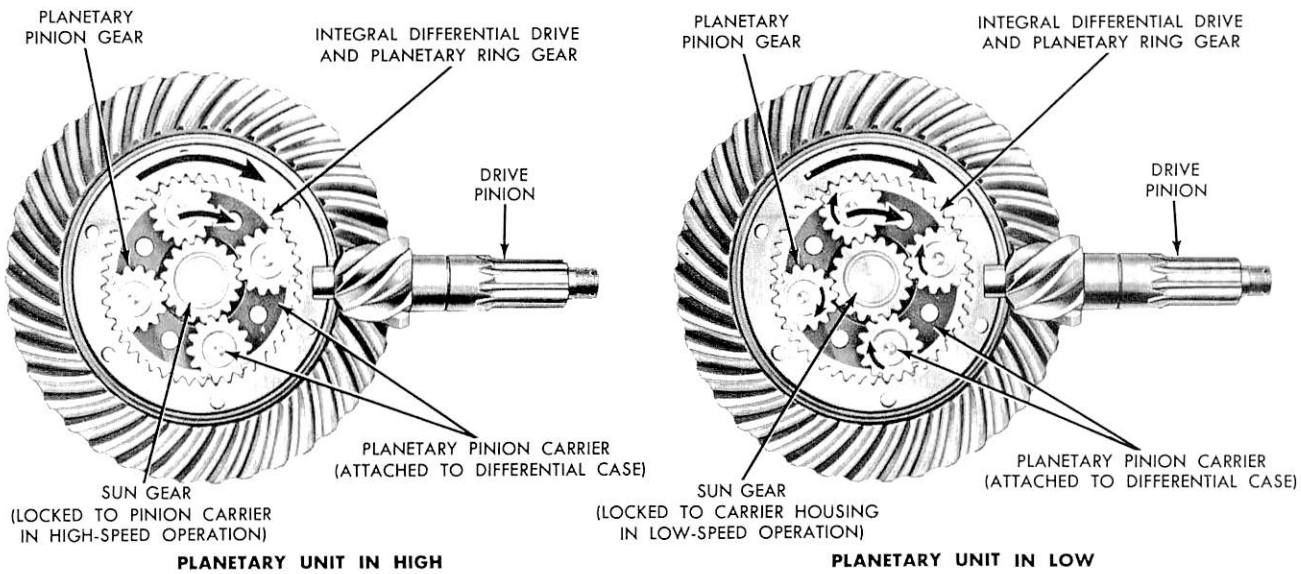

FIG. 2 Power Flow Planetary Two-Speed Axles

range by an electromagnet. The inner mechanism is prelubricated and sealed by the manufacturer. In the event of failure, the adapter is replaced as a unit.

The axle shift unit is mounted on the differential carrier. This unit contains a reversible electric motor which, when energized, shifts the axle into the desired range through the mechanism contained in the unit. The position of the mechanism in both axle ranges is shown in Fig. 5.

A circuit breaker protects the system against a short circuit. Should a short circuit occur, the breaker will intermittently de-energize the entire system until the trouble has been corrected.

High Speed Range

When the control button is placed in the up position, current is supplied to one field of the motor in the axle shift unit. This current turns the armature and the drive screw in a clockwise direction and moves the nut toward the bottom of the screw (Fig. 5).

When the nut has traveled far enough to wind the spring, a contact bumper on the nut breaks an electrical connection on the automatic switch, which de-energizes the motor and stops armature rotation. The nut is held at the end of its travel by a ball screw detent spring mounted on the front cover.

As the nut moves downward, the spring winding lever, which pivots on a

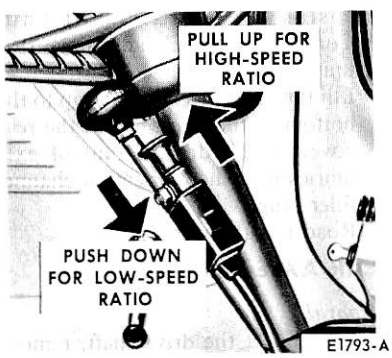

FIG. 3 Control Switch Gear Shift Lever

pin in the nut, winds the torsion spring. Thus the tension of the spring is increased, and in this position, the axle is ready to shift into the high speed ratio as soon as the load on the axle gear is relieved.

The torsion spring is assembled in the unit so that it is under 50 to 80 pounds pressure. When the spring is wound by the winding lever, this tension is increased to 90 to 150 pounds. This additional pressure is used to shift the axle. When the shift is completed, the ends of the spring come together, leaving the original tension in the spring. This preload tension holds the axle in either range.

Low Speed Range

When the button is placed in the down position, current is supplied to the

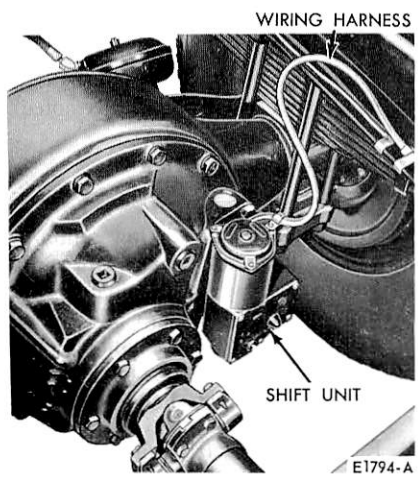

FIG. 4 Typical Axle Shift Unit Installation

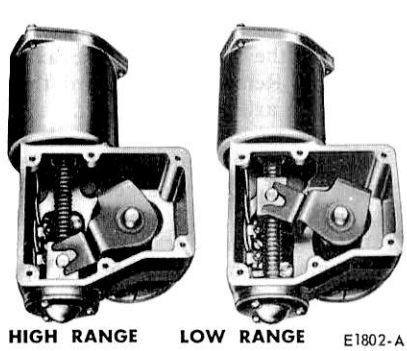

FIG. 5 Axle Shift Control Positions

other field of the motor and to the speedometer adapter. The current now causes the armature and screw to turn counterclockwise, and the nut travels toward the top of the screw (Fig. 5). This winds the torsion spring, for a shift to low range which is accomplished in the same manner as the shift to high range.

ADJUSTMENTS

Axle shafts, wheel hubs, wheel hub bearings, wheel hub grease seals, the electric shift unit, and the differential drive pinion oil seal can be replaced without removing the differential carrier assembly from the axle housing or the rear axle assembly from the vehicle.

The axle shafts, wheel hub, bearings, and grease seals may be replaced, lubricated, or adjusted as detailed under Adjustments in Part 15-01.

The drive pinion oil seal may be replaced as detailed in Part 15-15 under Adjustments.

The electric shift unit can be replaced or overhauled as described in the following sections.

REMOVAL AND INSTALLATION

The Eaton two-speed rear axle and the Eaton planetary double-reduction rear axle are of the same basic design and operation. The following procedures for Removal and Installation will apply to both axle designs except where specifically noted.

DIFFERENTIAL CARRIER

Removal

1. Shift the axle into the low ratio.
2. Drain and discard the axle lubricant.
3. Remove the axle shaft, stud nuts and lock washers. Strike the center of the axle shaft flange with a hammer and drift to loosen the tapered dowels. Remove the axle shafts from the housing.
4. Remove the electric shift unit from the carrier housing. Disconnect the drive shaft at the rear universal joint flange.
5. Support the carrier on a roller jack. Remove the carrier to housing bolts and lock washers (or stud nuts).
6. Remove the carrier from the axle housing. Remove and discard the carrier to axle housing gasket.

Installation

1. Install guide studs in the axle housing. Place a new gasket over the guide studs.
2. Install the carrier in the axle housing. As the carrier to housing bolts are installed, remove the guide studs. Torque the bolts (or nuts) to specifications.
3. Install the axle shafts through the housing ends so that they will spline to the differential side gears. Install the tapered dowels, lock washers, and axle shaft flange stud nuts.
4. Install the electric shift unit. Connect the drive shaft at the rear universal joint flange.
5. Fill the axle with lubricant up to the bottom of the filler hole in the rear cover, then add one pint of axle lubricant at the lubrication channel filler plug.
6. Road test the vehicle.

REAR AXLE HOUSING

Removal

1. Disconnect the drive shaft, remove the axle shafts, and remove the differential carrier as outlined in the foregoing procedure.
2. Disconnect the rear shock absorbers from the shock absorber lower attaching brackets, if so equipped. Then raise the rear end of the vehicle frame until the weight is off the rear springs. Place safety stands under the frame in this position.
3. Disconnect the flexible hydraulic hose on air line at the frame.
4. Remove the nuts from the spring clips (U-bolts), and remove the spring seats and lower shock absorber attaching brackets.
5. Roll the axle from under the vehicle. Remove the wheels.

Installation

1. After installing the rear wheels, roll the axle assembly under the vehicle.
2. Install the spring clips (U-bolts), spring seats, and shock absorber lower brackets and torque to specifications shown in Group 14-31.
3. Connect the rear shock absorbers. Lower the vehicle to the floor.
4. Connect the air line or hydraulic brake hose and bleed the brakes.
5. Install the differential carrier and axle shafts, and connect the drive shaft as outlined under Installation in the foregoing procedure.

ELECTRIC SHIFT UNIT

Removal

1. Disconnect the two wires which lead to the axle shift unit. Quick disconnects will be found between the second (from the rear) and third harness retainer clips on the left frame rail.
2. Remove the two shift unit housing to carrier stud nuts and lock washers, and remove the unit from the carrier (Fig. 4).

Installation

1. Position the lead wires on the housing terminals. **The red wire must be installed on the lower terminal. After wiring corrections have been made, cover the entire area of terminals and wire connectors with plastic resin sealer (C3AZ-19560-A), to prevent corrosion damage to terminal connections. Sealer should be firmly pressed in place by hand.**
2. Position the shift unit on the differential carrier studs with the torsion spring swivel block installed in the shift fork slot, then install the lock washers and stud nuts.
3. Tighten the stud nuts to specifications. Fill the shift unit, to

the level of the filler plug, with the correct lubricant.

4. Connect the motor wire at the quick disconnects, and install the harness clips on the frame rail.

DISASSEMBLY AND ASSEMBLY

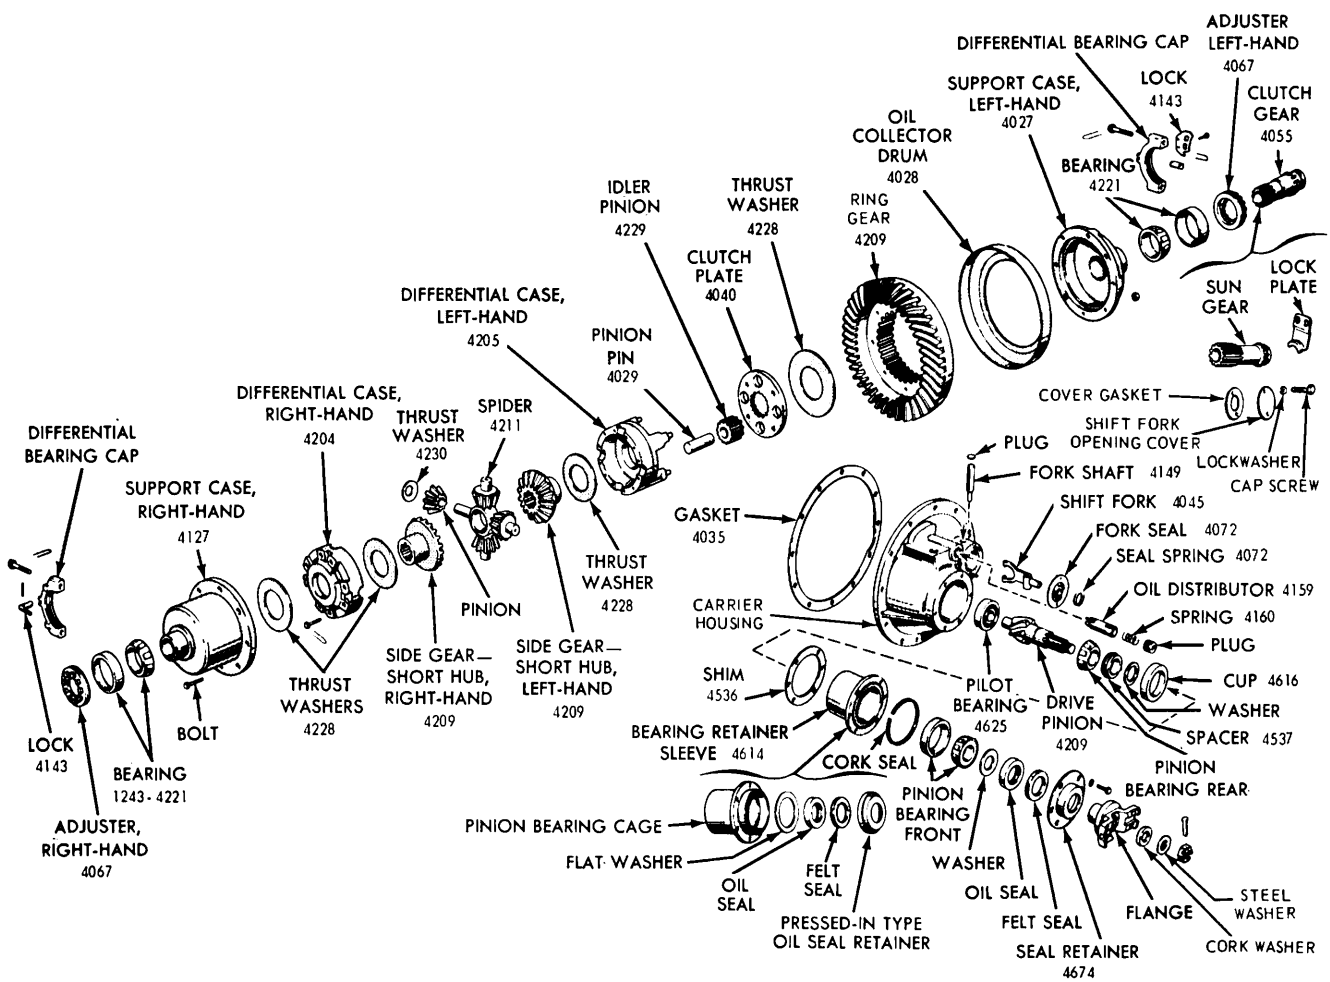
DIFFERENTIAL CARRIER

Disassembly

1. Inspect the carrier before disassembly as given in Part 15-01.
2. After removing the oil distributor plug if so equipped, (Fig. 6), pull the oil distributor and spring out of the differential carrier.
3. Remove the shift fork shaft plugs, and remove the shaft.
4. Remove the shift fork seal and the shift fork from the housing. Pull the sliding clutch gear out of the differential carrier (Fig. 7).
5. Mark the right and left bearing adjusters with a punch to aid in relocating the adjustment when reassembling. Remove the lock wires from the differential bearing cap bolts, and remove the bolts.

Back off one bearing adjusting nut to relieve the bearing preload.

6. Remove the right and left bearing caps, bearing adjusters, and locks.
7. Lift the differential and planetary assembly out of the differential side



E 1801-C

FIG. 6 Eaton planetary Two-Speed or Double-Reduction Axle

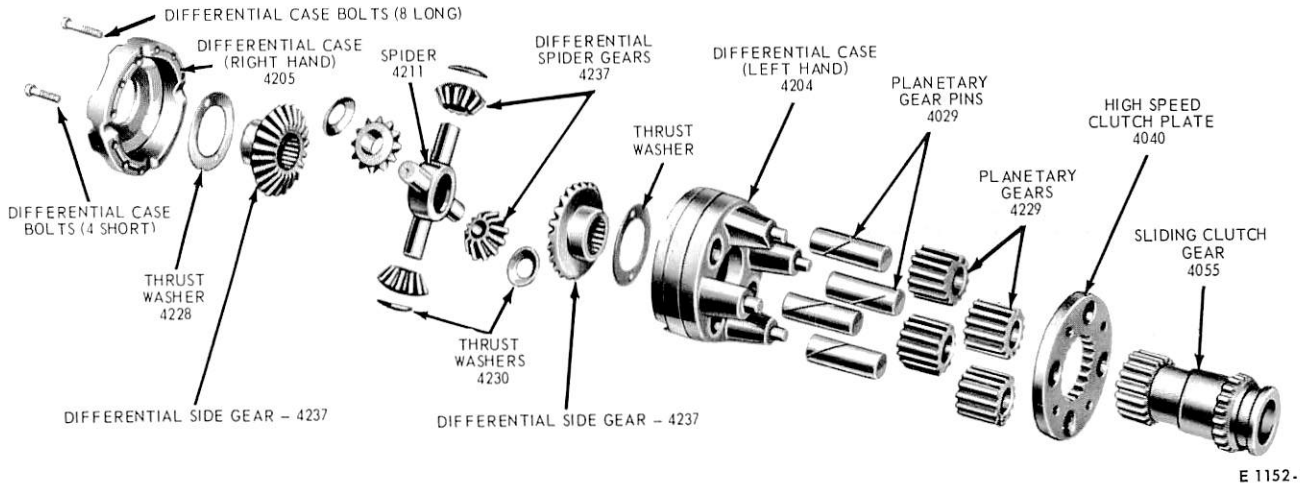


FIG. 7 Planetary and Differential Assembly

bearing cups.

8. Mark the right and left support cases so that they can be reassembled in the same relative position. Remove the lock wire and nuts from the bolts which hold the ring gear to the gear support cases. Remove the bolts.
9. Clamp the differential assembly in a soft-jaw vise with the ring gear end up.
10. Tap the ring gear with a soft hammer on the gear tooth side until the gear is free of the flange on the right support case (Fig. 6).
11. Lift the left support case, thrust washer, oil collector drum (if so equipped) and ring gear from the right support case.
12. Remove the high-speed clutch plate from the differential case by tapping on each side alternately with a soft hammer.
13. Remove the planetary gears and planetary gear pins.
14. **Lift the differential assembly out of the right support case. Remove the thrust washer from the support case. Mark the two pieces of the differential case for proper assembly.**
15. Remove the lock wire and capscrews from the differential assembly, and separate the right and left differential cases. Remove the differential side gears and thrust washers.
16. Remove the differential spider gears, thrust washers, and the differential spider (Fig. 7).
17. If the differential support case bearings are to be replaced, they may be removed with a drift (Fig. 8). Press on the new bearings so that the ram pressure is against the bearing inner race and not against the roller cage (Fig. 8).

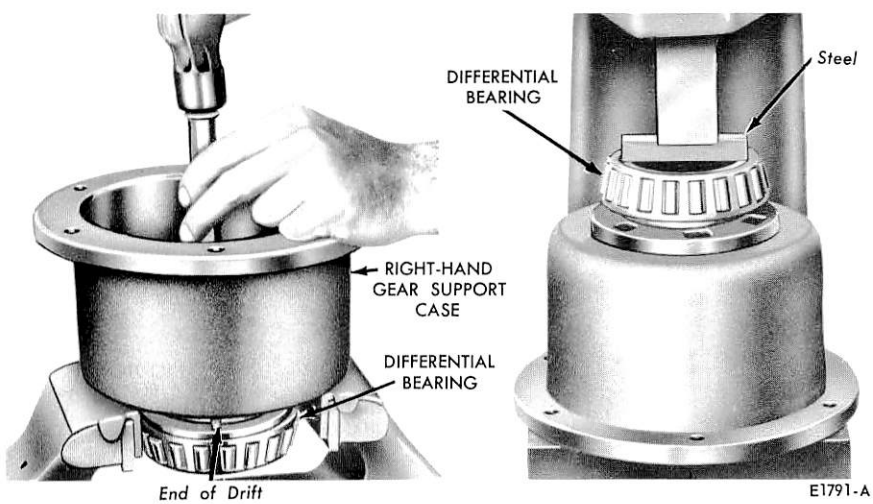

FIG. 8 Removing or Installing Differential Bearing

18. Hold the pinion shaft flange and remove the pinion shaft nut.
19. Remove the bolts that attach the pinion bearing sleeve to the carrier housing. With a drift, drive the pinion assembly out of the front of the carrier housing.
20. **Place the pinion assembly on a press bed and press the pinion shaft out of the pinion shaft flange and pinion shaft front bearing cone. Remove the bearing preload spacer from the pinion shaft.**
21. If the pinion rear bearing cone is to be replaced, remove the pilot bearing with the type of tool shown in Fig. 9. Then, remove the pinion rear bearing cone with the type of tool shown in Fig. 10.
22. If the pinion bearing cups are to be replaced they may be removed with a steel bar as shown in Fig. 11.
23. Inspect the parts as given in Part 15-01.

Assembly

1. Press the pilot bearing on the pinion shaft and stake the pinion shaft end at 4 points.
2. Press the pinion rear bearing onto the pinion shaft until seated.
3. To install a new bearing cup, place the pinion bearing retainer sleeve in a press and, using a steel bar, press the cup in the sleeve until it is seated against the recess in the sleeve (Fig. 11). Repeat this operation for the other cup.
4. Install the pinion in the bearing retainer sleeve. Place the old spacer on the pinion shaft for a trial build up. Install the spacer washer and the pinion front bearing.
5. Check and adjust the pinion bearing preload as given in Part 15-01.
6. Install a new oil seal in the seal retainer or bearing sleeve.
7. Press the universal joint flange on the pinion shaft. Install the flat

washer and nut. Tighten the nut to specifications.

8. If the pinion and ring gear are being replaced, adjust the shim pack between the pinion bearing sleeve and carrier housing as given in Part 15-01.
9. Install a new gasket in the pinion bearing sleeve, if so equipped.
10. Place the shim pack on the bearing sleeve and install the pinion and sleeve assembly in the carrier housing. Install the sleeve to housing bolts and lock washers. Tighten to specified torque.
11. Place the left half of the differential support case (Fig. 7) in a vise with the planetary side facing downward. Place one of the differential side gear thrust washers in position in the case. Place the differential left-hand side gear (with the short hub) in position in the case.

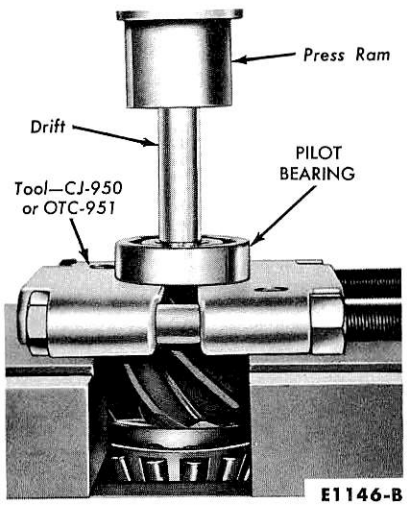

FIG. 9 Removing Pinion Pilot Bearing

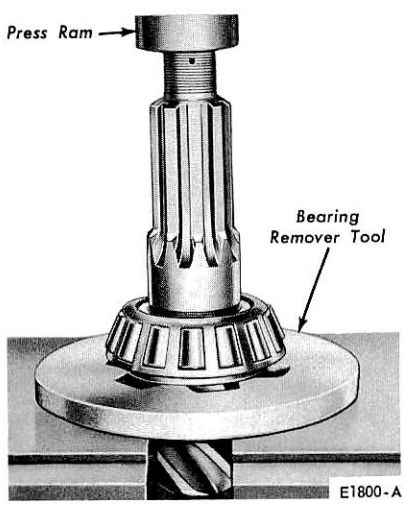

FIG. 10 Removing Pinion Rear Bearing Cone

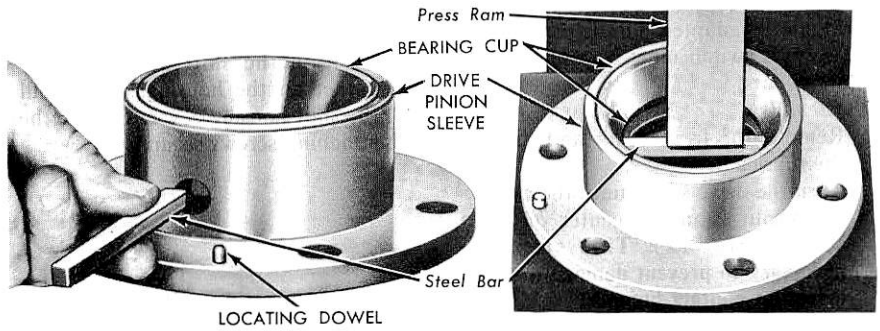

FIG. 11 Removing or Installing Pinion Bearing Cup

12. Install the four differential pinions and thrust washers on the differential spider, then place the spider in the differential case.

Place the right side gear and thrust washer on the differential pinions.

13. Place the right half of the differential case in position over the differential spider, then install the differential case bolts. Tighten them to the specified torque.
14. Place the differential assembly on the bench, and insert the four planetary gear pins in the holes in the differential case (Fig. 7).
15. Place the four planetary gears in position on the planetary gear pins. Position the high speed clutch plate on the planetary gear pins with the chamfered teeth facing the planetary gears. Tap the plate in place with a brass hammer.
16. Place the right gear support case in a vise with the bearing side facing downward. Position the gear support thrust washer in the case.
17. Place the differential assembly in the gear support case with the planetary end facing upward. Place the ring gear over the differential assembly, with the teeth on the ring gear facing downward, and mesh the planetary gears with the internal teeth on the ring gear.
18. Line up the bolt holes in the ring gear with the bolt holes in the gear support case. Place the oil collector drum (if so equipped) on the ring gear with the open side facing the gear. Prior to installing collector drum (ribbed type carriers only) bend tangs slightly to provide tension between drum and support case. Place the notches in the oil collector drum between the bolt holes in the ring gear.
19. Apply oil to each side of the high-speed clutch plate thrust washer, then position the washer on the high-speed clutch plate. Place the left gear support case on the ring gear, and line up the bolt holes in the ring gear and both gear support cases.

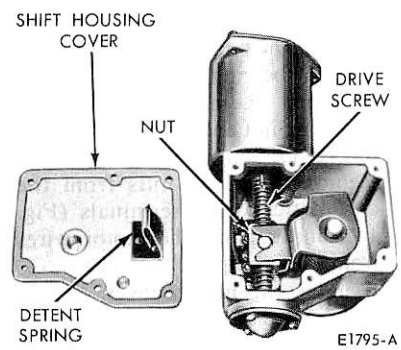

FIG. 12 Drive Screw Nut in Center Position

20. Install the bolts through the gear support cases with the bolt heads against the flange of the right gear support case. Install the nuts on the bolts, and tighten to specifications.
21. Install the differential assembly in the carrier housing and adjust backlash and preload as given in Part 15-01.
22. Check and adjust the gear tooth contact pattern as given in Part 15-01.
23. Install the sliding clutch gear, then position the shift fork on the sliding clutch gear. Install the shift fork shaft through the hole in the differential carrier and into the shift fork. Install the shift fork shaft plugs. Place the shift fork seal and retainer on the shift fork. Shift the axle into the low range.
24. Place the oil distributor and spring in position in the differential carrier. Install the oil distributor plug and gasket, if so equipped.

ELECTRIC SHIFT UNIT

The rear axle shift unit is the only part in the control system which can be

disassembled for repairs. The speedometer adapter, circuit breaker, and control switch must be replaced if failure occurs.

Disassembly

1. Remove the front cover and drain the lubricant.
2. Turn the drive screw until the drive screw nut is in the center of the screw (Fig. 12). **This step is necessary to prevent damage to the drive nut contact bumper.**
3. Pull the shaft out of the torsion spring assembly, then remove the assembly from the housing.
4. Remove the screws and lock washers which attach the drive screw bearing cover to the housing, and remove the cover and gasket.
5. Push down on the screw assembly until the bearing is forced out of the housing. Remove the bearing attaching nut and bearing as shown in Fig. 13.
6. Remove the lock nuts from the automatic switch terminals (Fig. 14), and remove the motor wires from the terminals.
7. Remove the motor cover screws, and remove the motor and the cover gasket from the housing.
8. Remove the jam nuts and fiber washers from the terminals at the rear of the housing. Remove the automatic switch center screw, and lift the switch out of the housing.
9. Mount the torsion spring and lever assembly in a vise as shown in Fig. 15. Turn the spring-winding lever clockwise, and pull outward to disengage the spring from the lever. Reverse this procedure to assemble the spring (Fig. 16).

Assembly

1. Position the automatic switch in the housing, and install the switch attaching screw. Install the fiber washers and jam nuts on the switch terminals at the rear of the housing.
2. Place the motor cover gasket on the housing, and install the motor and cover in the housing. Install the motor cover screws. Position the motor wires on the automatic switch terminals, and install the lock nuts.
3. Place the drive screw assembly in the housing, and install the drive screw bearing and the bearing retainer nut on the drive screw (Fig. 13). Tap the bearing into the bearing seat in the housing. Install the bearing cover gasket and cover on the housing.
4. Center the drive screw nut on the drive screw, making sure the contact bumper on the nut is toward the automatic switch.
5. Position the torsion spring assembly in the housing, then install the shaft.
6. Position the shift housing cover gasket on the housing, and install the shift housing cover. Tighten the attaching screws securely.

DESCRIPTION

DANA DESIGN FRONT FOUR-WHEEL DRIVE AXLE

A unique front wheel drive axle is provided on the Bronco vehicle. An open yoke is welded to the outer ends of the axle housing. This construction makes for a very strong spindle area. Power to drive the front wheels is transmitted through open Cardan-type universal joints. Ball and socket joints are now used. A new spindle bore seal is used. The seal is installed on the axle shaft rather than being retained in the spindle. Due to its' special design, the seal acts as a slinger as well as a seal (see Figs. 1 and 4).

The differential section of the Dana Model 441F axle is similar in design (but not in size) to the other Dana units used on Ford vehicles (Fig. 2). The differential carrier is integral with the axle housing. Adjustment of the side carrier bearings is accomplished by means of shims placed between the bearings and the differential case. The carrier side bearings are pre-loaded by the squeezing action of the housing. A spreader must be used (Fig. 12) on the axle housing to relieve the tension on the differential bearings and permit removal or installation of the differential. Pinion depth is controlled by a shim pack located to the rear of the pinion bearing. Pinion bearing preload is controlled by variable-size spacers. Where necessary, special service tools have been designed and are available to service the Dana axle used in the Bronco.

The front axle is of the integral carrier-housing, hypoid gear type, in which the centerline of the drive pinion is mounted below the centerline of the ring gear.

The integral pinion gear and shaft is supported by two opposed tapered roller bearings which are assembled in the forward side of the carrier housing. Pinion locating shims, installed between the rear bearing cup and the cup seat, control the drive pinion depth adjustment. The pinion bearing preload is controlled by shims located between the pinion front bearing and the shoulder on the drive pinion shaft.

The differential case assembly is supported by two opposed tapered roller (side) bearings and cups, which are retained in the housing by removable caps. Shims, installed between each differential side bearing and the shoulder on the case, perform three functions: they take up the differential case side clearance: they adjust the backlash between ring gear and pinion: and they establish differential side bearing preload.

A cover on the front of the carrier housing provides access for inspection, removal and installation of the differential assembly and drive pinion. A metal tag, stamped with the gear ratio plus the number of teeth on the ring gear and pinion, is secured to the housing by one of the cover bolts.

Vehicles equipped with limited-slip differential assemblies will have an additional metal tag identification attached to one of the cover bolts.

FRONT WHEEL DRIVE HUB-LOK HUB

The free-running hub is standard equipment for the Dana front axle of the Bronco. It is the internal locking type.

OPERATION

Lock Position

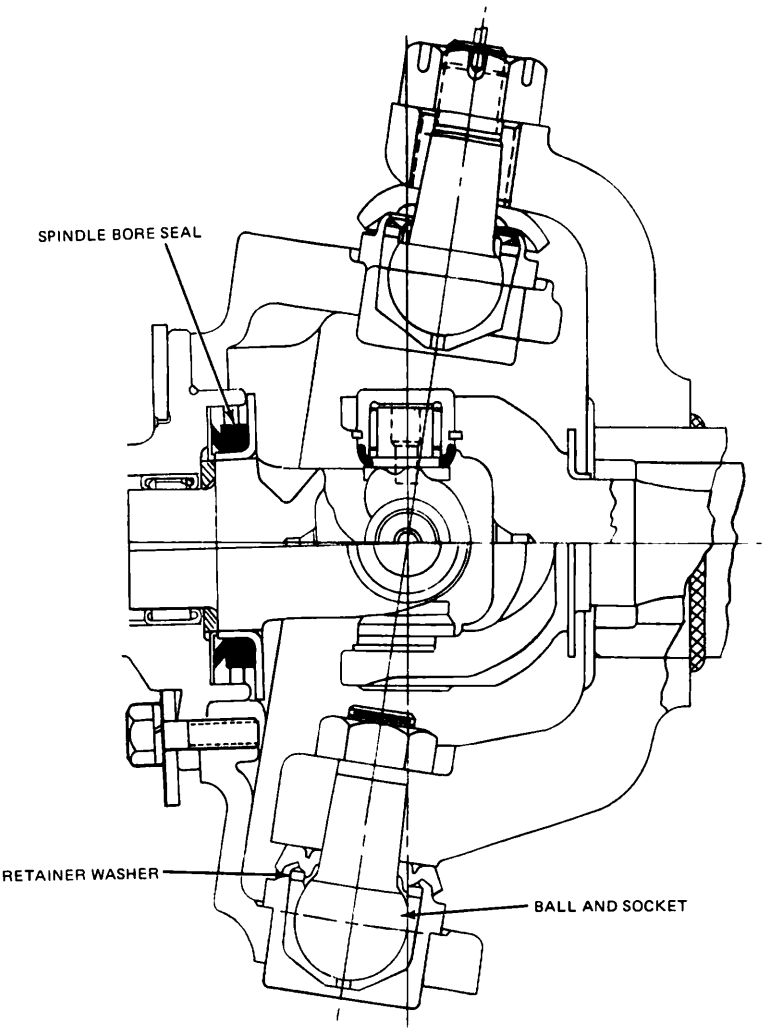
When the transfer case is to be shifted into the position for driving the front axle, the hub lock pointer on the center bar must point to the notch under

the word LOCK on the retaining plate. If the clutch teeth do not engage with the knob turned to this position, the clutch teeth are butted and a slight movement of the wheel in either direction will complete the lock. The front axle will now drive the wheel. Do not operate in four-wheel drive with the hubs disengaged.

Free Running Position

When the transfer case is to be shifted into the position for driving the rear axle only, turn the hub lock pointer on the center bar so it points to the notch under the word FREE on the retaining plate. This will disengage the clutch teeth and thus unlock the wheel hub from the axle shaft. The wheel will now turn free on the axle.

Be certain that the transfer case is shifted into 2-wheel drive position before disengaging the hub lock.



E2259-C

FIG. 1 Ball Joint and Seal Assemblies

REMOVAL AND INSTALLATION

FRONT AXLE SHAFT AND STEERING KNUCKLE

Removal

1. Raise the vehicle on a hoist.
2. Remove the front wheel free running hub; then remove the front wheel hub and drum as an assembly. Refer to Group 11 Part 12, for procedures.
3. Remove the capscrews that attach the brake backing plate and the spindle to the steering knuckle (housing). Remove the brake backing plate and secure it to one side to avoid damaging the brake hose. Carefully remove the spindle.
4. **Pull the axle shaft assembly from the axle housing, working the universal joint through the bore of the steering knuckle (Fig. 3). Use care to prevent damage to the seal. If it is bumped against the knuckle bore it can be damaged.** (At this point, the following parts can be replaced without further disassembly of the axle: axle shaft; universal joint; spindle bore seal and deflector, and spindle bore needle bearing.
5. To remove the steering knucle (housing), disconnect the steering connecting rod end from the steering knuckle.

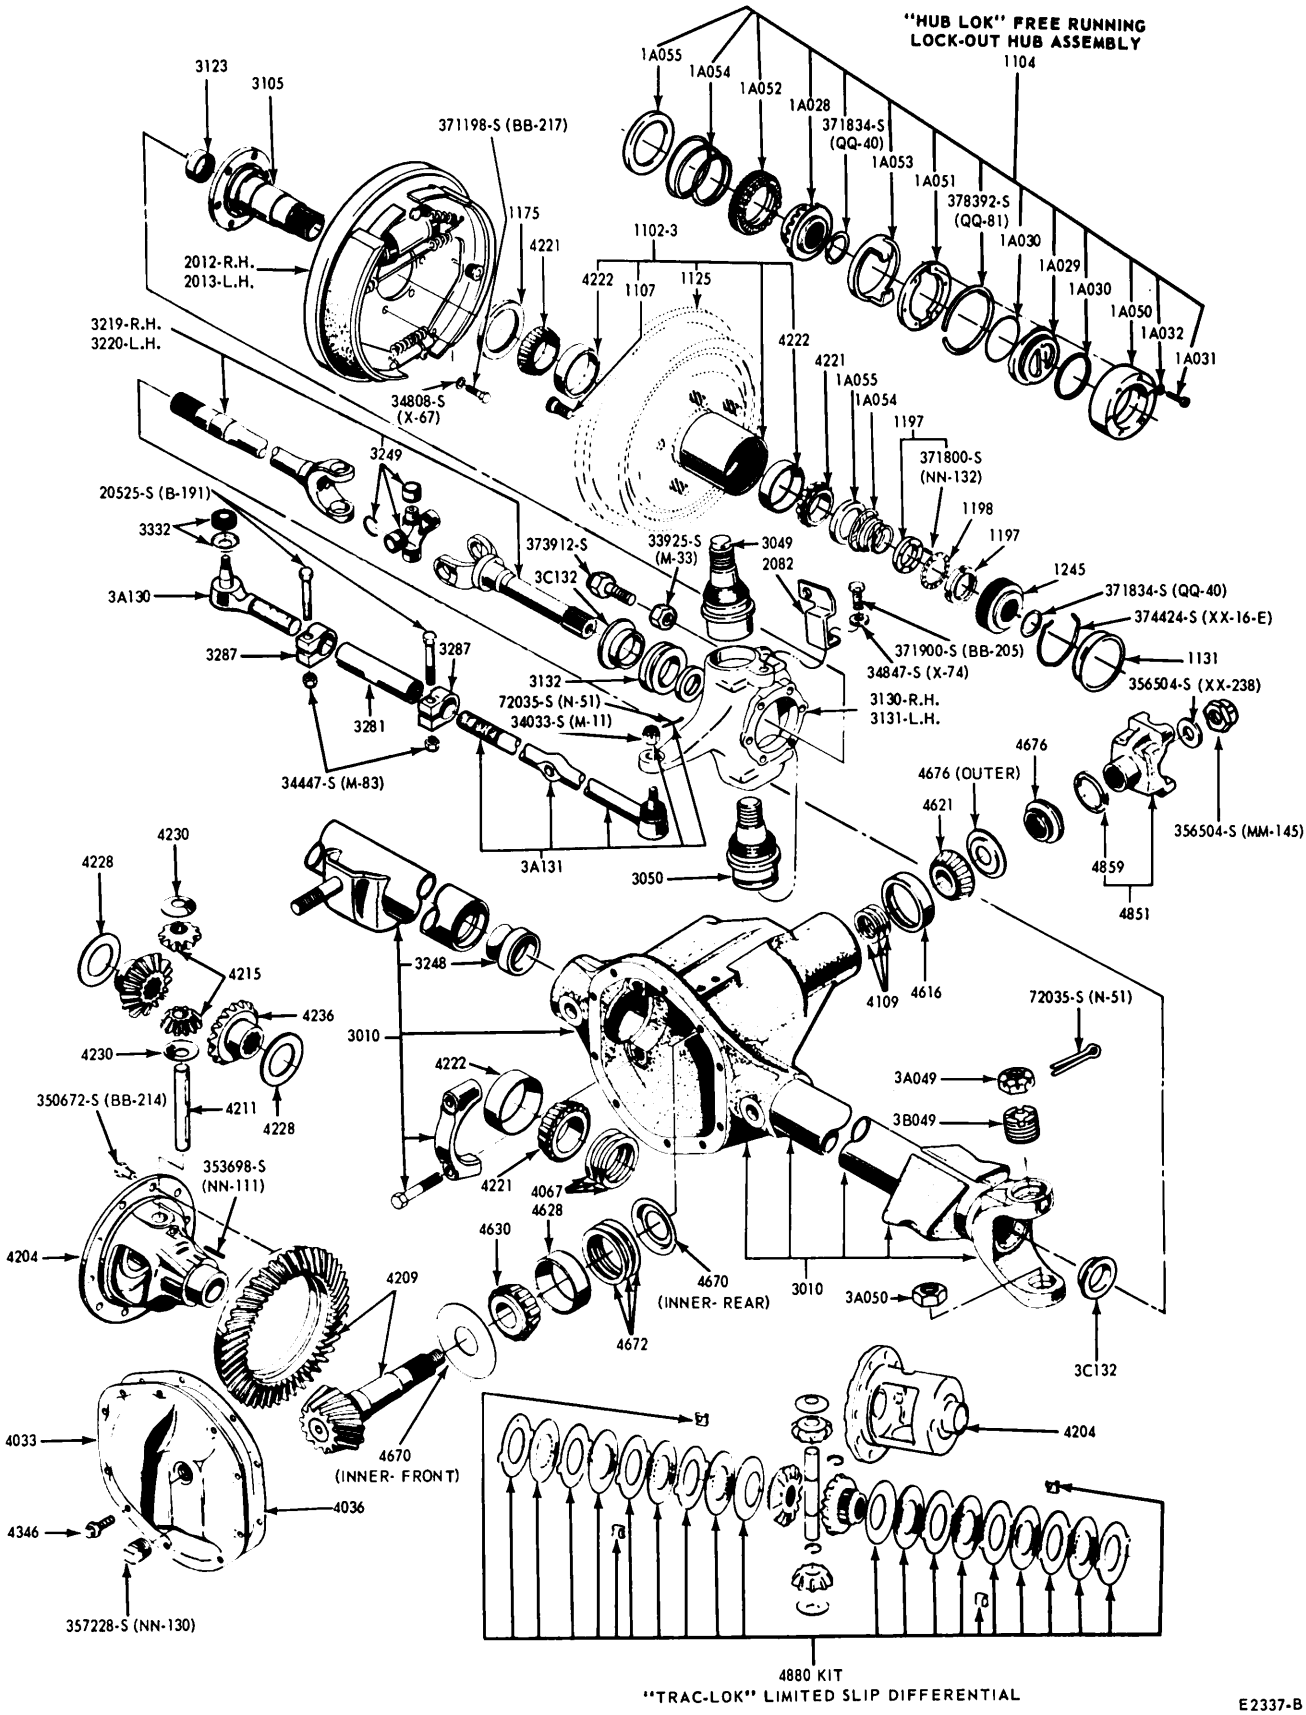


FIG. 2 Front Axle Assembly Complete Exploded View

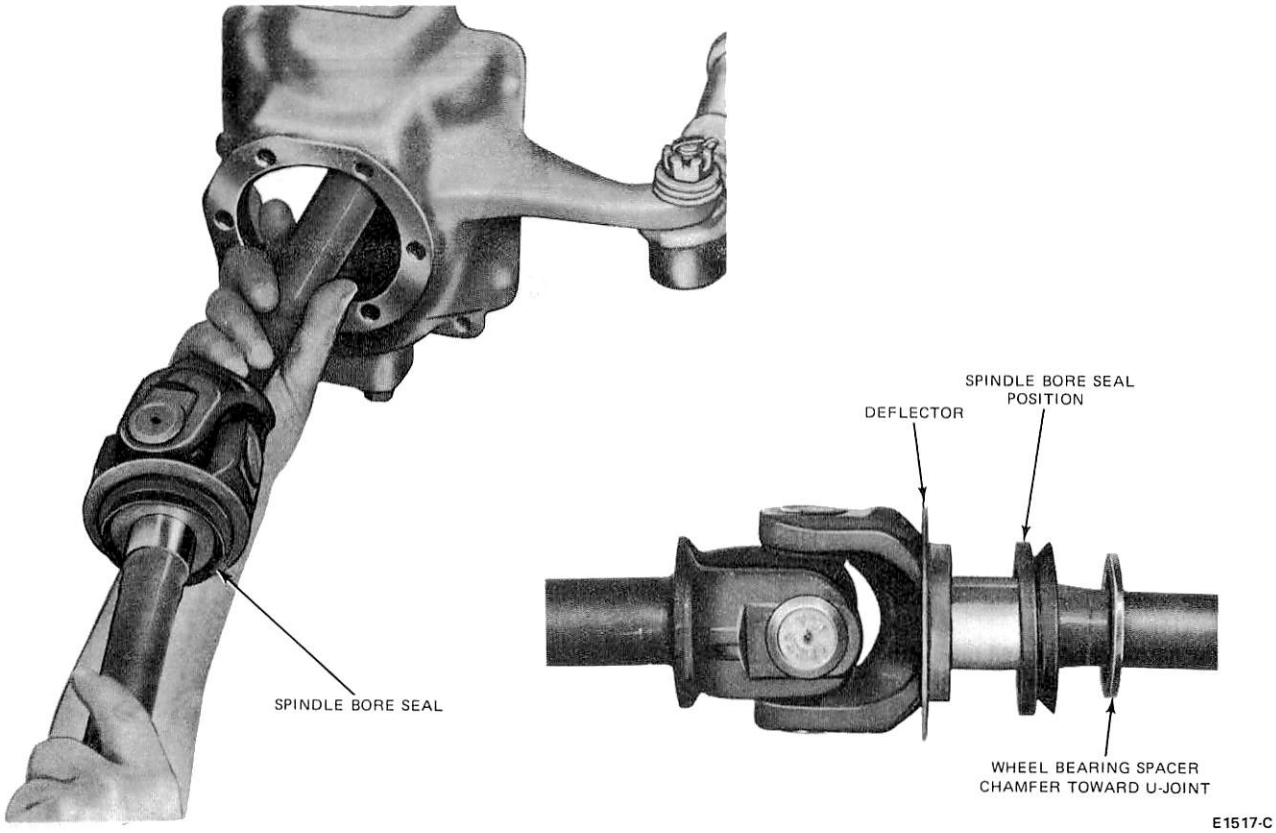

FIG. 3 Removing or Installing Axle Shaft—Typical

6. Remove cotter key from upper ball socket. Loosen the nuts from upper and lower ball sockets (Fig. 4). Discard nut from bottom socket after the knuckle breaks loose from the yoke. This nut is of the torque prevailing design and is not to be reused.
7. Remove knuckle from yoke. Assemble holding plate Tool 41395 and puller Tool 34123 with step nut Tool 27665 as shown. Tighten forcing screw to remove knuckle (Fig. 5).

In the event that the top socket should remain in the yoke, remove by hitting on top of the stud with a rawhide hammer. Discard the socket and remove and discard the adjusting sleeve.

8. Remove bottom socket by removing clamps and puller jaws from the T of the puller Tool 34123 using only the T forcing screw and step plate. Torque forcing screw to push out bottom socket. Discard socket.

Remove adjusting sleeve and discard. Use tool, spanner wrench T71T-3010-G.

9. If the top socket did not remain in the yoke, remove it from the knuckle (Fig. 6).

Installation

1. Place knuckle in vise and assemble bottom socket. Place new socket into knuckle making sure it is not cocked; place the driver over the socket; place forcing screw into driver as shown. Apply torque to screw and force socket into knuckle (Fig. 7).
2. Make sure socket shoulder is seated against knuckle. Use a .0015 feeler gauge between socket and knuckle. Feeler gauge is not to enter at minimum area of contact.
3. Assemble top socket into knuckle. Assemble holding plate onto backing plate screw. Tighten nuts snug. Place new socket into knuckle. Be sure socket is straight and not in a cocked position. Place driver over

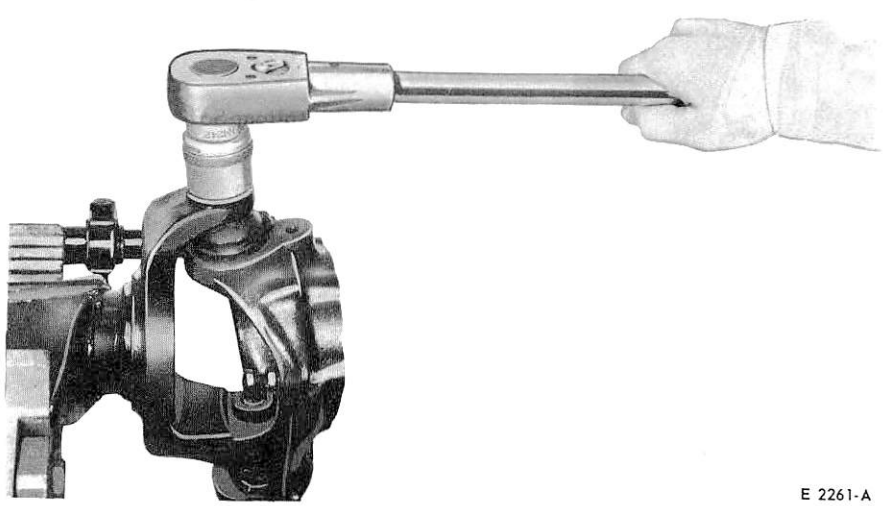

FIG. 4 Nut Removal

socket. Assemble puller tool exactly as shown (Fig. 8).

4. Make sure socket shoulder is seated against knuckle. Use a .0015 feeler gauge between socket and knuckle. Feeler gauge is not to enter at minimum area of contact.
5. Assemble new adjusting sleeve into top of yoke. Leave approximately two threads exposed. This will protect the threads in the yoke.
6. Assemble knuckle with sockets to yoke. Assemble new nut to bottom socket. Tighten nut finger loose. This will serve as a holding device.
7. **Place spanner wrench and step plate over adjusting sleeve. Locate puller exactly as shown, and turn forcing screw. This will pull the knuckle assembly into the yoke. With torque still applied, tighten the bottom nut on the socket. Torque nut to 70-90 ft-lbs (Fig. 9).**

If the bottom stud should turn with the nut, add more torque to the puller forcing screw since this will eliminate the turning of the stud because it should now be seated into the tapered hole of the yoke. Remove puller, step plate and holding plate.

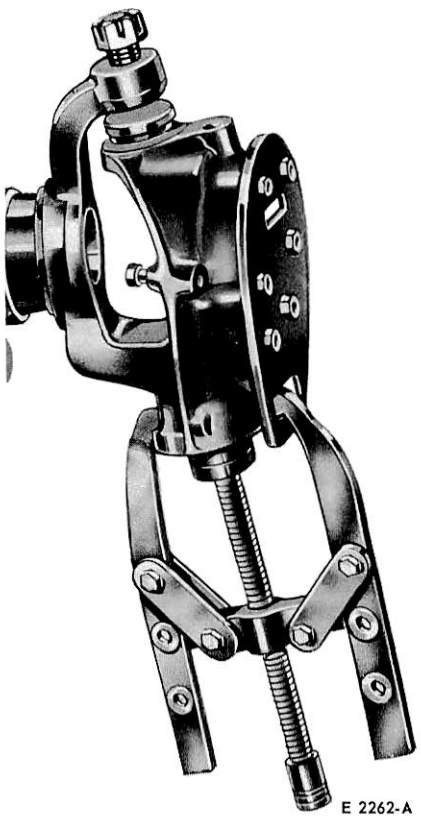

FIG. 5 Knuckle Removal

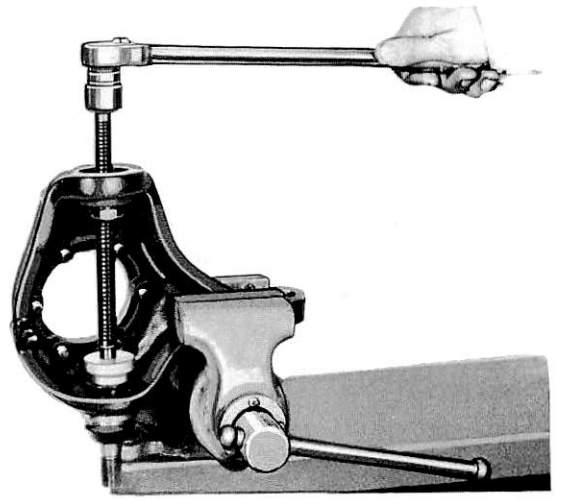

FIG. 6 Top Socket Removal

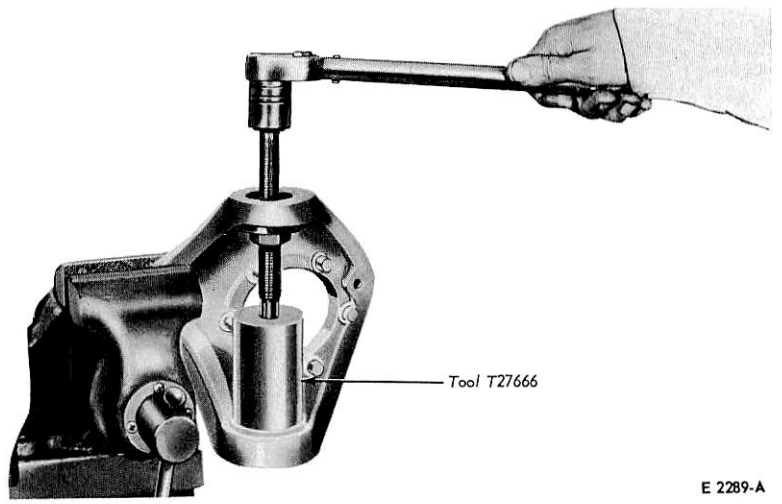

FIG. 7 Bottom Socket Installation

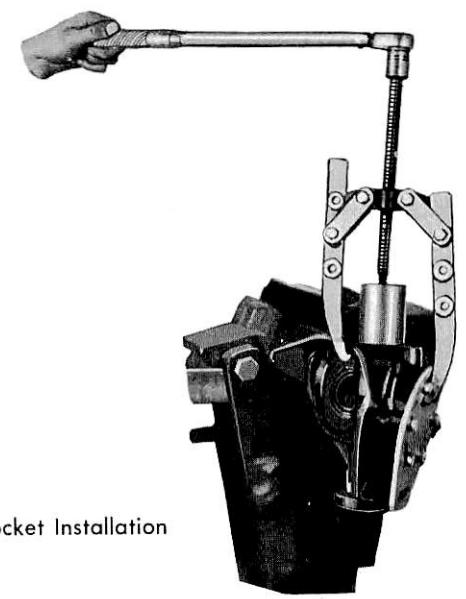

FIG. 8 Top Socket Installation

8. Torque adjusting sleeve to 40 ft-lbs using Tool T-27664. Remove spanner wrench.
9. Assemble top socket nut. Torque to 90 ft-lbs. Line up cotter key hole of stud with the castellation or slot of the nut. Tighten nut when it is being lined up with the hole of the stud. **Do not loosen nut.** Assemble a new cotter key. Before connecting the steering rod (tie rod) to the knuckle, the turning effort should be tested. The spring scale pull at the tie rod hole should not exceed 40 pounds. If the spring scale pull exceeds 40 pounds the ball joints should be replaced.
10. Connect the steering rod to the steering knuckle. Torque to specifications. After connecting the steering rod to the knuckle the turning effort should again be tested. For this test, the turning effort should not exceed 90 pounds.

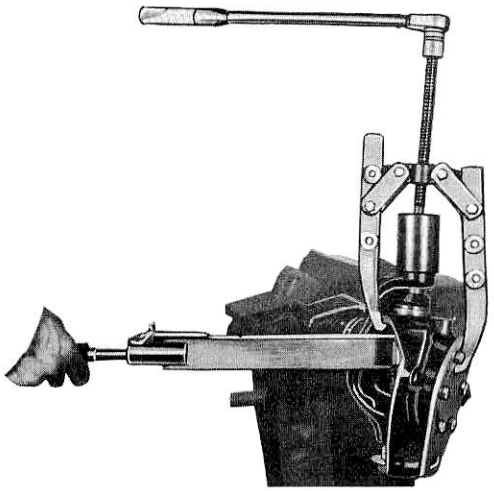
If it now exceeds 90 pounds, disconnect the steering rod and check both knucles separately to decide which is causing the excess turning effort. If both knuckles now check 40 pounds or less, the excess turning effort is in the tie rod or drag link. Take corrective action; then proceed with the next step.

11. **Make sure seal and deflector are properly installed on the axle shaft assembly (see inset on Fig. 3 for assembly sequence, and position of parts). Assemble seal on shoulder of deflector. Position wheel bearing spacer, and apply a small amount of lubricant C1AZ-19590-B to the exposed face of the spacer; then slide the axle shaft back into the housing using care not to damage the seal.**
12. **Install the backing plate, lubricate the spindle using C1AZ-19590-B lubricant (See Fig. 10) and install the spindle and torque the retaining screws to 30-40 ft-lbs.**
13. **Install the wheel, hub and drum as an assembly. Then install the free running Hub-Lok hubs (refer to Group 11, Part 12).**
14. Fill the axle with the proper grade and quantity of lubricant, as required.

DRIVE PINION OIL SEAL

Removal

The drive pinion oil seal can be replaced without removing the axle assembly from the vehicle. Compounded or synthetic rubber seals do not require soaking. Apply a light coat of axle lubricant to the seal on the shaft contact area.



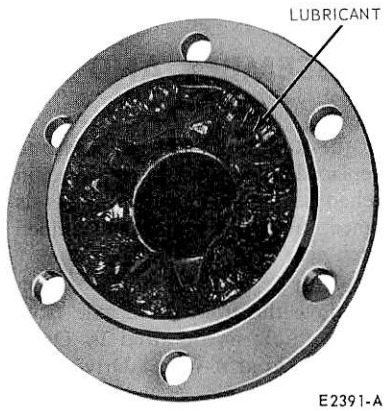
E 2290-A

FIG. 9 Assembly of Knuckle to Yoke

1. Raise the vehicle on a hoist or raise the front end of the vehicle with a jack. Install safety stands under the frame rails and lower the jack or hoist far enough to allow the axle to drop into the rebound position for working clearance.
2. Scribe marks on the companion flanges and U-joints for correct positioning at assembly, and remove the drive shaft.
3. Using Tool-4851-K to hold the pinion companion flange, remove the pinion shaft nut.
4. **Using Tool T53T-4851-A remove the companion flange.**
5. Using Tool-1175-AB, puller, in combination with slide hammer T50T-100-A, remove the pinion oil seal.

Installation

1. **Clean the pinion oil seal seat. Coat the seating edge of the new seal with a small amount of oil resistant sealer. Do not put sealer on the sealing lip. Drive the seal into the housing, using Tool T55P-5676-A.**
2. **Coat the inside of the pinion flange with a small quantity of rear axle lubricant and install the flange on the pinion shaft, using Tool-4858-E.**
3. Install the pinion attaching nut on the pinion shaft and torque it to 200-220 ft-lb.
4. Position the drive shaft in the original location, matching the previously made scribe marks, and install the attaching parts.
5. Torque the universal joint U-bolt attaching nuts to 15-20 ft-lb.
6. Raise the vehicle, remove the safety stands and then lower the vehicle to road position. Check the level of axle lubricant and add the specified lubriant as necessary.



E2391-A

FIG. 10 Spindle Lubrication

DANA FOUR-WHEEL DRIVE FRONT AXLE

Removal

1. Raise the vehicle on a hoist or jack and install safety stands under the radius arm brackets.
2. Follow the procedure detailed in Front Axle Shaft and Steering Knuckle Removal and remove the front wheels, tires, brake drums, brake backing plates, spindles and axle shaft.
3. Remove the hydraulic brake line brackets from each end of the axle without breaking the hydraulic connection. Disengage the hydraulic lines from the axle clips. Tie the lines to the frame to keep them out of the working area.
4. Disconnect the steering tie rod at the knuckle connecting rod ends and tie it out of the working area.

Disconnect the axle stabilizer bar.

5. Disconnect the front drive shaft at the pinion companion flange and universal joint. Secure the drive shaft out of the working area.
6. Lower the vehicle onto the safety stands and place a jack under the axle to support it while disconnecting it from the radius arms.
7. Each radius arm and cap is numbered from 1 through 100 for proper assembly, since they are manufactured as matched pairs. Remove the bolts attaching the radius arms to the radius arm caps. Remove the rubber insulators and roll the axle from under the vehicle, using the jack positioned in Step 6, above.

Installation

1. Position the front drive axle under the vehicle, using a floor jack, and install the radius arms, insulators and caps to the axle. The numbers enscribed on cap and arm should agree and be matched together. Torque the attaching bolts to specifications, tightening them diagonally in pairs.
2. Raise the vehicle to working height and install the drive shaft to the pinion companion flange at the universal joint. Torque the universal joint U-bolt nuts to specifications.
3. Connect the axle stabilizer bar. Connect the steering tie rod to the steering knuckle by means of the steering connecting rod ends. Torque the attaching nuts to specifications and install cotter pins.
4. Follow the procedure detailed in Front Axle Shaft and Steering Knuckle Installation and install the axle shafts, spindles and brake backing plates.
5. Position the hydraulic brake lines and brackets and install the retaining clips.
6. Install the front brake drums, wheels and tires. Adjust the front wheel bearings to specifications. Install the dust cap or locking hub cap and the wheel cover on each front wheel.
7. Lower the vehicle to running position and fill the axle housing with the specified

DISASSEMBLY AND ASSEMBLY

If the Ring Gear and Pinion are to be replaced, they must be replaced in matched sets. When new gear set is obtained, check the markings stamped on each gear (Fig. 11).

Disassembly

1. Remove the front drive axle from the vehicle as detailed in Dana Design Front 4-Wheel Drive Axle Removal.
2. Clean around the differential housing cover, and remove it. Discard the cover gasket. Remove the differential bearing caps.
3. Install the housing spreader and adapter (Fig. 12) making sure the tool hold-down clamp screws are tight. Spread the housing until the differential assembly can be forced out with a small pry bar. Do not spread the housing more than 0.020 inch to remove the differential assembly. Loosen the spreader thread immediately after lifting out the differential assembly to prevent springing the housing.
4. If the differential bearings are to be removed, refer to Specifications for the proper tool.
   A shim pack will be found behind each differential bearing cone. These shim packs control differential bearing preload and pinion and ring gear backlash. When the differential bearing cones are removed, these shim packs are usually damaged by the puller jaws and should be replaced with new shims.

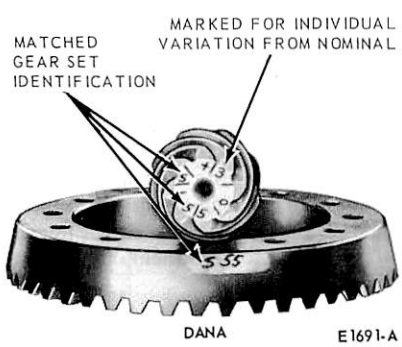


FIG. 11 Pinion and Ring Gear Markings—Dana

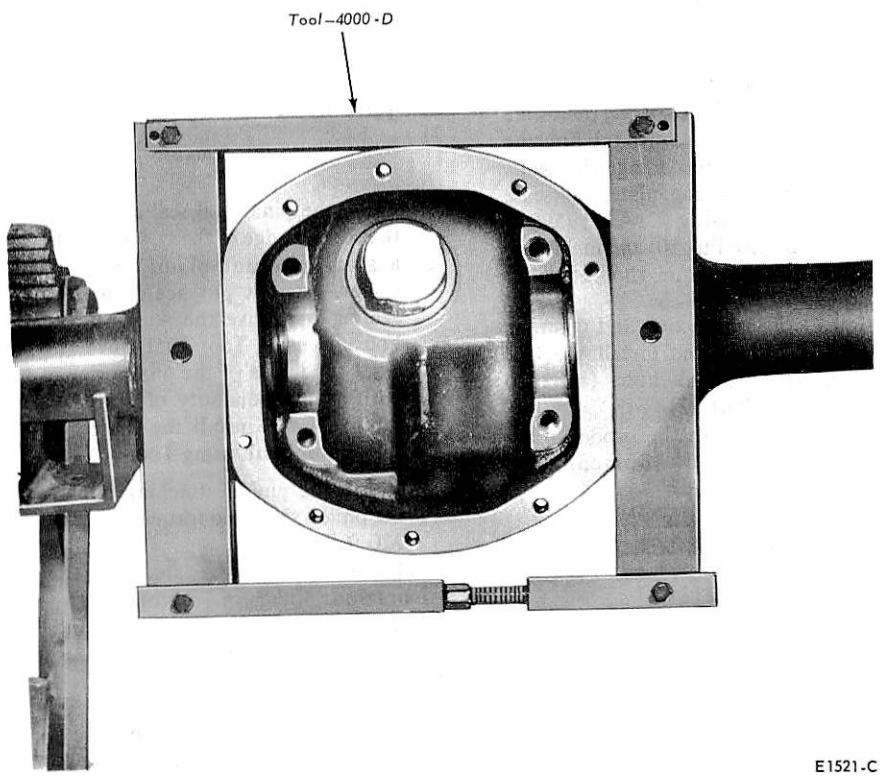

FIG. 12 Spreading Differential Housing

Measure each shim pack with a micrometer, shim by shim, and write down the total thickness and location of each pack.

5. Remove the ring gear from the differential case. With 2 screwdrivers remove differential pinion shaft locking rings. Remove the side gears and thrust washers. Steps 6, through 15 apply to limited slip (Trac-Lok) gear sets only. If working on a conventional differential, skip these steps.
6. To remove and install side gears, washers and clutch packs during disassembly and assembly requires special procedures and tooling. Use Kit T72L-4205-B (part of the 1972 Essential Kit, TKIT-1972, and also available separately). With this tooling it is necessary to use an appropriate step plate from the 1971 essential tool kit.

An axle shaft placed in a vise with the splines extending above the jaws of the vise not more than three inches, makes an excellent holding fixture after the case has been removed from the housing.

Position the Step Plate into the bottom side gear (Fig. 13). Apply grease to the centering hole of the Step Plate.

7. Position the Gear Rotating Tool into the top side gear (Fig. 14).
8. Lubricate the threads of the Forcing Screw and thread it into the Gear Rotating Tool. Guide the Forcing Screw into the Step Plate (Fig. 15).
9. Torque the Forcing Screw tight. This will move the side gears away from the differential pinion gears, and relieve the normal loaded condition. Using a piece of 0.030 thick shim or gauge stock, push out the differential spherical washers (Fig. 16).
10. Momentarily, loosen the Forcing Screw. **This step is very important to relieve the pressure of the clutch pack.**
11. Retighten the Forcing Screw until a very slight movement of the differential pinion gears is seen.
12. Slide the pawl of the Gear Rotating Tool (Fig. 17) between two of the side gear teeth. Pull the handle so the top side gear will rotate and also allow the differential pinion gears to rotate. Continue this until the differential pinion gears can be removed through the large openings in the case. When attempting to rotate the side gear, some tightening or loosening of the Forcing Screw will probably be required to permit the gear movement.
13. Retain the top side gear and clutch pack in the case with the hand and remove the Forcing Screw. Continue to hold the side gear and clutch pack and remove the Gear Rotating Tool (Fig. 18). Remove the top side gear and clutch pack. Keep the stack of plates and discs in exact order.
14. Turn the case so the flange, or ring gear side is up. As this is done, ease the Step Plate, side gear and clutch pack out of the case.
15. Remove the retainer clips from both clutch packs to allow separation of the discs and plates for cleaning and inspection. **Be sure to keep them in exact order** (Fig. 19).
16. Seals are installed in the axle housing near the differential bearings. If these seals are not to be replaced, pry them from the housing with a heavy screwdriver or similar tool.

FIG. 13 Step Plate in Position

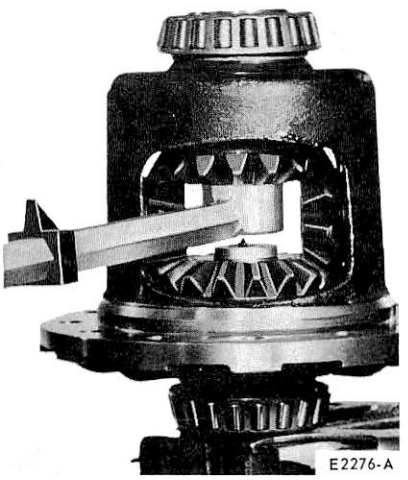

FIG. 14 Gear Rotating Tool in Position

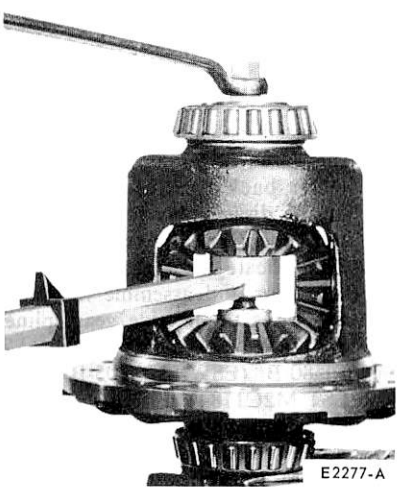

FIG. 15 Guiding the Forcing Screw into the Step Plate

FIG. 16 Removing Spherical Washers

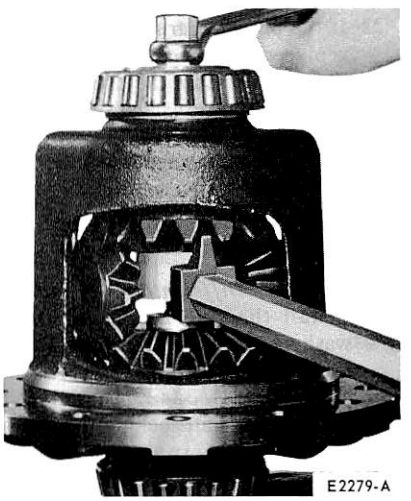

FIG. 17 Rotating Tool Pawl in Position

Use Tool T66T-3002-A to replace both seals at once. Position the seals in the respective bores and insert the tool, as shown in Fig. 20. Use a wrench to expand the tool until the seals are fully seated in the bores.

17. Hold the pinion shaft flange and remove the pinion shaft nut. Remove the flange.
18. Tap the pinion shaft out of the front bearing cone, using a rawhide mallet.
19. Remove the pinion bearing preload shim pack from the pinion shaft or from the housing.
20. If the pinion rear bearing cone is to be replaced, use the type of tool shown in Fig. 21.
21. Attach a side hammer puller tool to the pinion outer bearing cone and remove the bearing cone, slinger, and oil seal from the housing.
22. If the pinion bearing cups are to be replaced or the rear bearing cup removed for shim adjustment, refer to Specifications for the proper remover tools.
23. Clean and inspect the axle parts as detailed in Part 15-01.

ASSEMBLY

Conventional Differential

1. Install the side gears and thrust washers, pinions and thrust washers, and the pinion shaft in the differential case. Install the differential shaft locking pin.
2. Install the ring gear on the differential case, and torque the attaching bolts to specifications.

Trac-Lok Differential

1. Install the side gears and thrust washers. To do this, whether the original plates and discs or new ones are used, assemble them in exactly the same order as the originals. Refer back to illustrations used during disassembly for guidance in subsequent assembly operations.
2. Prelubricate the thrust face of the side gear and assemble the plates and discs to the side gear splines, prelubing each part with D2AZ-19580-B (ESW-M2C105-B) with EST-M2C118-A Friction Modifier Lubricant, both stacks.
3. Assemble the retainer clips to the ears of the plates. Make sure both clips are completely assembled or seated onto the ears of the plates. With the differential case positioned as shown, assemble the clutch pack and side gear into the case. Make sure the clutch pack stays assembled to the side gear splines, and that the retainer clips are completely seated into the pockets of the case. To prevent pack from falling out of the case, it will be necessary to hold them in place by hand while repositioning case on bench.
4. Reposition the case on the bench and assemble the step plate into the side gear. Apply a small amount of grease into the centering hole of the step plate.
5. Assemble the other clutch pack and side gear. Make sure the clutch pack stays assembled to the side gear

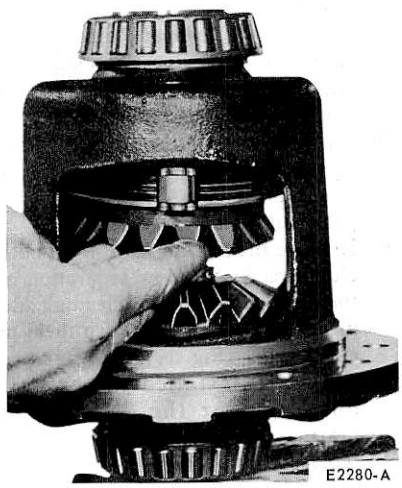

FIG. 18 Holding Clutch Pack

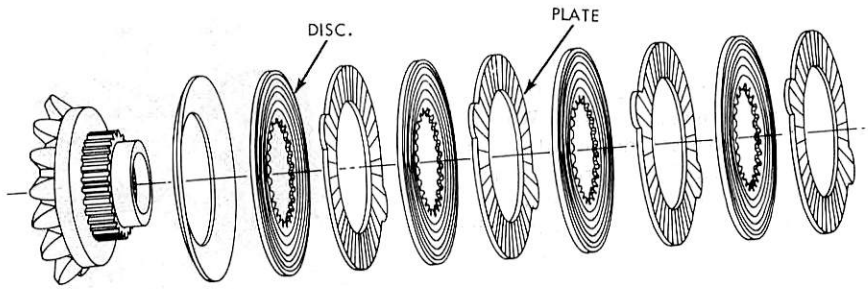

FIG. 19 Plates and Discs to Side Gear Exploded View

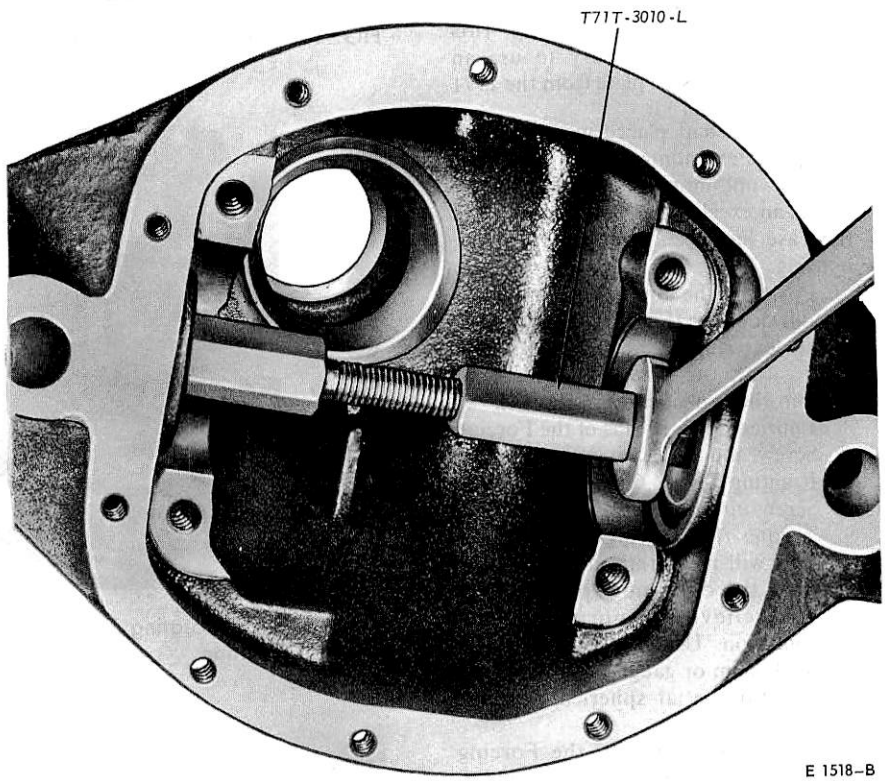

FIG. 20 Installing Inner Seals

splines, and that the retainer clips are completely seated into the pockets of the case.

6. Position the gear rotating tool into the top side gear and keep the side gear and rotating tool in position by holding with hand. Insert the forcing screw down through the top of case, and thread into the rotating tool until forcing screw contacts step plate.
7. With tools assembled to the case, position case onto the axle shaft (as a holding fixture) by aligning the splines of the side gear with those of the shaft.
8. Position both differential pinion gears opposite one another through the openings in the case. Be sure the holes of the gears are lined up with each other. Hold gears in place by hand.

Tighten forcing screw so that the side gears will move away from the differential pinion gears and relieve the loaded condition.

9. While holding the differential pinion gears in place, insert the pawl of the rotating tool between two of the side gear teeth. Pull on handle so that the top side gear will rotate and allow the differential pinion gears to rotate and enter into the case.

As mentioned under disassembly, it will probably be necessary to adjust the forcing screw by very slightly loosening or tightening until the required load is applied to allow the side gear and differential pinion gears to rotate.

10. Pull on tool until the handle hits the gear. Remove the pawl from between the gear teeth and reposition the handle and the pawl. Repeat the same operation until the holes of both differential pinion gears are lined up exactly with those of the case.

Prelubricate both sides of the pinion spherical washers with the specified lubricant.

11. Apply torque to the forcing screw to allow clearance to assemble the spherical washers.

Assemble washers into the case. Use a very small screwdriver to push washers into place. **Be sure the holes of the washers and gears are lined up exactly with those of the case.** Remove the forcing screw, rotating tool, and step plate.

Install the pinion shaft in the differential case. Install the differential shaft locking pin.

12. Install the ring gear on the differential case, and torque the attaching bolts to specifications.

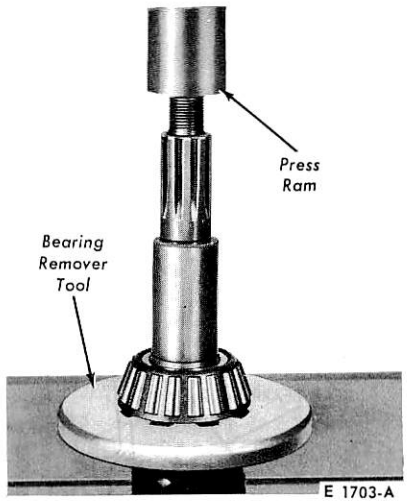

FIG. 21 Removing Pinion Bearing

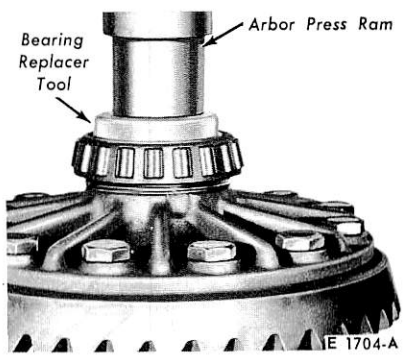

FIG. 22 Installing Differential Bearing

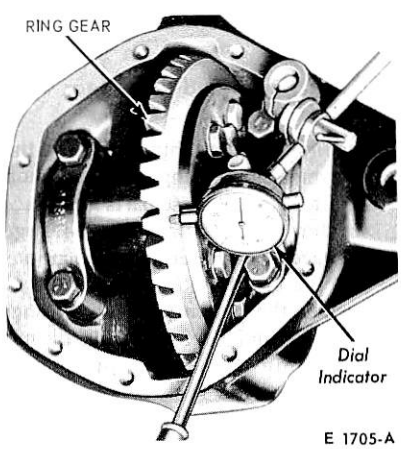

FIG. 23 Checking Differential End Play

Differential Bearing End Play Measurement— Conventional and Limited—Slip Differentials

1. Press the differential bearings onto the case without sims (Fig. 22). The bearings must bottom on the case shoulder.
2. Place the cups on the differential bearings and install the assembly in the housing. Install the bearing caps and tighten the cap bolts just enough to keep the bearing caps in place.
3. Mount a dial indicator on the axle housing, with the indicator button against the ring gear (Fig. 23).
4. Pry the differential assembly away from the dial indicator, using a screwdriver between the bearing cup and the case, and set the indicator at zero. Pry the differential assembly toward the indicator and note the indicator reading. This reading indicates the amount of shims needed behind the differential side bearings to take up the total clearance between the differential bearing cups and the case. Record this reading.
5. Remove the bearing caps and lift the differential assembly from the housing. Do not install shims under the differential bearings at this time. The total-clearance reading obtained in the above step must be integrated with a second reading to be obtained after the pinion has been installed and pinion depth has been adjusted. The two readings are used to calculate the shim thickness necessary to obtain proper differential bearing pre-load and ring gear back-lash, as well as end play adjustment.

Drive Pinion Installation and Depth Adjustment

As in all axles, two separate adjustments affect pinion and ring gear tooth contact, they are pinion depth (location) and backlash. On Dana axles, the pinion locating shim pack is installed between the pinion rear bearing cup and the carrier housing (Fig. 24). Therefore, adding shims moves the pinion toward the ring gear; removing shims moves the pinion away from the ring gear.

Estimated Shim Pack. If the original gear set is being installed, install the pinion with the original shim pack and check the pinion location with a depth gauge.

If the ring gear and pinion is being replaced, note that the original factory installed pinion locating shim is of the correct thickness to adjust for individual variations in both the carrier housing dimension and in the original gear set dimension. Therefore, to estimate the correct shim thickness for the new gear set to be installed, follow these steps:

1. Measure the thickness of the original pinion locating shim with a micrometer.
2. Note the shim adjustment number on both the old pinion and the new pinion. Each pinion gear is marked with an adjustment number.
3. Refer to specifications for the correct amount of shim thickness change. The amount that is shown under the new pinion shim adjustment number and in line with the old pinion number is the amount of change that should be made to the original shim thickness.

If the old pinion is marked 4, for example, and the new pinion is marked -2, the table indicates that 0.006 inch of shim stock should be added to the original shim pack.

If the original shim pack was lost or if a new axle housing is being installed, substitute a nominal 0.030 inch shim for the original, and repeat the foregoing steps for a trial build-up. If any further shim change is necessary, it will be indicated in the depth gauge check.

A new ring gear and pinion should always be installed in an axle as a matched set (never separately). Be sure that the same matching number appears on both the drive pinion and the ring gear.

Install the pinion with the estimated shim pack, and check the pinion location with a depth gauge as outlined in the following procedure.

Depth Gauge Check

1. Install the pinion locating shim pack and pinion bearing cups. Refer to Specifications for the proper tool.
2. Press the rear bearing onto the pinion shaft. Refer to Specifications for the proper tool.
3. Position the pinion and rear bearing assembly by inserting it from the inner side of the axle housing. Position the front bearing cone (without preload shim pack) and the universal joint flange on the pinion shaft. Press all these parts into place under a press or with a flange replacer tool. Refer to Specifications for the proper tool.
4. Install the pinion shaft flat washer and nut, and carefully torque the nut until pinion bearing preload is between 20-40 in-lbs. As the nut is torqued, rotate the pinion shaft in both directions to set the bearing rollers.
5. Check the pinion bearing preload (Fig. 25). Disregard the torque required to start the pinion rotating.

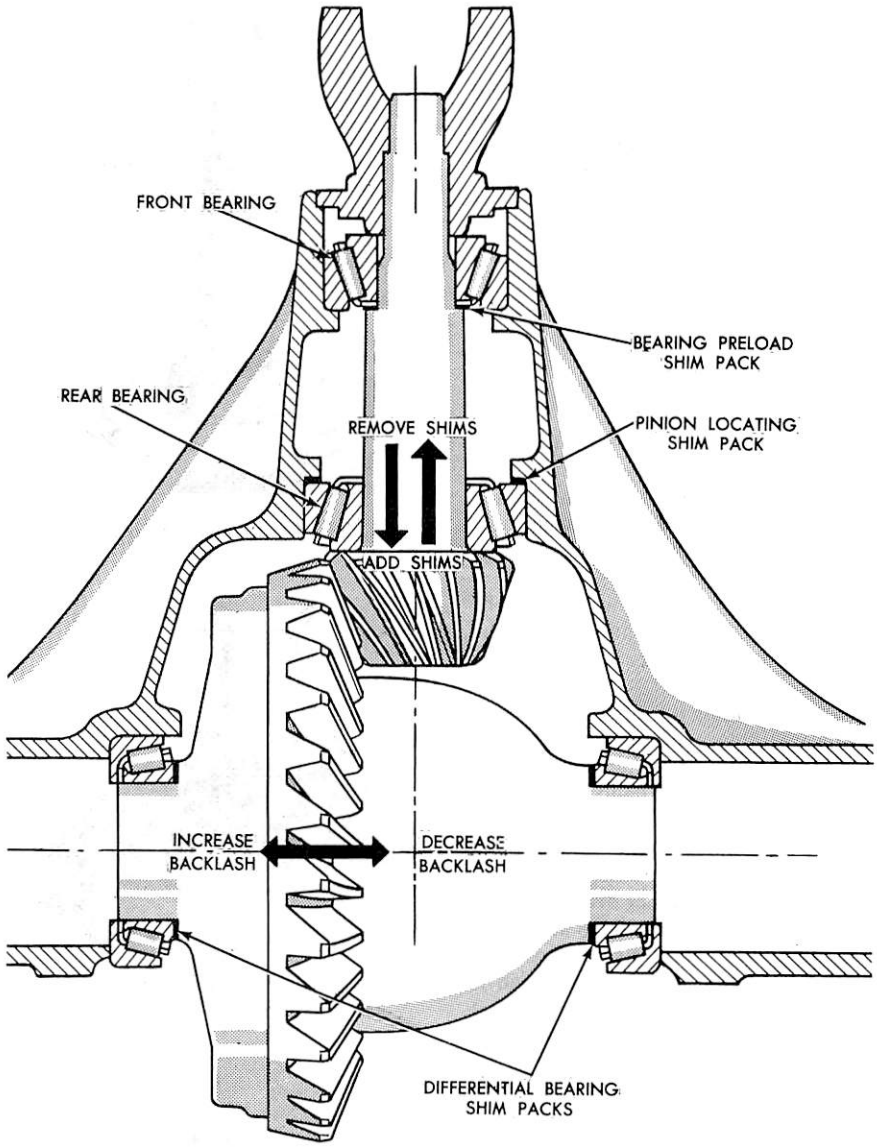

FIG. 24 Pinion and Ring Gear Tooth Contact

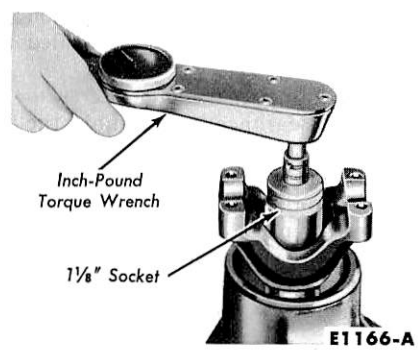

FIG. 25 Checking Pinion Bearing Pre-Load

The specified torque of 10 to 30 in-lbs refers to the torque required to keep the pinion rotating after it has been started.

With the pinion installed in the housing and the bearing preload within limits, check the depth setting (actual assembly dimension) with the gauge shown in Fig. 26.

Place the gauge shaft and discs in the differential bearing pockets and securely tighten the bearing caps.

6. Attach the dial indicator to its holder and place it on the gauge block. Place the gauge block squarely on the pinion gear and squarely against the gauge shaft.
7. With the indicator button resting on the flat of the gauge block, set the dial face to read zero. Swing the indicator (Fig. 26) to the highest point on the gauge shaft and note the reading at the highest point. The highest point on the gauge shaft is the point of highest indicator reading while the indicator hand is moving clockwise. When the hand reverses and starts moving counterclockwise, the highest point has been passed.

The indicator reading at the highest point on the gauge shaft shows the actual assembly dimension with reference to the nominal assembly dimensions for this axle is 2.625 inches. The nominal dimension is the distance from the ground surface on the pinion gear rear face to the center line of the ring gear. The highest point on the installed gauge shaft is exactly 1/2 inch higher than the ring gear centerline. The installed gauge block height is exactly 1/2 inch greater than the nominal assembly dimensions for the axle.

When the gauge block is resting on a zero-marked pinion installed exactly at the nominal assembly dimension, the top of the gauge block and the highest point on the gauge shaft are exactly the same distance from the pinion gear rear face. In this case, the indictor, having been set at zero on the gauge block, will read zero when moved to the highest point on the gauge shaft. A plus or minus reading on the indicator at the highest point on the gauge shaft indicates, therefore, that the actual assembly dimension is not the same as the nominal assembly dimension. The plus and minus indicator readings are translated directly into plus and minus variations from the nominal assembly dimension.

The indicator reading at the highest point on the gauge shaft must correspond with the pinion gear marking, if the actual assembly dimension is correct. For example, a pinion marked minus 3 is installed at the proper depth when the indicator reads minus 3 at the highest point on the gauge shaft. Likewise, a pinion marked plus 3 is installed at the proper depth when the indicator reads plus 3 at the highest point on the gauge shaft.

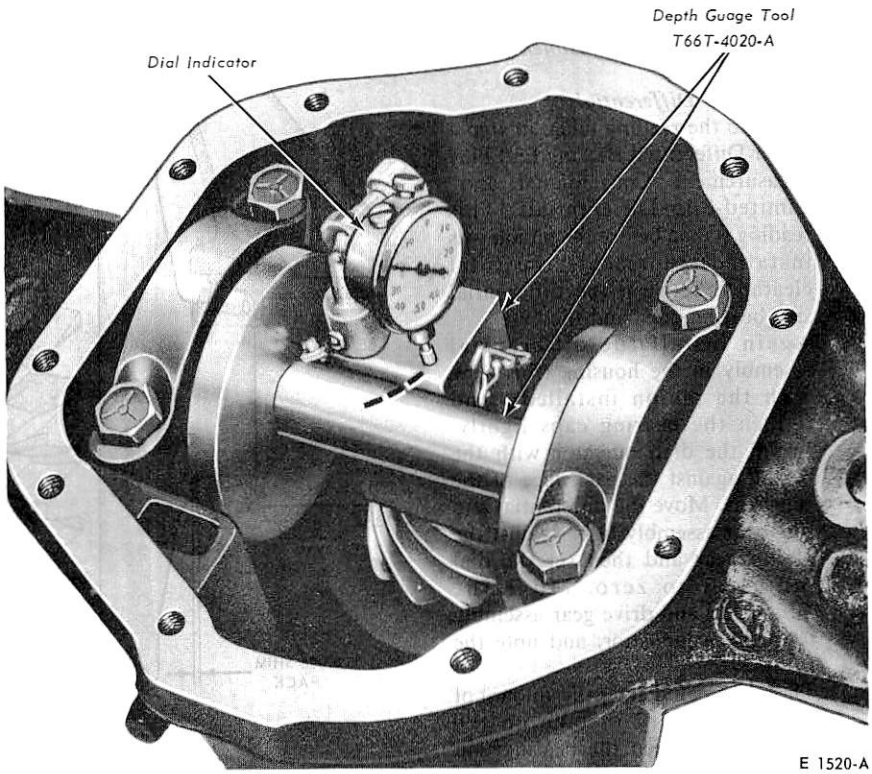

FIG. 26 Checking Pinion Depth

A plus reading (clockwise from zero) at the highest point on the gauge shaft with a zero-marked pinion, means that the actual assembly dimension is too great in the amount of the plus reading. To correct, add shims in thousandths of an inch that correspond to the plus reading. For example, an indicator reading of plus 10 with a zero marked pinion means that 0.010 inch in shims must be added to the rear bearing cup pack. The addition of shims will move the pinion gear closer to the ring gear and decrease the actual assembly dimension (Fig. 24).

Likewise, a minus reading (counterclockwise from zero) at the highest point on the gauge shaft with a zero marked pinion, means that the actual assembly dimension is deficient in the amount of the minus (-) reading. To correct, remove shims in thousandths of an inch equal to the minus reading. This will increase the actual assembly dimension.

Whenever the pinion rear bearing cup shim pack is changed, install the pinion and recheck the pinion depth.

8. **After the pinion depth has been adjusted and checked, remove the universal joint flange and front bearing. Add or subtract from the original front pinion bearing preload shim pack, the same amount in thousandths of an inch that was added or subtracted from the shim pack behind the rear bearing cup (Fig. 24). Install the bearing preload shim pack, the outer bearing, the universal joint flange, washer and nut. Torque the flange nut to 200-220 ft-lbs on all models.**
9. Check the pinion bearing preload (Fig. 25). The preload should be 20-40 inch-pounds. Add shims to decrease preload and remove shims to increase preload.

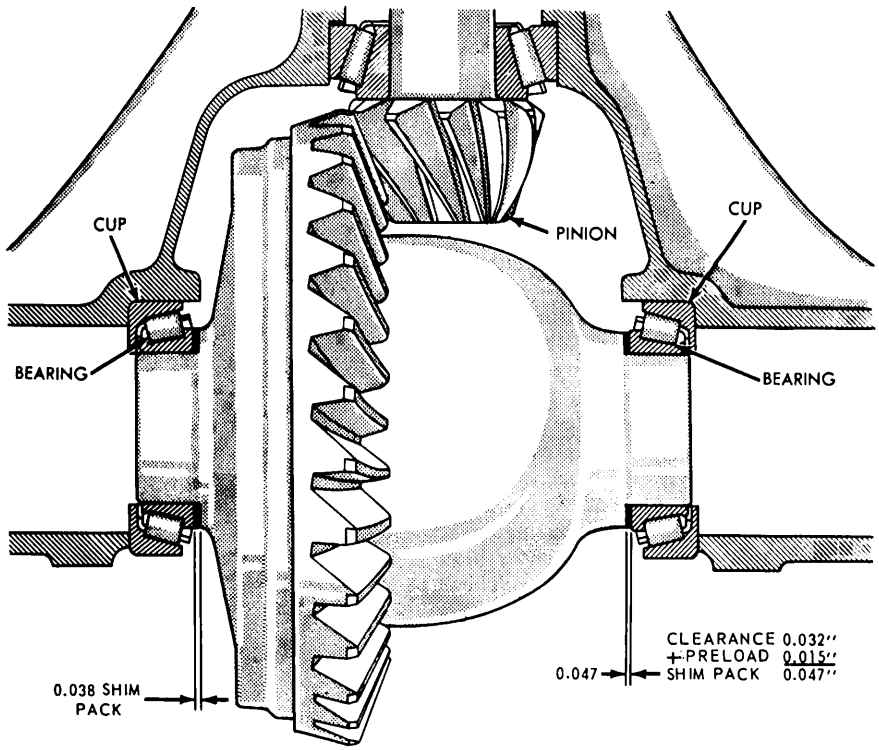
If the original bearing preload shim pack has been lost or there is reason to believe that it was not correct, install a 0.065-inch shim pack for a trial build-up. Check the pinion bearing preload and adjust as necessary to obtain 20-40 in-lbs preload on new bearings or 10-25 in-lbs on used bearings.

10. When the pinion bearing preload is correct, remove the universal joint flange. Install the oil slinger on the outer side of the front pinion bearing

and install the oil seal. Refer to Fig. 20 for the proper seal installer tool.

Differential Bearing Pre-Load and Ring Gear Backlash Adjustment—Conventional and Limited—Slip Differentials

1. Refer to the reading taken in step 4 under Differential Bearing End Play Measurement Conventional and Limited-Slip Differentials. This reading (taken before the pinion was installed) represents the total clearance between the differential side bearing cups and the case.
2. Again install the differential assembly in the housing (this time with the pinion installed), and tighten the bearing caps lightly. Install the dial indicator with the button against the back face of the ring gear. Move the differential and ring gear assembly tight against the pinion gear and then set the dial indicator to zero. Move the differential and drive gear assembly toward the indicator, and note the reading.
3. This reading indicates the amount of shims necessary to take up the clearance between the bearing cup and the case at the ring gear side of the differential assembly. Subtract this reading from the previously recorded total reading to obtain the amount of shims necessary to take up the clearance between the bearing cup and the case at the pinion side of the differential. Increase this pinion-side shim pack by an additional 0.015 to 0.020 inch in order to provide correct bearing preload and backlash. EXAMPLE (Fig. 27): Total Clearance previously recorded.....0.070 inch Less reading in foregoing step 2 (Amount of shims necessary to take up clearance at ring gear side) .....0.038 inch Shims necessary to take up clearance at pinion side.....0.032 inch Plus 0.015 inch shims for preload and backlash. Total amount of shims at pinion side..... 0.047 inch.



E 1716-A

FIG. 27 Differential Bearing Pre-Load and Ring Gear Backlash

4. Remove the bearing caps, and lift the differential assembly from the housing. Remove the differential side bearings, and install the proper amount of shims on each side of the differential case. Press the side bearings onto the case until they are firmly seated against the shims.
5. Install the housing spreader, spread the housing not more than 0.020 inch, and install the differential assembly. Install the bearing caps, and remove the spreader. Install and torque the cap bolts to specifications.
6. Install a dial indicator to check the backlash at four equally spaced points around the ring gear. The backlash must be held to 0.004-0.009 inch and cannot vary more than 0.002 inch between positions checked. If the backlash does not fall within these specifications, change the shim packs behind both differential side bearings, as required.
7. Check gear tooth contact pattern as given in Fig. 3 in Part 15-01.
8. Position a new gasket on the rear face of the axle housing, and install the rear cover and ratio identification tag. Torque the cap screws to 30-40 ft-lbs.
9. Install the axle in the vehicle according to the instructions under Removal and Installation.

DESCRIPTION

F-100 4-WHEEL DRIVE FRONT AXLES—DANA

A unique front wheel drive axle is provided on the F-100 vehicle. An open yoke is welded to the outer ends of the axle housing. This construction makes for a very strong spindle area. Power to drive the front wheels is transmitted through open Cardan-type universal joints. Ball and socket joints are now used. A new spindle bore seal is used. The seal is installed on the axle shaft rather than being retained in the spindle. Due to its' special design, the seal acts as a slinger as well as a seal (see Figs. 1 and 2).

The differential section of the Dana Model 447F axle is similar in design (but not in size) to the other Dana units used on Ford vehicles (Fig. 3). The differential carrier is integral with the axle housing. Adjustment of the side carrier bearings is accomplished by means of shims placed between the bearings and the differential case. The carrier side bearings are pre-loaded by the squeezing action of the housing. A spreader must be used (Fig. 4) on the axle housing to relieve the tension on the differential bearings and permit removal or installation of the differential. Pinion depth is controlled by a shim pack located to the rear of the pinion bearing. Pinion bearing preload is controlled by variable-size spacers. Where necessary, special service tools have been designed and are available to service the Dana axle used in the F-100 vehicles.

The front axle is of the integral carrier-housing, hypoid gear type, in which the centerline of the drive pinion is mounted below the centerline of the ring gear.

The integral pinion gear and shaft is supported by two opposed tapered roller bearings which are assembled in the forward side of the carrier housing. Pinion locating shims, installed between the rear bearing cup and the cup seat, control the drive pinion depth adjustment. The pinion bearing preload is controlled by shims located between the pinion front bearing and the shoulder on the drive pinion shaft.

The differential case assembly is supported by two opposed tapered roller (side) bearings and cups, which are retained in the housing by removable caps. Shims, installed between each differential side bearing and the shoulder on the case, perform three functions: they take up the differential case side clearance: they adjust the backlash between ring gear and pinion: and they establish differential side bearing preload.

A cover on the front of the carrier housing provides access for inspection, removal and installation of the differential assembly and drive pinion. A metal tag, stamped with the gear ratio plus the number of teeth on the ring gear and pinion, is secured to the housing by one of the cover bolts.

Vehicles equipped with limited-slip differential assemblies will have an additional metal tag identification attached to one of the cover bolts.

FRONT WHEEL DRIVE HUB-LOK HUB

The optional free-running hub available for the Dana front axle is the internal locking type.

OPERATION

Lock Position

When the transfer case is to be shifted into the position for driving the front axle, the hub lock pointer on the center bar must point to the notch under the word LOCK on the retaining plate. If the clutch teeth do not engage with the knob turned to this position, the clutch teeth are butted and a slight movement of the wheel in either direction will complete the lock. The front axle will now drive the wheel. Do not operate in four-wheel drive with the hubs disengaged.

Free Running Position

When the transfer case is to be shifted into the position for driving the rear axle only, turn the hub lock pointer on the center bar so it points to the notch under the word FREE on the retaining plate. This will disengage the clutch teeth and thus unlock the wheel hub from the axle shaft. The wheel will now turn free on the axle.

Be certain that the transfer case is shifted into 2-wheel drive position before disengaging the hub lock.

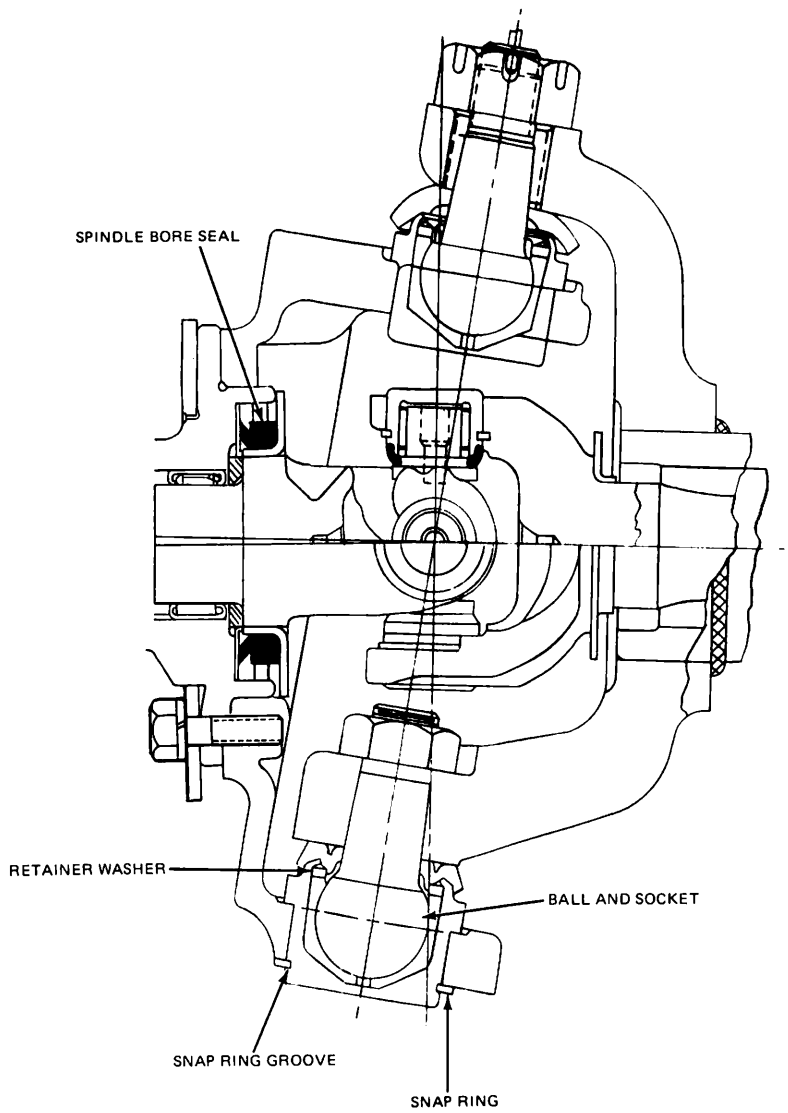

FIG. 1 Ball Joint and Seal Assemblies

FRONT WHEEL BEARING ADJUSTMENT

Front wheel bearing adjustment is covered in Part 11-12.

DRIVE PINION OIL SEAL

Removal

The drive pinion oil seal can be replaced without removing the axle assembly from the vehicle. Compounded or synthetic rubber seals do not require soaking in oil.

1. Raise the vehicle on a hoist or raise the front end of the vehicle with a jack. Install safety stands under the frame rails and lower the jack or hoist far enough to allow the axle to drop into the rebound position for working clearance.
2. Scribe marks on the companion flanges and U-joints for correct positioning at assembly, and remove the drive shaft.
3. Using Tool T57T-4851-B to hold the pinion companion flange, remove the pinion shaft nut.
4. Using Tool T56L-4851-C, remove the companion flange.
5. Using Tool-1175-AB, puller, in combination withslide hammer T50T-100-A, remove the pinion oil seal.

Installation

1. Clean the pinion oil seal seat. Coat the sealing edge of the new seal with a small amount of oil resistant sealer. **Do not put sealer on the sealing lip.** Drive the seal into the housing, using Tool T55P-4676-A.
2. Coat the inside of the pinion flange with a small quantity of lubricant (ESW-M2C105-B) D2AZ-19580-B, and install the flangs on the pinion shaft, using Tool-4858-B.
3. Install the pinion attaching nut on the pinion shaft and torque it to 200-220 ft-lb.
4. Position the drive shaft in the original location, matching the previously-made scribe marks, and install the attaching parts.

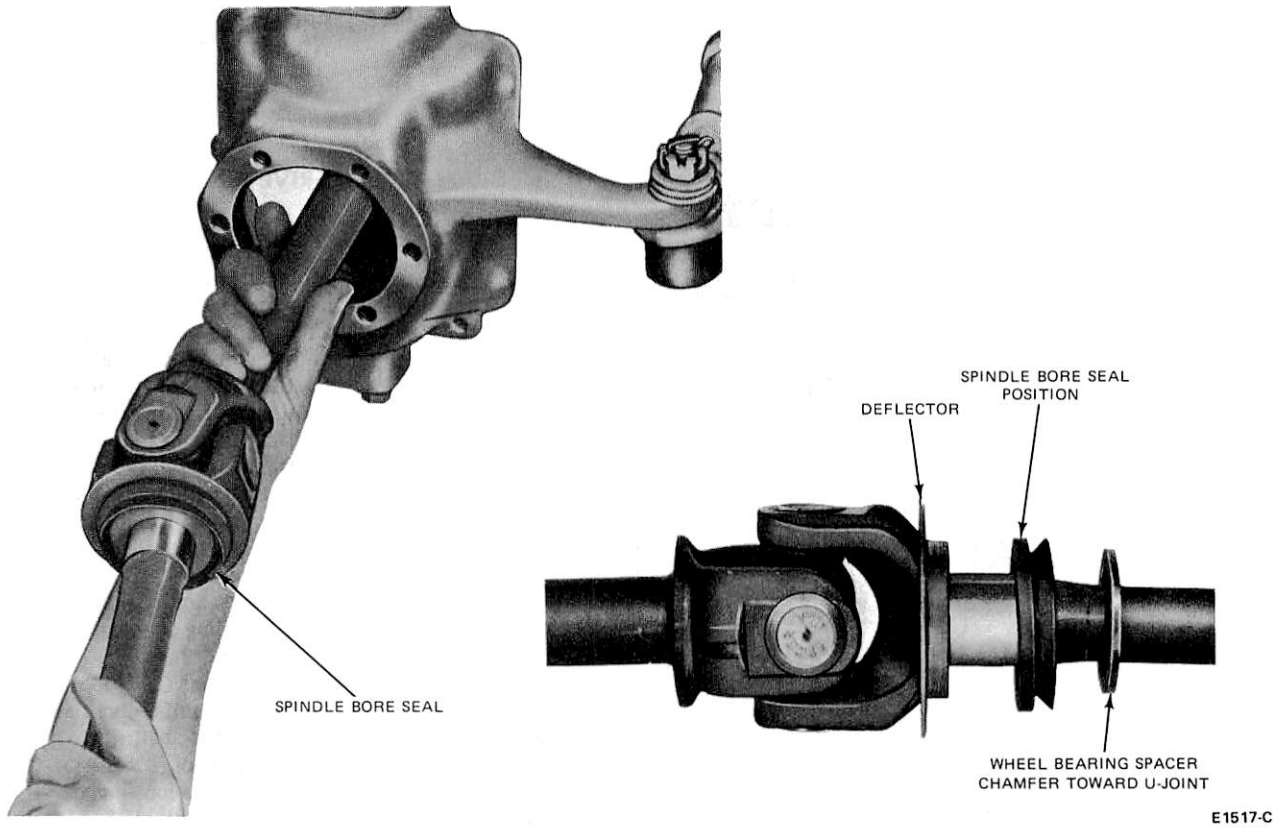

FIG. 2 Views of Seal Details

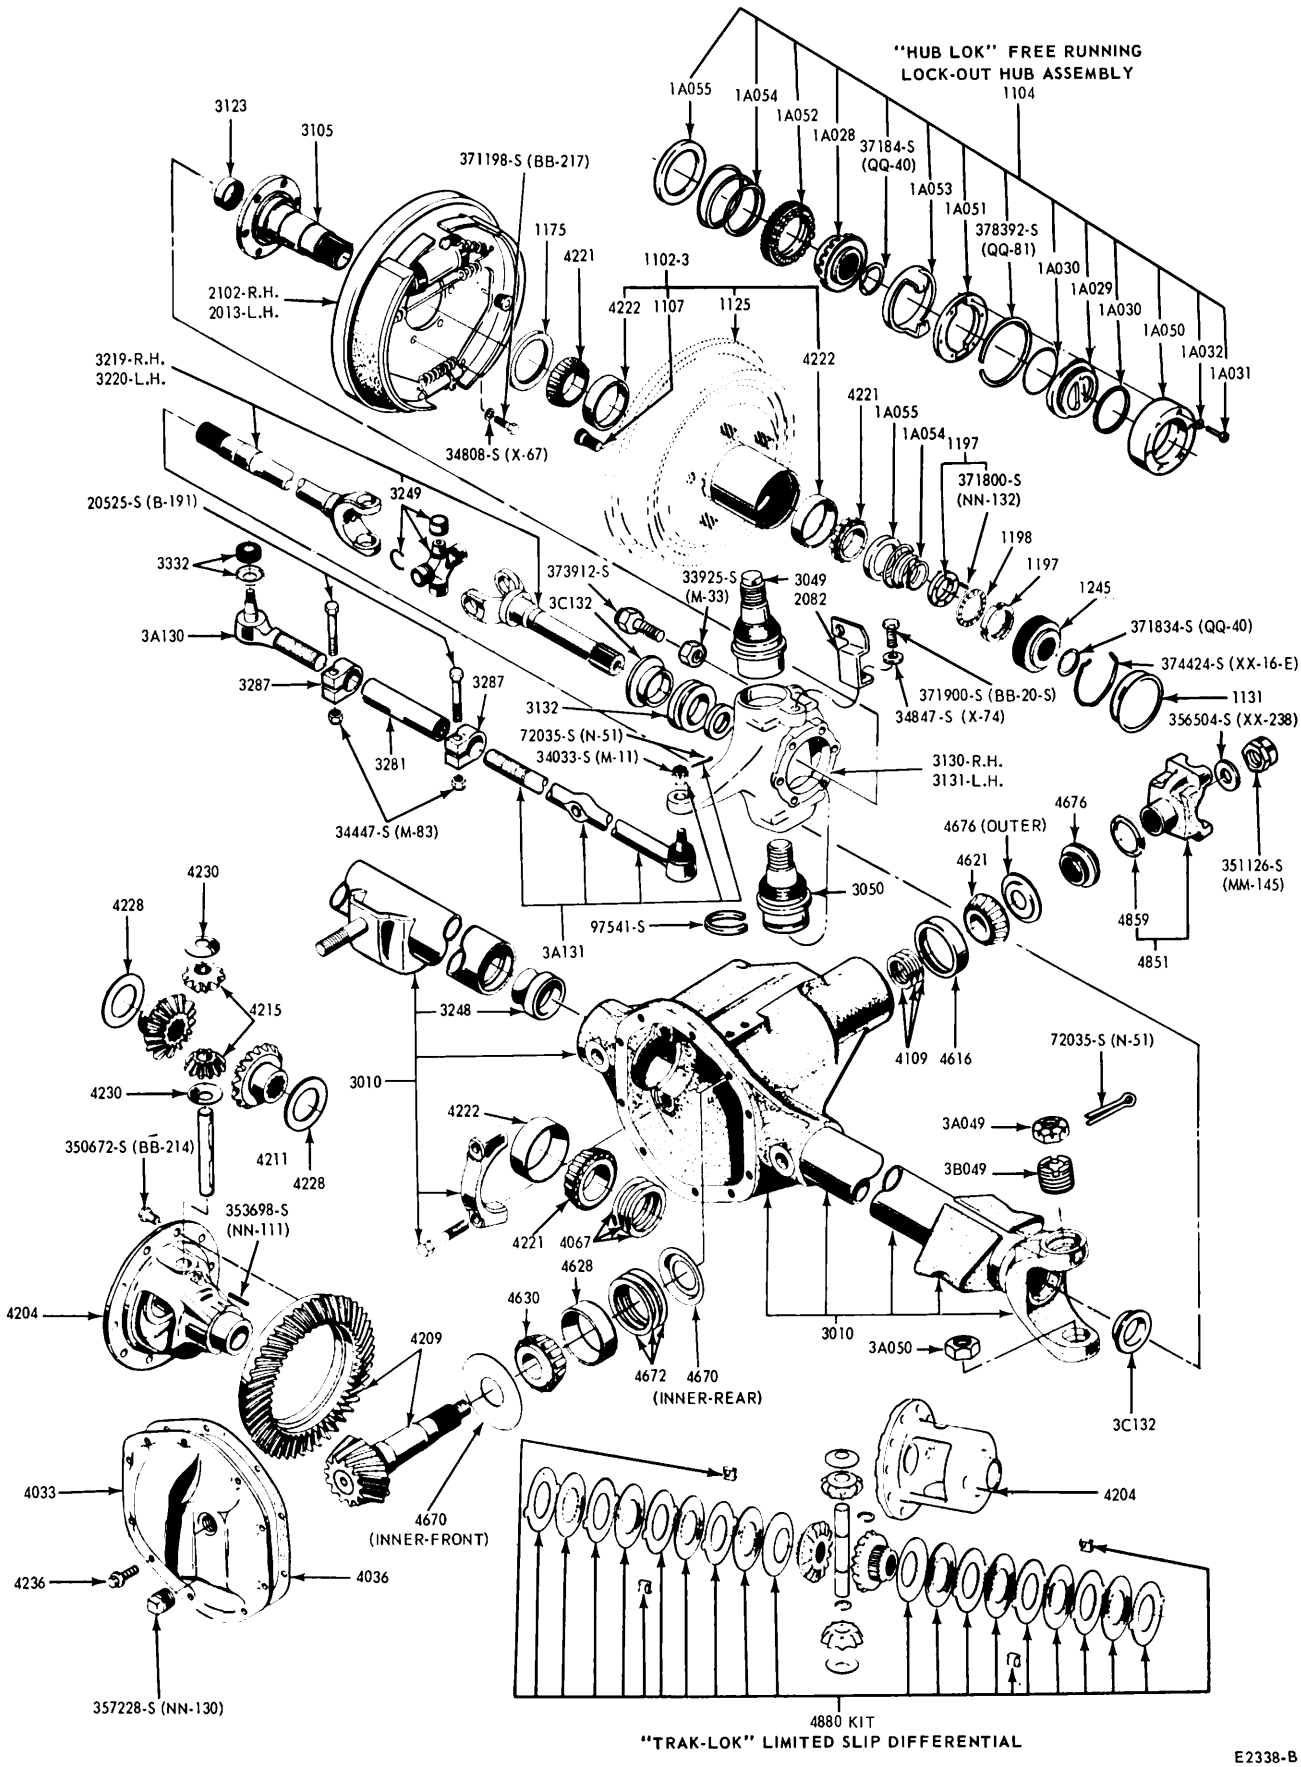

FIG. 3 Front Axle Assembly Complete—Exploded View

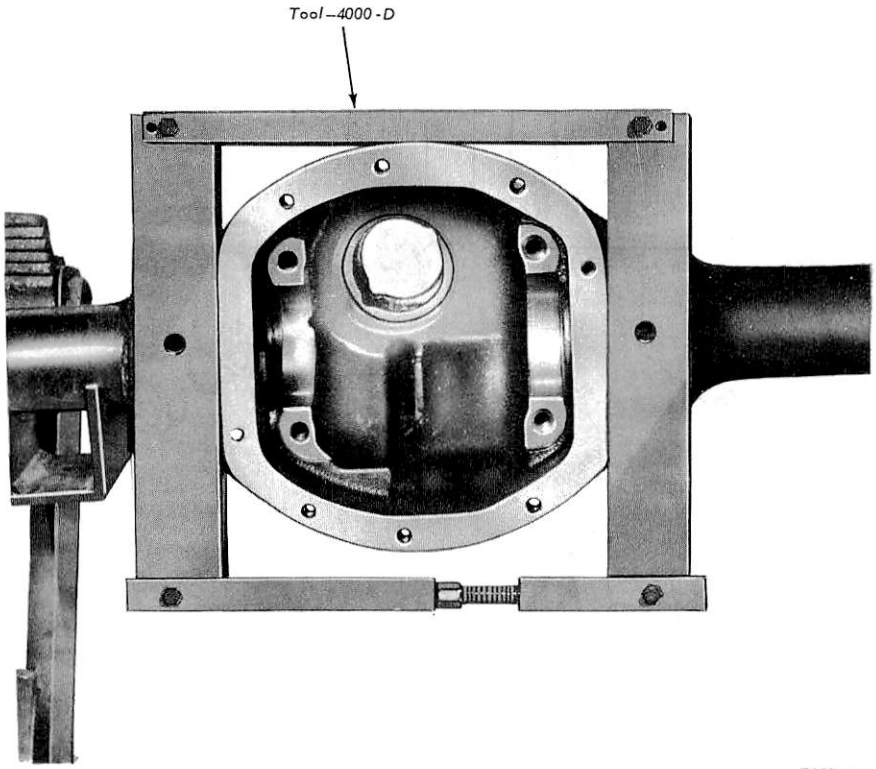

FIG. 4 Spreading Differential Housing

5. Torque the universal joint U-bolt attaching nuts to 15-20 ft-lb.
6. Raise the vehicle, remove the safety stands and then lower the vehicle to road position. Check the level of axle lubricant and add the specified lubricant as necessary.

REMOVAL AND INSTALLATION

FRONT AXLE SHAFT AND STEERING KNUCKLE

The removal and installation of these parts can be accomplished by following the step by step procedures in Part 15-30 under Removal and Installation, with just one exception. Under step 10 to remove the bottom socket it is necessary to first remove the snap ring at the bottom, for F-100 vehicles.

FRONT WHEEL DRIVE HUB-LOX HUB

Follow the procedures in Part 11-12.

F-100 4 x 4 FRONT AXLE HOUSING

Removal

1. Raise the vehicle on a hoist or jack and install safety stands under the radius arm brackets.
2. Follow the procedure detailed in Front Axle Shaft and Steering Knuckle Removal in Part 15-30, and remove the front wheels, tires, brake drums, brake backing plates, spindles and axle shafts.
3. Remove the hydraulic brake line brackets from each end of the axle without breaking the hydraulic connection. Disengage the hydraulic lines from the axle clips. Tie the lines to the frame to keep them out of the working area.
4. Disconnect the steering tie rod at the spindle connecting rod ends. Disconnect the axle stabilizer bar.
5. Disconnect the front drive shaft at the pinion companion flange and universal joint. Secure the drive shaft out of the working area.
6. Lower the vehicle onto the safety stands and place a jack under the axle to support it while disconnecting it from the radius arms.
7. Each radius arm and cap is marked for proper assembly, since they are manufactured as matched pairs (parts are numbered 1 through 100). Remove the bolts attaching the radius arms to the radius arm caps. Remove the rubber insulators and roll the axle from under the vehicle using the jack positioned in Step 6, above.

Installation

1. Position the front drive axle under the vehicle, using a floor jack, and install the radius arms, insulators and caps to the axle. Numbers on radius arm and cap should be alike and together. Torque the attaching bolts to specifications, tightening them diagonally in pairs.
2. Raise the vehicle to working height and install the drive shaft to the pinion companion flange at the universal joint. Torque the universal joint U-bolt nuts to specifications.
3. Connect the axle stabilizer bar. Connect the steering tie rod to the spindle arms by means of the steering connecting rod ends. Torque the attaching nuts to specifications and install the cotter pins.
4. Follow the procedure detailed in Front Axle Shaft and Spindle Arm Installation and install the axle

shafts, spindles and brake backing plates.
5. Position the hydraulic brake lines and brackets and install the retaining clips.
6. Install the front brake drums, wheels and tires. Adjust the front wheel bearings to specification (refer to Group 11, Part 12). Install the dust cap or locking hub cap and the wheel cover on each front wheel. If a dust cap is used, install it with a coat of non-hardening sealer on the sealing surface.
7. Lower the truck to running position and fill the axle housing with the specified lubricant.

DISASSEMBLY AND ASSEMBLY

PINION, DRIVE GEAR AND DIFFERENTIAL REPAIR

For major repair operations, refer to procedures outlined in Part 15-30, particularly for removing side gears and washers of limited slip axles from the differential gear case. For F-100 vehicles, when doing this operation use Kit T71T-4205-A (part of the 1971 Essential Kit), TKIT-1971-F or FX, and also available separately (See Disassembly and Assembly).

DESCRIPTION

F-250 4-WHEEL DRIVE FRONT AXLES—DANA

Dana-design front-drive axles are provided for F-250 Ford trucks. Dana Model S 44-6CF and 44-6CF-HD are used on the F-250. The Dana Model 44-6CF and 44-6CF-HD used on the F-250 continues the use of the spherical, closed spindle and enclosed universal joint as in previous models.

Other than the unique parts required for front-wheel drive, these axles are mechanically identical to other Model 44 axles. It should be noted that the free running Hub-LOK hub is standard equipment.

ADJUSTMENTS

FRONT WHEEL BEARING ADJUSTMENT

Refer to Part 11-12 for front wheel bearing adjustment procedures.

FRONT AXLE SHAFT AND STEERING KNUCKLE

Removal

1. Raise the vehicle on a hoist.
2. Remove the front wheel free running hub; then remove the front wheel hub and drum as an assembly (Fig. 2). Refer to Group 11 and 12, for procedures.
3. Place a drain pan under the steering knuckle assembly (Fig. 1).
4. Remove the cap screws which retain the brake backing plate and spindle to the steering knuckle. Remove the brake backing plate and spindle (Fig. 3). **It is not necessary to disconnect the hydraulic brake flex line before removing the brake backing plate from the spindle. Support the brake backing plate so that the brake hose is not damaged.**
5. Remove the axle shaft.
6. Disconnect the steering drag link from the steering knuckle (Fig. 3).
7. Disconnect the spnindle connecting (tie) rod at both ends.
8. Remove the unitized seal from the steering arm (Fig. 1).
9. Remove the upper and lower king pin bearing caps and shims.
10. Remove the steering knuckle from the housing (Fig. 4). Remove the bearing cones.
11. If the bearing cups are to be removed from the housing, use the tool shown in Fig. 5.

Installation

1. If new seals are to be installed at the steering knuckle, place the new unitized seal assembly on the axle housing tube (Fig. 1). The seal assembly should be installed with the split up to prevent lubricant leakage.
2. Install the upper and lower king pin bearing cups in the axle housing yoke with handle T53L-200-A and driver T57P-4625-A.
3. Place the king pin bearing cones in the cups. Retain the lower bearing in place with multi-purpose lubricant C1AZ-19590-B
4. Place the steering knuckle over the yoke, and then install the lower and upper king pin bearing caps (Fig. 4). Install the old shims for a trial build-up. Torque the bearing cap bolts and stud nuts to specifications.
5. Check the steering knuckle bearing preload (Fig. 6). It should be between 5-10 ft.-lbs. for 6CF, and 10-15 ft.-lbs. for 6CFHD. Adjust the

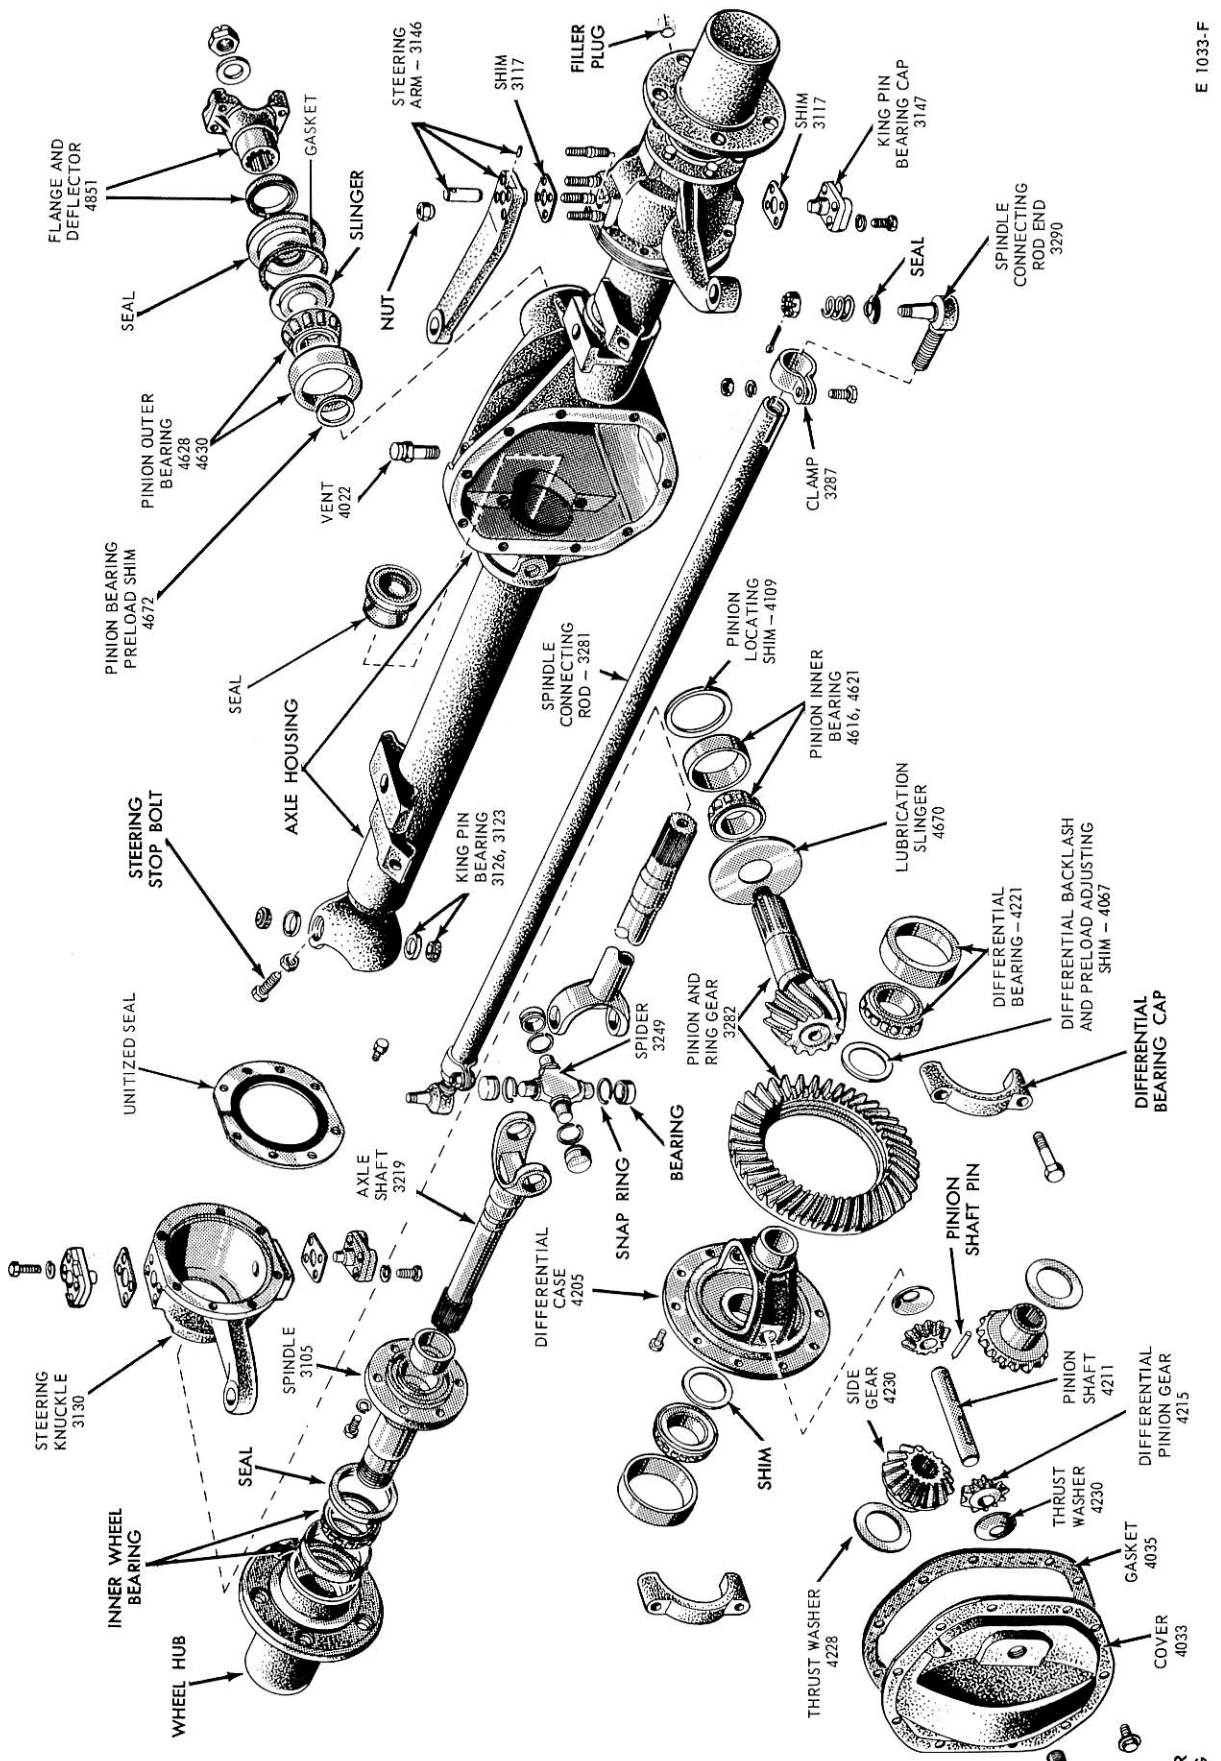

FIG. 1 Front Drive Axle Disassembled

shim thickness at the bearing caps, as required, to obtain the proper preload.

6. Install the knuckle seals as shown in Fig. 1 and torque the retaining screws to 10-15 ft.-lbs.
7. Connect the spindle connecting (tie) rod and the drag link.
8. Install the axle shaft.
9. Position the spindle and the brake backing plate on the steering knuckle, and then install the retaining cap screws. Torque the screws to 30-40 ft.-lbs. (Fig. 3). Install the oil baffle.
10. Install the wheel inner bearing cone on the spindle. Install the wheel hub and disc as an assembly; then install the free running Hub-Lok hubs (refer to Group 11, Part 12).
11. Fill the steering knuckle with the proper grade and amount of lubricant. Refer to Group 11, Part 12 for proper lubricant.

DRIVE PINION OIL SEAL

Removal

The drive pinion oil seal can be replaced without removing the axle assembly from the vehicle. Compounded or synthetic rubber seals do not require soaking.

1. Raise the vehicle on a hoist or raise the front end of the vehicle with a jack. Install safety stands under the frame rails and lower the jack or hoist far enough to allow the axle to drop into the rebound position for working clearance.
2. Scribe marks on the companion flanges and U-joints for correct positioning at assembly, and remove the drive shaft.
3. Using Tool T57T-4851-B to hold the pinion companion flange, remove the pinion shaft nut.
4. Using Tool T56L-4851-C, remove the companion flange.
5. Using Tool-1175-AB, puller, in combination with slide hammer T50T-100A, remove the pinion oil seal.

Installation

1. Clean the pinion oil seal seat. Coat the sealing edge of the new seal with a small amount of oil resistant sealer. **Do not put sealer on the sealing lip.** Drive the seal into the housing, using Tool T55P-4676-A.
2. Coat the inside of the pinion flange with a small quantity of rear axle lubricant and install the flange on the pinion shaft, using Tool-4858-B.
3. Install the pinion attaching nut on the pinion shaft and torque it to 200-220 ft-lbs.
4. Position the drive shaft in the original location, matching the previously-made scribe marks, and install the attaching parts.
5. Torque the universal joint U-bolt attaching nuts to 15-20 ft-lb.
6. Raise the vehicle, remove the safety stands and then lower the vehicle to road position. Check the level of axle lubricant and add the specified lubricant as necessary.

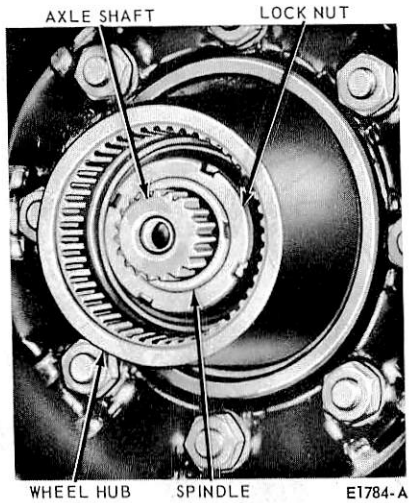

FIG. 2 Front Wheel Hub—4-Wheel Drive

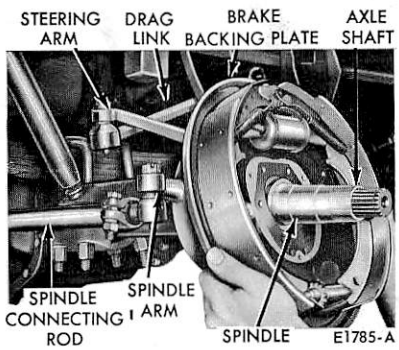

FIG. 3 Removing Brake Backing Plate

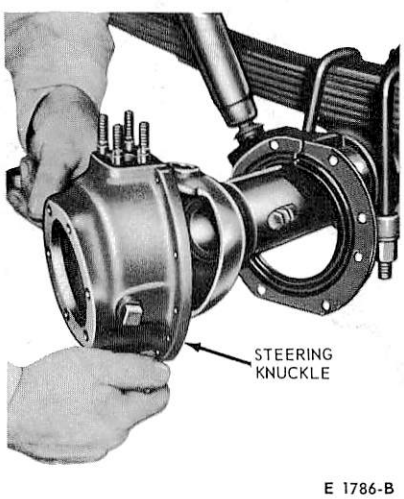

FIG. 4 Removing or Installing Steering Knuckle

FRONT WHEEL DRIVE HUB-LOK HUB

Front wheel drive free-running lock-out hub assemblies are standard on the F-250 4 x 4 model trucks.

An external design lock-out hub assembly is standard for the Model 446CFHD front drive axle. Refer to Part 11-12 for complete service procedures.

OPERATION—EXTERNAL TYPE

(Locked) Position

When the transfer case is to be shifted into the position for driving the front axle, turn the actuating knob so that it is aligned with the word lock stamped on the retainer cap. If the clutch teeth do not engage with the knob turned to this position, the clutch teeth are butted and a slight movement of the wheel in either direction will complete the lock. The front axle will now drive the wheel.

F-(Free) Position

When the transfer case is to be shifted into the position for driving the rear axle only, turn the actuating knob so that it is aligned with the word free stamped on the retainer cap. This will disengage the clutch teeth and thus unlock the wheel hub from the axle shaft. The wheel will now turn free on the axle. **Be certain that the transfer case is** shifted into 2-wheel drive position before disengaging the lock-out hub assembly.

Do not drive the vehicle with one hub engaged and the other disengaged.

Operation Internal Type Lock Position

When the transfer case is to be

shifted into the position for driving the front axle, the hub lock pointer on the center bar must point to the notch under the word LOCK on the retainer cap. If the clutch teeth do not engage with the knob turned to this position, the clutch teeth are butted and a slight movement of the wheel in either direction will complete the lock. The front axle will now drive the wheel. Do not operate in four-wheel drive with the hubs disengaged.

Free Position

When the transfer case is to be shifted into the position for driving the rear axle only, turn the hub lock pointer on the center bar so it points to the notch under the word FREE on the retainer cap. This will disengage the clutch teeth and thus unlock the wheel hub from the axle shaft The wheel will now turn free on the axle.

Be certain that the transfer case is lifted into 2-wheel drive position before disengaging the hub lock.

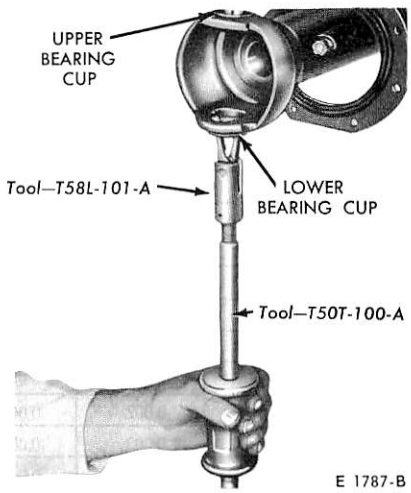

FIG. 5 Removing King Pin Bearing Cup

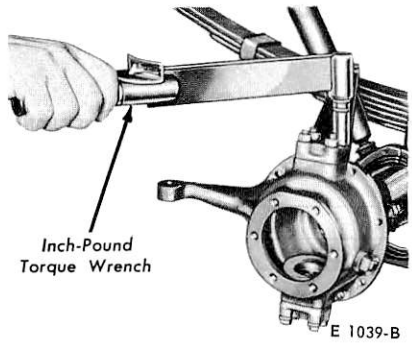

FIG. 6 Checking Steering Knuckle Bearing Preload

REMOVAL AND INSTALLATION

F-250 4 x 4 FRONT AXLE HOUSING

Removal

1. Raise the vehicle on a hoist so that no vehicle weight is supported by the front axle.
2. Remove the hubs, brake backing plates, axle shafts and steering knuckle as given in Front Axle Shaft and Steering Arm.
3. Disconnect both front axle shock absorbers at their lower ends.
4. Disconnect the front axle drive shaft at the pinion flange.
5. Support the front axle on a transmission jack, and then remove the spring clip (U-bolt) nuts and the spring seats.
6. Lower the axle assembly and roll it from under the truck.

Installation

1. Roll the axle under the vehicle and raise it so that the spring clips and spring seats can be installed.
2. Connect the front axle shock absorbers.
3. Connect the front axle drive shaft.
4. Complete the assembly as given in Front Axle Shaft and Steering Knuckle Removal and Installation.

DISASSEMBLY AND ASSEMBLY

PINION, DRIVE GEAR AND DIFFERENTIAL REPAIR

For major repair operations, refer to procedures outlined in Part 15-05, and 15-30, particularly for removing side gears and washers from the differential case. For F-250 vehicles, when doing this operation use Kit T-71T-4205-A (part of the 1971 Essential Kit), TKIT-1971-F or FX and also available separately (See Disassembly and Assembly).

PART 15-33 Front Driving AXLE - Rockwell

Applies to F-600 Only				
COMPONENT INDEX	Page		COMPONENT INDEX	Page
DESCRIPTION	33-01		REMOVAL AND INSTALLATION	33-02
DISASSEMBLY AND OVERHAUL	33-04		SPECIFICATIONS	33-09

DESCRIPTION

The Rockwell-Standard Front Driving Single Reduction Final Drive axle (Fig. 1) employs a heavy duty spiral bevel or hypoid pinion and gear. The differential and gear assembly is mounted on tapered roller bearings. The straddle mounted pinion has two tapered roller bearings in front of the pinion teeth which take the forward and reverse thrust and third bearing behind the pinion teeth to carry the radial load.

Single-Reduction Final Drives are available in a wide range of gear ratios and sizes to cover most operating conditions. The assemblies drive on the coast side.

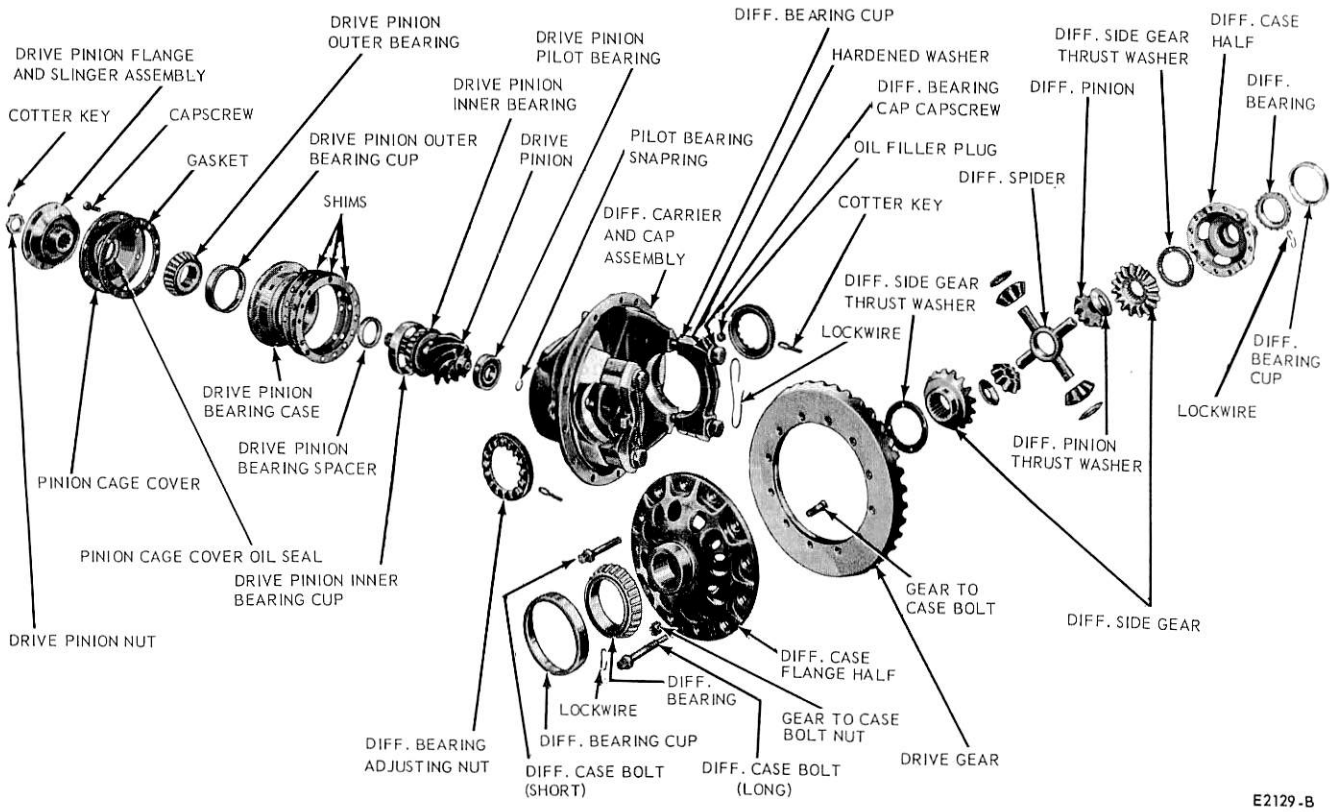

FIG. 1 Front Driving Axle Carrier—Exploded View

REMOVAL AND INSTALLATION

FRONT AXLE SHAFT AND STEERING KNUCKLE

Removal

1. Remove the axle shaft following steps 1 through 13, under Rockwell Four-Wheel Drive Front Axle Removal.
2. Remove the 4 upper bearing cap retaining screws (Figs. 2 and 6).
3. Raise the cap and steering arm and set aside. **Do not drop or lose the shims.**
4. Remove the bearing from the socket and set aside.
5. Remove the four lower bearing cap retaining screws (Figs. 2 and 6).
6. Remove the cap and bearing from the socket and set aside. **Do not drop or lose the shims.**
7. Remove the steering knuckle from the yoke.

Installation

1. Position the knuckle to the yoke.
2. Clean, lubricate and install the upper bearing.
3. Position the shims and bearing cap and steering arm to the knuckle and run in the retaining screws.
4. Clean, lubricate and position the lower bearing, then the shims and cap.
5. Run in the retaining screws.
6. Torque all upper and lower retaining screws to specifications.
7. Using a torque wrench, check the steering knuckle bearing preload.
8. Adjust the shim thickness at the bearing caps as required to bring the preload to specifications.

ROCKWELL FOUR-WHEEL DRIVE FRONT AXLE

Removal

1. Raise the vehicle and use adequate safety stands.
2. Remove the plug from the bottom of the axle housing and drain the lubricant. Replace the plug.
3. Disconnect the driveshaft at the pinion shaft.
4. Remove one front wheel from the brake drum and hub assembly.
5. Remove the outer hub cap retaining screws and remove the cap.
6. Remove the retaining lock ring (Fig. 3).
7. Remove the retaining screws and remove the splined drive plate.
8. Bend the tab of the lockwasher from the locknut and remove the locknut (Fig. 4).
9. Remove the lockwasher and **discard it, and remove the adjusting nut.**
10. Remove the drum and hub assembly from the axle spindle.
11. Remove the brake backing plate retaining screws and carefully lift out the backing plate and wire it up out of the way.
12. Remove the spindle positioning screw and remove the spindle (Fig. 5).
13. Remove the axle shaft from the housing (Fig. 6).
14. Repeat step 4 through 13 to remove the opposite axle shaft.
15. Remove the carrier to housing stud nuts and washers. Loosen two top nuts and leave on studs to prevent carrier from falling.
16. Break carrier loose from axle housing with rawhide mallet. A roller jack should be positioned and fastened to the carrier at this stage.
17. Remove the top nuts and washers and work the carrier free. A small pinch bar may be used to straighten the carrier in the housing bore. However, the end must be rounded to prevent indenting the carrier flange. A roller jack may be used to facilitate removal of the carrier.
18. Place the carrier in repair stand LRE-1730-A or other suitable holding fixture.
19. Prior to disassembly inspect the parts for defects, rotate the gears to test for roughness, and make pattern and backlash checks as a guide to any needed parts replacement. If the gears are not being replaced, the established backlash should be used at reassembly.

Installation

1. Remove all traces of old gasket material from the carrier and housing surfaces; then position a new gasket over the housing mounting studs.
2. Using a roller jack, ease the carrier into position in the housing bore.
3. Position two washers and run two nuts part way on to the studs to hold the carrier; then square up the carrier and align it properly with the housing.
4. Install the housing stud nuts and torque them to specifications.
5. Install one axle shaft in the housing (Fig. 6).
6. Install the spindle and secure it with the positioning screw (Fig. 4).
7. Position the brake backing plate, install the retaining screws and torque to specifications.
8. Carefully position the drum and hub assembly on the axle spindle, and run up the adjusting nut.
9. Using the adjusting nut make the wheel bearing adjustment (Refer to Part 11-12, Adjustments). Position a new lockwasher against the adjusting nut and apply a film of oil to the outer face of the lockwasher.
10. Run the lock nut against the lockwasher and torque it to specifications.
11. Bend one tab of the lockwasher over the adjusting nut.
12. Bend one tab of the lockwasher (in the opposite direction) over the lock nut (Fig. 4). **Use a blunt tool in steps 11 and 12 to avoid making any chips which could cause bearing damage.**
13. Apply Silastic Sealer to the front and rear mounting faces of the splined drive plate, position the drive plate and install the plate retaining screws and torque them to specifications.
14. Install the retaining lock ring (Fig. 3).
15. Position the outer hub cap and install the retaining screws and torque them to specifications.
16. Install the front wheel and torque the nuts to specifications.
17. Connect the drive shaft at the pinion shaft.
18. Repeat steps 5 through 16 for the appropriate axle shaft assembly.
19. Make sure that the housing drain plug has been installed and properly torque.
20. Fill the axle housing with the correct grade and quantity of lubricant.
21. Lower the vehicle.

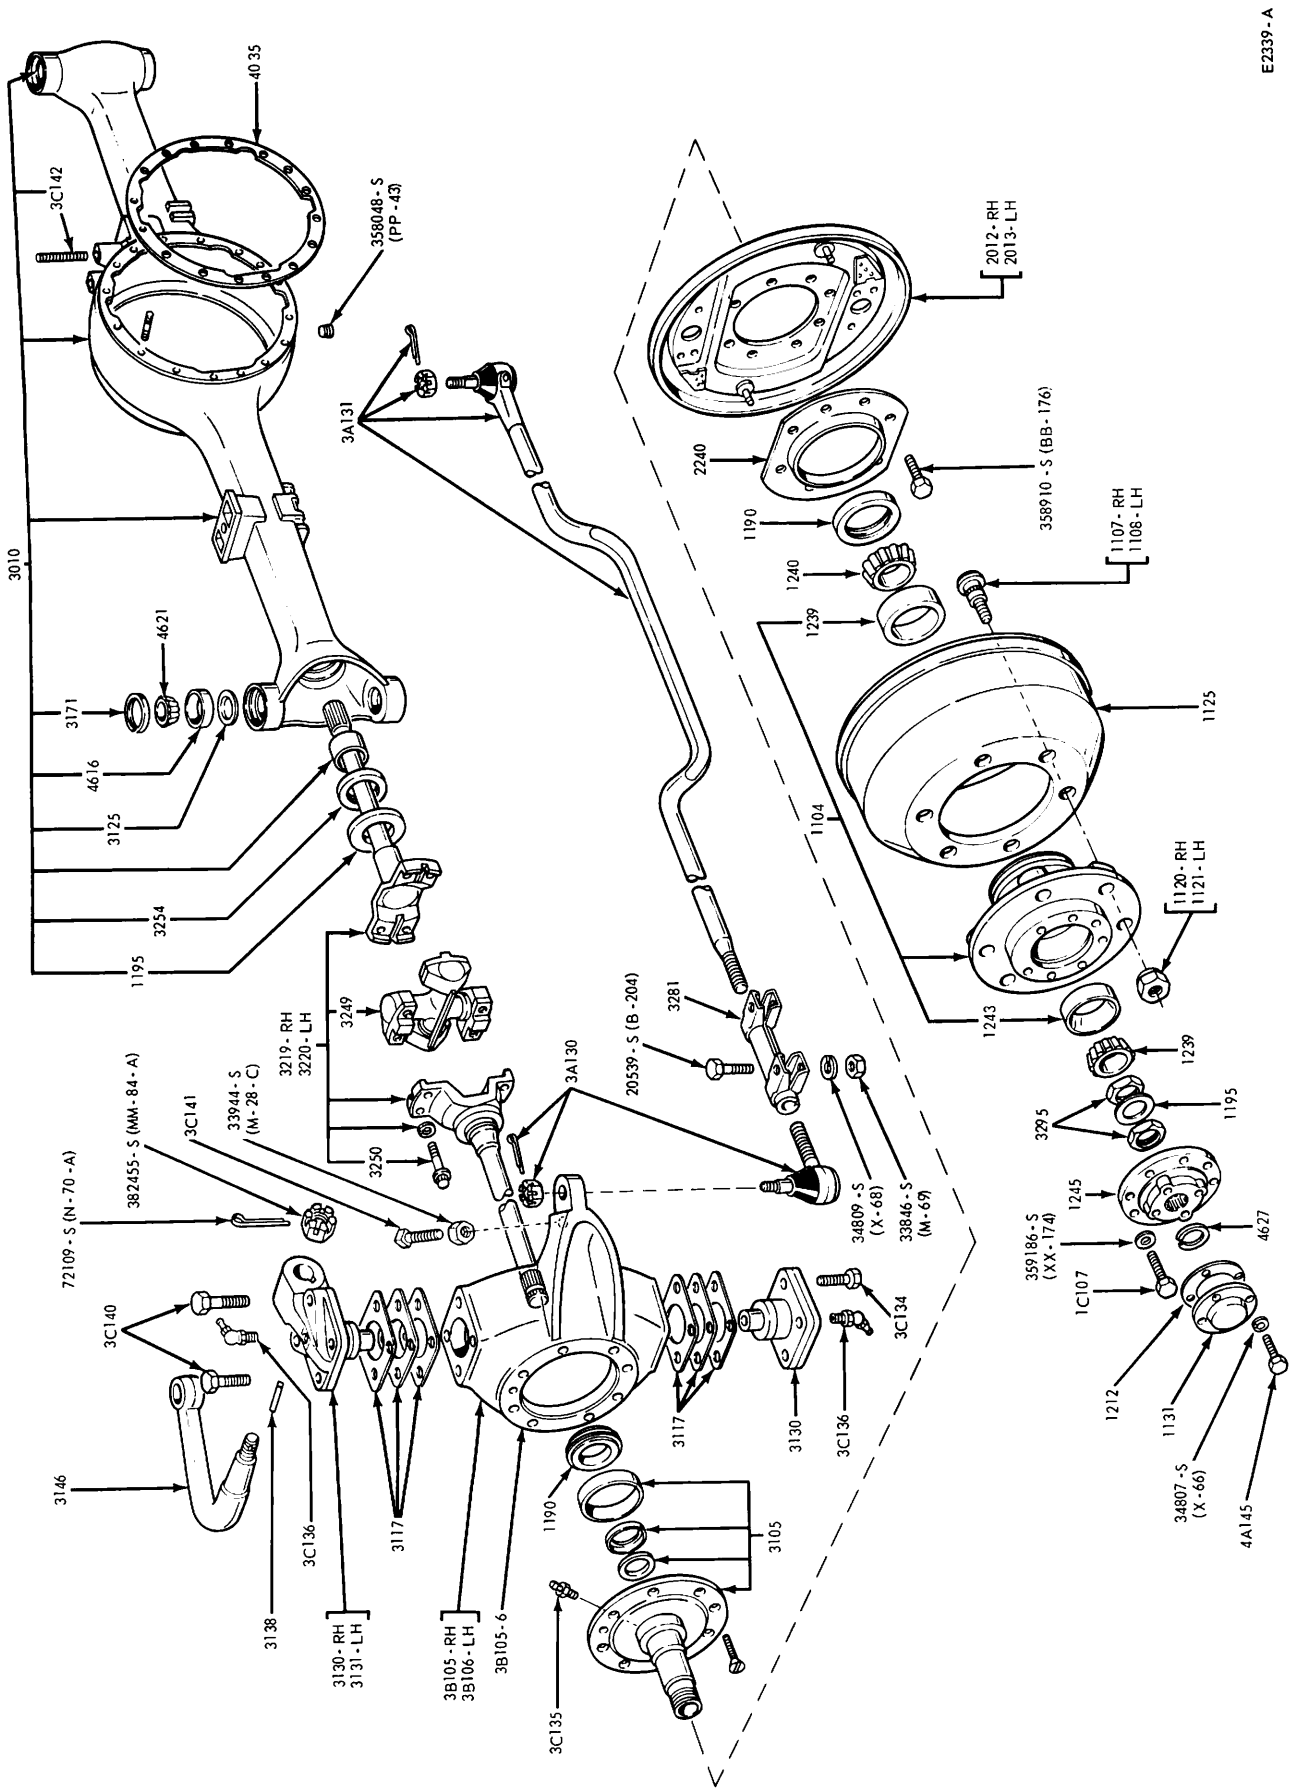

FIG. 2 Front Driving Axle Assembly—Exploded View

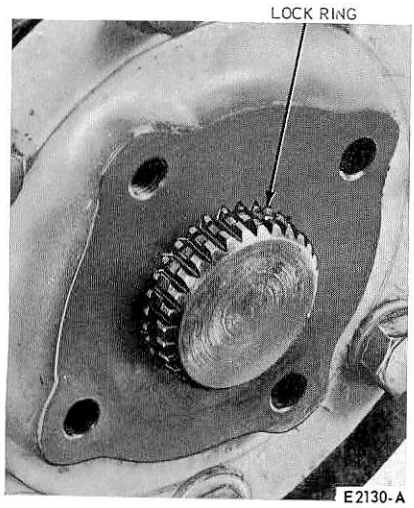

FIG. 3 Access to Lock Ring

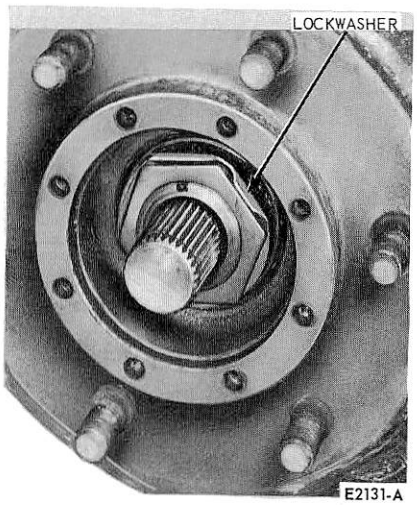

FIG. 4 Locknut and Washer Assembled

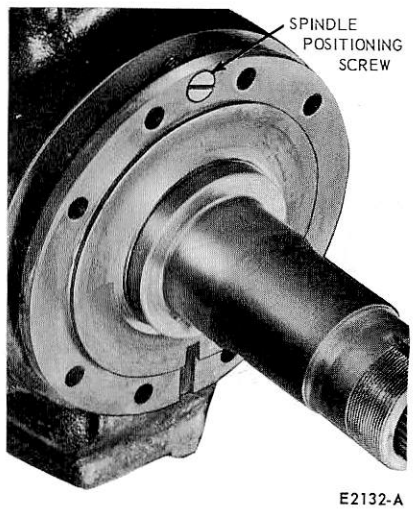

FIG. 5 Spindle in Position

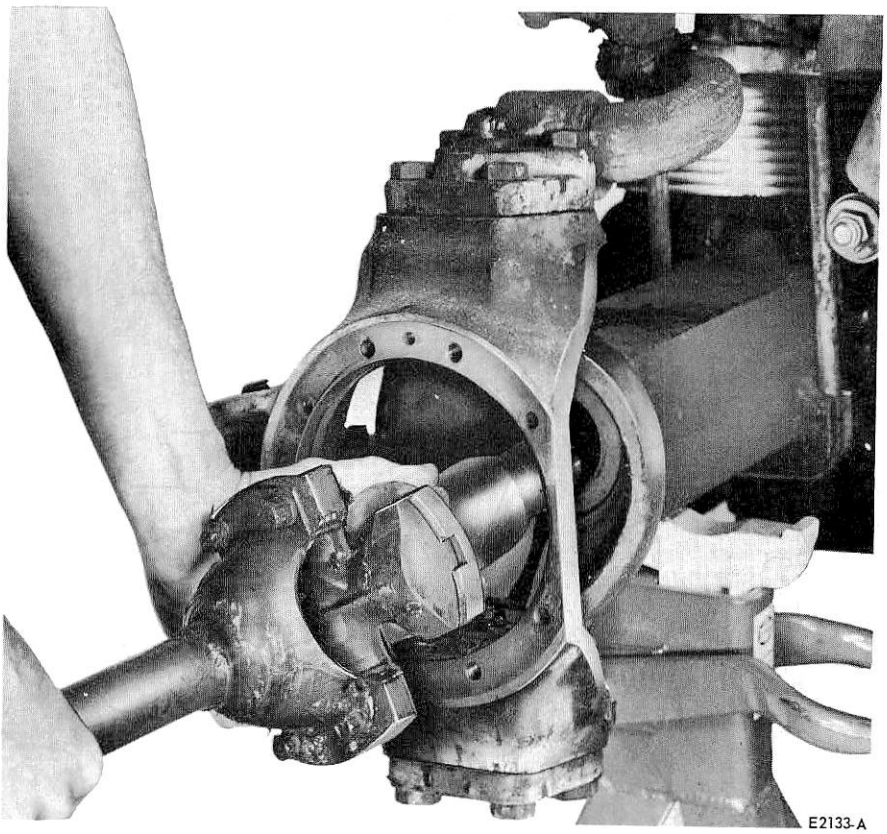

FIG. 6 Axle Removal

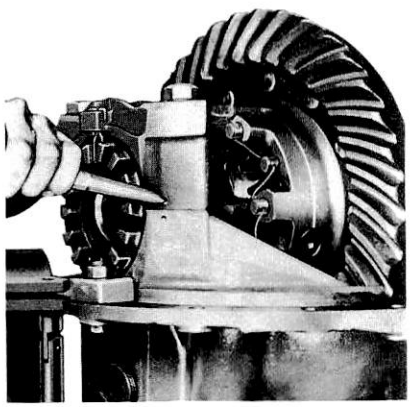
DISASSEMBLY AND ASSEMBLY

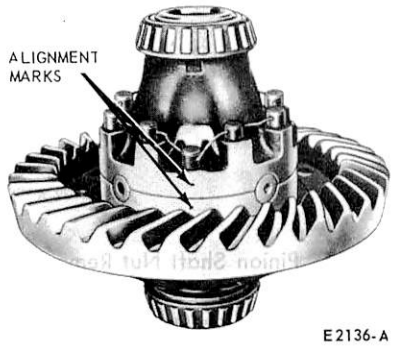
DISASSEMBLY

1. Center punch one differential carrier leg and bearing cap to identify for properly reassembling (Fig. 7).
2. Cut lock wire. Remove cap screws and adjusting nut locks.
3. Remove bearing cap stud nuts or cap screws, bearing caps and adjusting nuts.
4. Lift out differential and gear assembly.
5. If original identification marks are not clear, mark differential case halves with a punch or chisel for correct alignment on reassembling (Fig. 8).
6. Cut lock wire, remove bolts and separate case halves.
7. Remove spider, pinions, side gears and thrust washers.
8. If necessary, remove rivets and separate gear and case.
9. Carefully center punch rivets in center of head.
10. Use a drill 1/32 inch smaller than body of rivet to drill through head (Fig. 9).
11. Press out rivets. **Do not attempt to use a chisel to remove the rivets as this will elongate the flange holes.**
12. If necessary to replace differential bearings, remove with a suitable puller (Fig. 10).
13. Hold flange or yoke with Tool T57T-4851-B and remove pinion shaft nut washer and cage (Fig. 11).
14. Remove flange or yoke with a puller T65L-4851-A (Fig. 12). **Driving the flange off will cause runout.**
15. Remove pinion cage stud nuts or cap screws.



E2135-A

FIG. 7 Bearing Cap Identification



E2136-A

FIG. 8 Alignment of Differential Sections

16. Remove bearing cover and oil seal assembly.
17. Remove bearing cage. Original may have puller holes (Fig. 13).

The use of a pinch bar will damage the shims. Driving pinion from inner end with a drift will damage the bearing lock ring groove.

Wire shim pack together to facilitate adjustment on reassembling.

18. To disassemble the pinion and cage assembly tap shaft out of cage with soft mallet or press shaft from cage.
19. Remove outer bearing from cage. Remove spacer or spacer combination from pinion shaft.
20. If necessary to replace rear thrust bearing or radial bearing, remove with suitable puller (Fig. 14).
21. Remove oil seal assembly from bearing cover.

ASSEMBLY

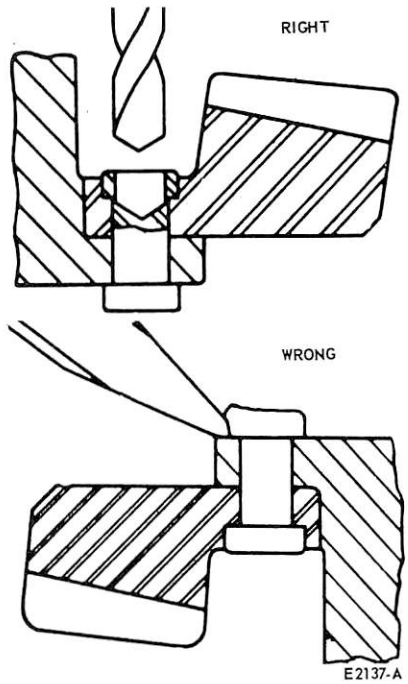
Prior to performing any assembly steps important precautions should be taken.

Parts having ground and polished surfaces such as gears, bearings, shafts and collars, should be cleaned in a suitable solvent such as kerosene or diesel fuel oil.

Gasoline should be avoided.

Do NOT clean these parts in a hot solution tank or with water and alkaline solutions such as sodium hydroxide, orthosilicates or phosphates.

Steam cleaning assembled drive units after they have been removed from the housing is not recommended. When this method of cleaning is used, water is trapped in the cored passage of the castings and in the close clearances between parts as well as on the parts. This can lead to corrosion (rust) of critical parts of the assembly and the possibility of circulating rust particles



E2137-A

FIG. 9 Rivet Removal

in the lubricant. Premature failure of bearings, gears and other parts can be caused by this practice. Assembled drive units cannot be properly cleaned by steam cleaning, dipping or slushing. Complete drive unit disassembly is a necessary requisite to thorough cleaning.

Rough parts such as differential carrier castings, cast brackets and some brake parts may be cleaned in hot solution tanks with mild alkali solutions providing these parts are not ground or polished. The parts should remain in the tank long enough to be thoroughly cleaned and heated through. This will aid the evaporation of the rinse water. The parts should be thoroughly rinsed after cleaning to remove all traces of alkali.

Exercise care to avoid skin rashes and inhalation of vapors when using alkali cleaners.

Completely assembled axles, torque dividers and transfer cases may be steam cleaned on the outside only, to facilitate initial removal and disassembly, providing all openings are closed. Breathers, vented shift units, and all other openings should be tightly covered or closed to prevent the possibility of water entering the assembly.

Parts should be thoroughly dried immediately after cleaning. Use soft,

clean, lintless absorbent paper towels or wiping rags free of abrasive material, such as lapping compound, metal filings or contaminated oil. Bearings should never be dried by spinning with compressed air.

Parts that have been cleaned, dried, inspected and are to be immediately reassembled should be coated with light oil to prevent corrosion. If these parts are to be stored for any length of time, they should be treated with a good rust preventive and wrapped in special paper or other material designed to prevent corrosion.

It is impossible to overstress the importance of careful and thorough inspection of drive unit parts prior to reassembly. Thorough visual inspection for indications of wear or stress, and the replacement of such parts as are necessary will eliminate costly and avoidable drive unit failure.

Inspect all bearings, cups and cones, including those not removed from parts of the drive unit, and replace if rollers or cups are worn, pitted or damaged in any way. Remove parts needing replacement with a suitable puller or in a press with sleeves. Avoid the use of drifts and hammers. They may easily mutilate or distort component parts.

Inspect hypoid gears for wear or damage. Gears which are worn, ridged, pitted or scored, should be replaced. When necessary to replace either the pinion or gear of hypoid set, the entire gear set should be replaced.

Inspect the differential assembly for pitted, scored or worn thrust surfaces of differential case halves, thrust washers, spider trunnions and differential gears. Thrust washers must be replaced in sets. The use of a combination of old and new washers will result in premature failure.

Check for wear or damage to the differential pinion and side gear teeth. Always replace differential pinions and side gears in sets.

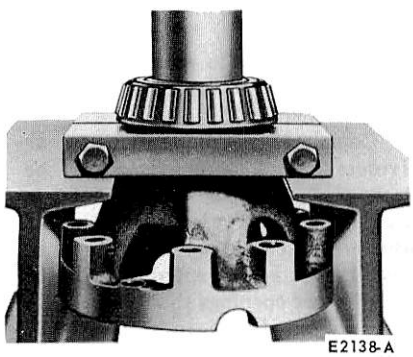


FIG. 10 Bearing Removal

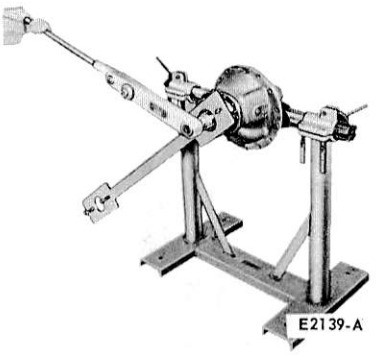

FIG. 11 Pinion Shaft Nut Removal

Inspect axle shafts for signs of torsional fractures or other indication of impending failure.

1. If new cups are to be installed, press firmly against pinion bearing cage shoulders using Tool T53T-4616-C.
2. Lubricate bearings and cups with light machine oil.
3. Press rear thrust and radial bearings firmly against the pinion shoulders with chamfer toward pinion teeth using a suitable sleeve that will bear only on bearing inner race T53T-4621-A (Fig. 15).
4. Install radial bearing lock ring and squeeze ring into pinion shaft groove with pliers.
5. Insert pinion and bearing assembly in pinion cage and position spacer or spacer combination over pinion shaft.
6. Press front bearing firmly against spacer.
7. Rotate cage several revolutions to assure normal bearing contact.
8. While in press under pressure, check bearing preload torque. Wrap soft wire around cage and pull on horizontal line with pound scale (Fig. 16). If a press is not available, the pinion nut may be tightened to the correct torque and preload checked.

For correct pressures and torque for checking pinion bearing preload refer to the Specifications Section in this Part.

If rotating torque is not within 5 to 15 ins-lb, use thinner spacer to increase or thicker spacer to decrease preload.

Example: Assuming pinion cage diameter to be 6 inches, the radius would be 3 inches and with 5 pounds pull woul equal 15 ins-lb preload torque.

9. Press flange or yoke against forward bearing and install washer and pinion shaft nut.
10. Place pinion and cage assembly over carrier studs, hold flange and tighten pinion shaft nut to the correct torque. The flange must be held with a suitable tool or fixture to tighten nut (Fig. 11).
11. Recheck pinion bearing preload torque. If rotating torque is not within 5 to 15 ins-lb, repeat the foregoing procedure.
12. Hold flange and remove pinion shaft nut and flange.
13. Lubricate pinion shaft oil seal and cover outer edge of seal body with a non-hardening sealing compound. Press seal against cover shoulder with seal driver (Fig. 17).
14. Install new gasket and bearing cover.
15. Press flange against forward bearing and install washer and pinion shaft nut.
16. Tighten to the correct torque and install cotter key.

Do not back off nut to align cotter key holes.

17. Install correct shim pack. **Locate thin shims on both sides for maximum sealing ability.**
18. Position pinion and cage assembly over studs and tap into position with soft mallet.
19. Install lock washers and stud nuts or cap screws. Torque to specifications.
20. If it was removed, position the gear to the case.

Differential case and gear bolts are available for service replacement of rivets. The use of bolts greatly facilitates servicing these units in the field and eliminates the need for special equipment necessary to correctly cold upset rivets. Consult chart for service bolt instruction shown with the torque chart (Specifications in this Part).

21. Lubricate differential case inner walls and all component parts with axle lubricant.
22. Position thrust washer and side gear in bevel gear and case half assembly.
23. Place spider with pinions and thrust washers in position.
24. Install component side gear and thrust washer.
25. Align mating marks, position component case half and draw

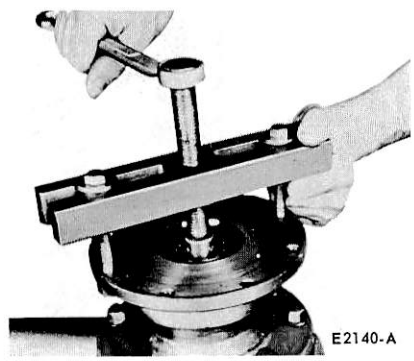

FIG. 12 Yoke Removal

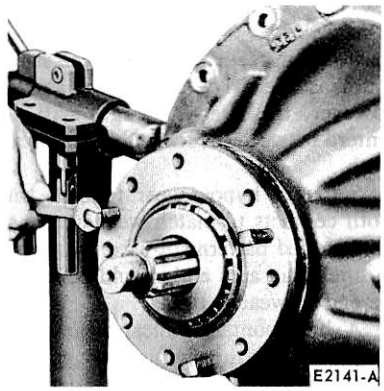

FIG. 13 Bearing Cage Removal

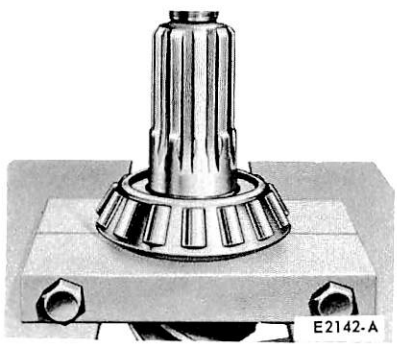

FIG. 14 Bearing Removal

FIG. 15 Rear Bearing Installation

assembly together with four bolts or cap screws equally spaced (Fig. 18).

26. Check assembly for free rotation of differential gears and correct if necessary.
27. Install remaining bolts and cap screws, tighten to the correct torque and lock wire.
28. If bearings are to be replaced, press squarely and firmly on differential case halves Tool T56T-4242-A.
29. Temporarily install the bearing cups, threaded adjusting rings where employed and bearing caps. Tighten the cap screws to the proper torque.
30. The bearing cups must be of a hand push fit in the bores, otherwise the bores must be reworked with a scraper or some emery cloth until a hand push fit is obtained. Use a blued bearing cup as a gauge and check the fits as work progresses. Once the cups fit properly, remove the bearing caps (Fig. 19).
31. After checking related parts, coat the differential bearing cones and cups with specified rear axle lubricant.
32. Place the bearing cups over the assembled differential bearing cones, then position the differential assembly in the carrier.
33. Insert bearing adjusting nuts and turn handtight against bearing cups.
34. Install bearing caps in the correct location as marked and tap lightly into position.
35. **If bearing caps do not position properly, adjusting nuts may be cross threaded. Remove caps and reposition the adjusting nuts. Forcing caps into position will result in irrepairable damage to the carrier housing or bearing caps.**
36. Install flat washers where used and stud nuts or cap screws. Tighten stud nuts or cap screws to specifications.
37. Using dial indicator at back-face of gear, loosen the bearing adjusting nut on **the side opposite gear only** sufficient to notice end play on the indicator.
38. Tighten the same adjusting nut only sufficient to obtain .000 end play.
39. Check gear for runout. If runout exceeds .008 inch, remove differential and check for cause.
40. Tighten adjusting nuts **one notch each** from .000 end play to preload differential bearings.
41. If the drive gear is not going to be replaced, the established backlash recorded before disassembly should be used. For new gears the new backlash should be initially set at .010 inch. Adjust backlash by moving the gear only. This is done by backing off one adjust ring and

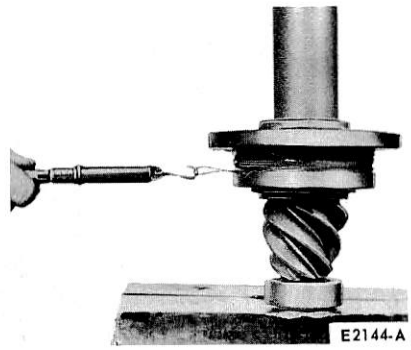

FIG. 16 Checking Bearing Pre-Load Torque

FIG. 17 Seal Installation

FIG. 18 Case-to-Gear Alignment

FIG. 19 Fitting Bearing Cups

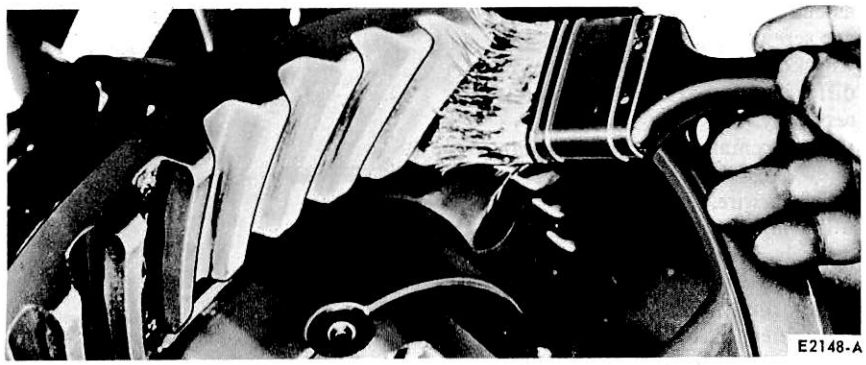

FIG. 20 Application for Pattern Check

advancing the opposite ring the same amount.

42. Apply oiled red lead lightly to the hypoid gear teeth. When the pinion is rotated, the red lead is squeezed away by the contact of the teeth, leaving bare areas the exact size, shape and location of the contacts (Fig. 20).
43. Sharper impressions may be obtained by applying a small amount of resistance to the gear with a flat steel bar and using a wrench to rotate the pinion. When making adjustments, check the drive side of the gear teeth. Coast side should be automatically correct when drive side is correct. As a rule, coating about twelve teeth is sufficient for checking purposes.
44. After obtaining a satisfactory tooth contact, especially in relation to the top and bottom of the tooth, the backlash can be altered within the limits of .005 inch-.015 inch to obtain a better contact position relative to the length of the tooth.
45. A high backlash setting can be used to keep the contact from starting too close to the toe, and a low backlash setting can be used to keep the contact from starting too far away from the toe.
46. After correct tooth contact has been established, install adjusting nut locks and cap screws. Tighten cap screws and lock wire to bearing cap screws.

With gears unloaded and with adjustments properly made (pinion at correct depth and backlash set at .010 inch) the contacts shown in the left view of Fig. 21 will be procured. The area of contact favors the toe and is centered between the top and bottom of the tooth.

The hand rolled pattern shown at left (gears unloaded), will result in a pattern centered in the length of the tooth when the gears are under load shown at right. The loaded pattern will be almost full length and the top of pattern will approach the top of the gear tooth.

With gears loaded the pattern on the coast side of teeth will appear the same width as the drive side shown above; however, the over-all length will be centerd between the toe and heel of gear tooth.

Set used hypoid gear to have the tooth contacts to match wear patterns. Hand rolled patterns of used gears will be smaller in area and should be at the toe end of wear patterns.

A high contact indicates pinion is too far out. Set the pinion to the correct depth by removing shims under the pinion cage. Slight outward movement of hypoid gear may be necessary to maintain correct backlash (Fig. 22).

A low contact indicates pinion is too deep. Set the pinion to the correct depth by adding shims under the pinion cage. Slight inward movement of the hypoid gear may be necessary to maintain correct backlash (Fig. 22).

PART 15-40 Traction-Lok Limited Slip Differential - Ford

Applies to Bronco, F-100 (4 x 2) and F-100 (4 x 4) Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION	40-01	DISASSEMBLY AND OVERHAUL	40-02

The Traction-Lok differential (Fig. 1) employs a multiple disc clutch to control differential action, Shim(s), which control side gear mounting distance, four steel, four friction and one composite plate (steel on one side and friction material on the other) stacked on a clutch hub, and four ear guides are housed in the differential cover. Located in the differential case between the side gears is a one-piece pre-load plate and block and four calibrated pre-load springs, which apply an intial force to the clutch pack. Additional clutch capacity is derived from the side gear thrust loads. The four friction plates are splined to the clutch hub which in turn is splined to the left axle shaft, and the eared steel plates are dogged to the case; thus, the clutch is always engaged.

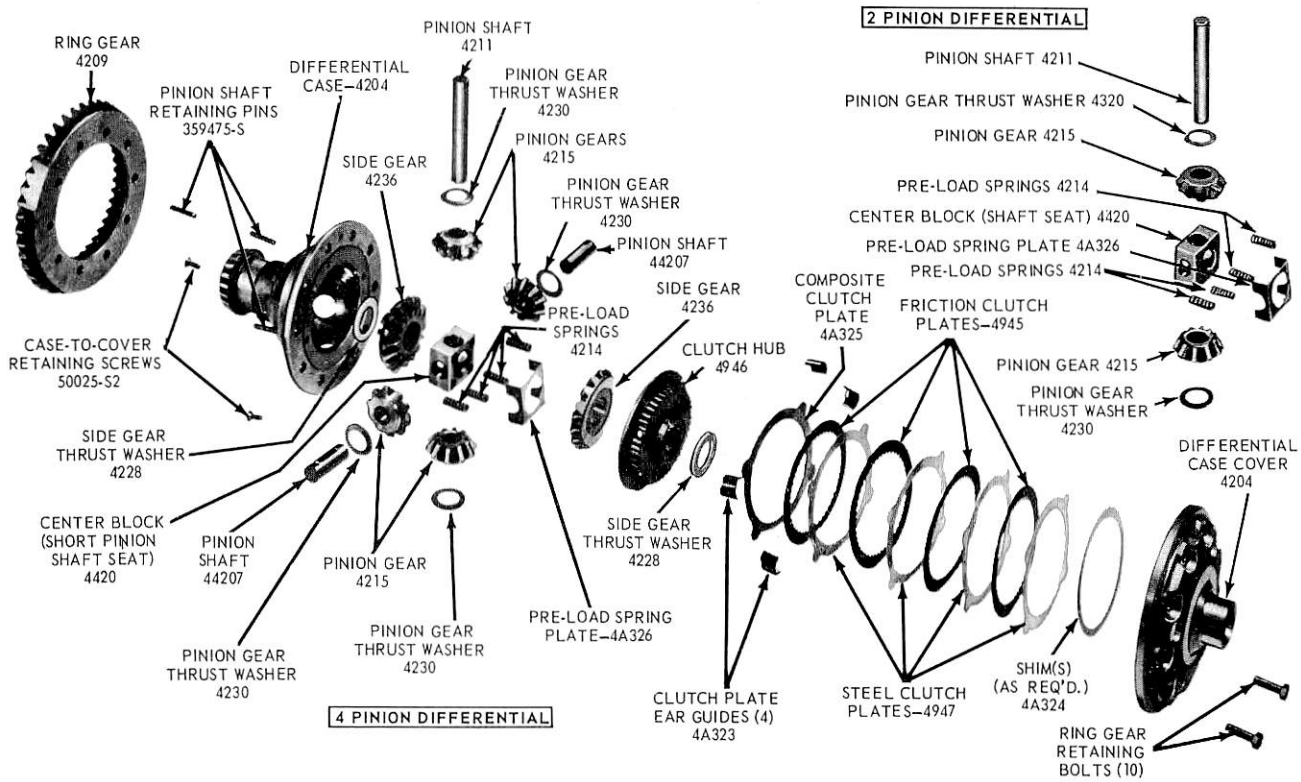

FIG. 1 Ford Traction-Lok Differential—Disassembled

ADJUSTMENTS

No in-vehicle adjustments are possible on this unit. Refer to the applicable axle section for Adjustments to the axle in which it is installed.

REMOVAL AND INSTALLATION

Refer to Part 15-10 for removal of this differential which is removed and installed in the same manner as a conventional differential.

DISASSEMBLY AND ASSEMBLY

Removal and Installation procedures for the differential (removable carrier) are the same as the conventional Ford axle, except in the area of the differential case disassembly and assembly which follows:

DISASSEMBLY

1. Remove ten bolts and flat washers securing the ring gear to the differential case assembly. The ring gear must be removed in order to separate the case halves.
2. Remove the ring gear by tapping the gear with a soft hammer or press the gear from the case.
3. Place the differential case in a press to load the case at the bearing journals so that the pre-load of the springs is overcome (approx. 1,500 lbs). **If a press is not available, two 7/16 inch bolts and nuts can be used in the ring gear mounting holes (one on each side) to compress the case halves together and overcome preload spring tension.** Then, while the case is still under pressure, loosen the two Allen or Phillips head screws which hold the case halves together until one or two threads of the screws remain engaged. Remove the case assembly from the press. Tap on the cover to spring it loose; then, remove both screws.
4. With the cover facing down, lift off the case. Remove the pre-load spring plate and four pre-load springs.
5. From the cover remove the side gear, four clutch plate ear guides, clutch hub, friction and steel clutch plates and shim(s).
6. With a suitable drift, drive out the pinion shaft lock pins from the case.
7. With a brass drift, drive out the long pinion shaft from the case. Drive from the end opposite the lock pin hole.
8. Remove the two short pinion shafts using a drift, driving each shaft from the center outward. Lift out the center block, then remove the pinion gears, thrust washers and side gear and thrust washer.
9. If the differential bearings are removed, the bearings can be installed in one of the following ways:
   a. With the differential case and cover completely assembled.
   b. On the case or cover when disassembled. However, when pressing the bearing on the cover, a block of wood or fiber must be used as shown in Fig. 2 in order to avoid damage to the cover.

ASSEMBLY

1. **Lubricate all parts with C9AZ-19580-A lubricant during assembly.**
2. Mount the differential case in a soft jaw vise and place a side gear thrust washer and side gear in the counterbore of the case.
3. Install the pinion thrust washers and place the pinion gears on the side gear aligning the holes in the washers and gears with the holes in the case.
4. Install the center block so that the shaft holes are aligned with the holes in the pinion gears and case. **The center block has two machined sides and two rough sides.**
5. With a brass drift, drive in the long pinion shaft from the outside of the case aligning the lock pin holes in the shaft with the holes in the case. **The center block should be positioned so the long shaft is driven through the rough side and short shafts driven through the machined side (Fig. 3).**
6. With a suitable drift, install the shaft lock pins. Make sure the pinion and side gears move freely.
7. Place the four pre-load springs in the holes provided in the center block.
8. Position the pre-load plate over the four springs, making sure the springs are properly seated. The pre-load plate straddles the center block over its narrower or machined width.
9. Mount the differential cover in a soft jawed vise or holding fixture.
10. Insert shim(s) of 0.050 total thickness in the cover cavity.
11. Install the composite plate (friction material on one side and steel on the opposite) on the back side of the clutch hub with the friction material against the hub; next, install a friction plate, then steel, friction, steel, friction, steel, friction, and lastly a steel plate (Figures 1 and 4). **When new clutch plates are used, soak the plates in Ford Hypoid Lubricant (C9AZ-19580-A), for approximately 30 minutes before installation.**
12. Place the clutch hub with the clutch plates into the clutch gear cavities in the differential cover. Make sure that the splines on the last friction plate are engaged on the hub.
13. Obtain locally a 5/8 inch x 2 1/2 inch or 9/16 inch x 2 1/2 inch bolt, nut and two 1 1/2 inch outside diameter flat washers approx. 1/8 inch in thickness. These parts are required to compress the clutch pack in order to obtain the proper shim selection. Install a flat washer on the bolt, and place the bolt through the clutch hub. Hold the bolt in position and turn the cover over. Place a flat washer on the bolt and then install the nut. Be sure the washers are centered, and torque the nut 10 or 15 ft-lbs (Fig. 5).
14. Place the shim template tool (T68P-4946-A) in the clutch hub (Fig. 21). Some clearance should be observed between the shim tool and the cover-to-case mating surface. **Using a feeler gauge, determine the exact amount of clearance.** The shim pack thickness chart which will indicate the correct amount of shim(s) to subtract from the 0.050 shim originally installed. **In order to correctly select the proper shim(s), the shim template tool and the chart must be used. Refer to Specifications.**
15. After the proper shim selection is determined, remove the bolt, nut and flat washers. If it is necessary to revise the shim thickness, remove the clutch hub and clutch plates.

16. Install the selected shim(s) in the cover cavity, re-install the components as outlined in Steps 11 and 12.
17. Install the four steel clutch ear guides and side gear.
18. Place both assemblies in a press, and press the two halves together; then, insert the two Allen head or Phillips head screws, and tighten evenly until tight. If a press is not available, any two stock bolts and nuts may be used opposite each other in the ring gear retaining holes to compress both halves.
19. Install the ring gear and ring gear bolts and washers. Tighten evenly and alternately across the diameter of the ring gear. Torque the bolts to 65-80 ft-lbs.
20. Prior to installation of the torque sensitive locking differential into a vehicle, a bench torque check must be made. With currently released locker tools, check the torque required to rotate one side gear while the other is held stationary. The initial breakaway torque may exceed 250 ft-lbs. The rotating torque required to keep the side gear turning with new clutch plates is 100 to 250 ft-lbs. With reused clutch plates, the minimum torque required is 40 ft-lbs. (The torque may fluctuate 10-40 ft-lbs).

DESCRIPTION

DETROIT AUTOMOTIVE PRODUCTS NO SPIN LOCKING DIFFERENTIAL

The No Spin unit is a true locking differential, basically a system of dog-clutches and cams, containing no power-averaging gearing as in a conventional differential. When moving in a straight line, backward or forward, both wheels must turn, because they are positively locked together at the axle shafts by dog-clutches. This is in contrast to the limited slip type differential, which contains more or less conventional differential gearing with a system of clutches acting as retarders on the normal differential action. In other words, there is no breakaway torque at which the No Spin will release, as in limited slip type differentials.

In order to get differential action, which basically is allowing one wheel to run faster or further than the other while the vehicle is turning, a system of cams disengages the dog clutch on the side that is turning in the greatest circle. Immediately that the wheels resume straight line travel, the dog clutches again engage, locking the axle shafts together at the differential case.

It should be noted that in a No Spin installation, the inside wheel always turns at ring gear speed, because of the direct mechanical lock to the differential case. This is not true of a geared differential system, which averages the power transmitted to the wheels, so that the inside wheel may actually turn slower than the ring gear, while the outside wheel turns faster.

Figure 1 is an exploded view of the standard type No Spin differential.

Figure 2 is a disassembled view of the various No Spin assemblies which can be installed in all Ford trucks. On Ford F-100 and F-250 trucks, the silent type No Spin is usually furnished with a special differential case, whereas the standard type used on the larger trucks drops into the existing case.

Figure 3 shows the relative position of the No Spin unit when installed in the typical axle.

Figure 4 shows the positions of the various parts when the wheels are moving straight ahead and when making right and left turns.

As can be seen in Fig. 4 the basic difference between the silent type and the standard type is the added hold out ring interposed between the driven clutch and the spider, or driving member. When the outside wheel is unlocked, while the vehicle is turning, a normal ratcheting action takes place as the driven clutch on that side walks around the spider. In the standard type, this ratcheting is audible as a clicking noise. The noise is due to the in-and-out motion of the driven clutch teeth and the cam surfaces. The holdout ring, in the silent types, acts to limit the in-and-out motion until the exact instant that the wheels resume straight-ahead travel. As can be seen in Fig. 2, the holdout ring is a simple device. It turns with the spider, but has some lost motion due to the wide slot which indexes it to the spider. When a wheel begins to over run, so that its driven clutch moves outward by cam action, the holdout ring, riding the same center cam, also moves outward and then turns slightly, due to the lost motion built into it at the indexing slot. This action takes up the slack in the mechanism and prevents the in-and-out hunting action of the cam and clutch teeth which produces noise. As soon as the over-running wheel slows down, the hold-out ring reverses its movement, due to the wide indexing slot, and moves inward on the center cam, along with the driven clutch of that wheel. This action is instantaneous.

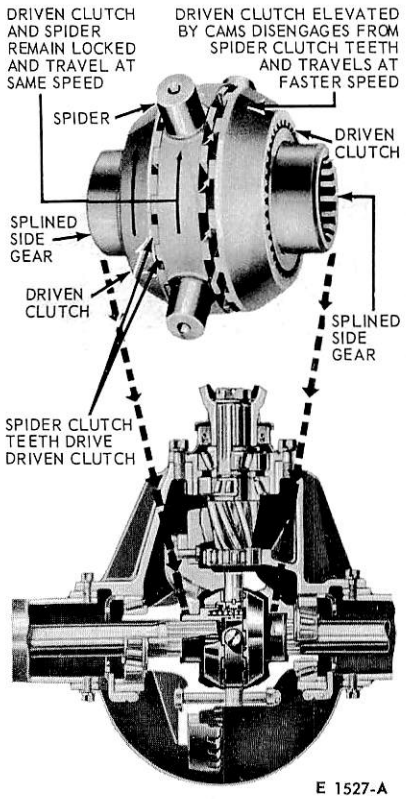

FIG. 3 No Spin Differential Installed

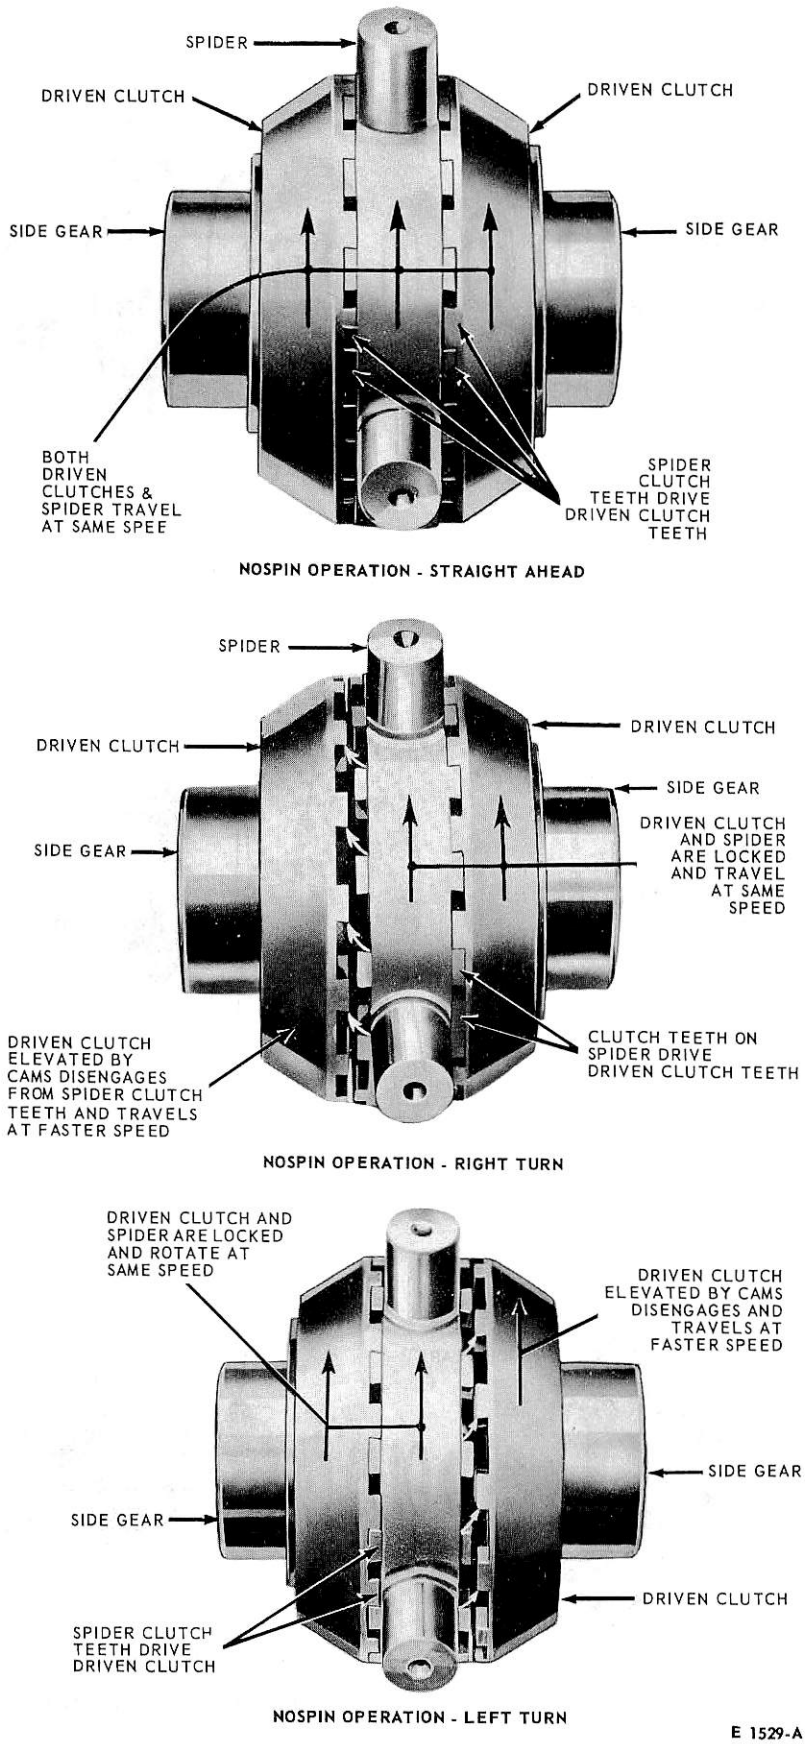

FIG. 4 No Spin Operation

ADJUSTMENTS

No in-vehicle adjustments are possible on this unit. Refer to the applicable axle section for adjustments to the axle in which it is installed.

REMOVAL AND INSTALLATION

Refer to the applicable axle instructions for removal of this differential which is removed and replaced exactly the same as a standard differential.

DISASSEMBLY AND ASSEMBLY

The No Spin locking differential assembly is removed and installed in exactly the same manner as the conventional differential assembly.

DISASSEMBLY

Repairs to the standard No Spin differential will not require removal of the ring gear or differential bearings, since the unit drops into the existing differential case. Certain precautions are necessary for the differential case, because it is spring-loaded. Refer to Removal From the Differential Case, below.

Repairs to the silent type No Spin differential used in the F-100 and F-250 axles require removal of the ring gear, since the special differential case furnished with the unit is assembled by means of the ring gear attaching bolts.

Removal Of Differential Unit From Differential Case

Before removing either the standard or the silent No Spin unit from the differential case, make up a long bolt and nut assembly similar to the one shown in Fig. 5, and clamp the unit together. This will prevent the spring loaded No Spin unit from flying apart when taken from the differential case.

1. Mark the mating halves of the differential case with a center punch so they can be installed in their original position.
2. Remove the ring gear attaching bolts and separate the two case halves.
3. Remove the No Spin unit from the case and carefully release the spring tension by unscrewing the nut and bolt assembly (Fig. 5).

INSPECTION

1. Thoroughly wash all parts in a suitable solvent and dry with compressed air.
2. Inspect the splines on the side gears and clutch members. Remove any burrs or small chipped edges with a stone or electric burr grinder. If large sections of the spline are broken away, replace the part. Check the side gear hubs for fractures.
3. Check the spring heights. They should be within 1/4 inch of the original in the F-100, F-250, F-and P-350.
4. Check for fractures or chipping of the holdout ring and excessive wear of the cam teeth. A badly worn or chipped holdout ring can cause chipping of clutch teeth.
5. Check the center cam for free movement. It must be free to rotate within the limits of the keys in the spider (Fig. 6). It is not necessary to remove the center cam for inspection. In most of the light series units, the spider or drive member is serviced as an assembly with the center cam. If the spider (drive member) or center cam is damaged, the assembly must be replaced.
6. Check the spring retainer (Fig. 4) for fractured splines or spring seat.
7. Check for failure of the hydrogen weld attaching the cam surface of the driven clutch to the clutch (if the two-piece unit is used). If a weld failure has occurred, it will be possible to rotate the cam ring in the driven clutch by tapping lightly on the cams.

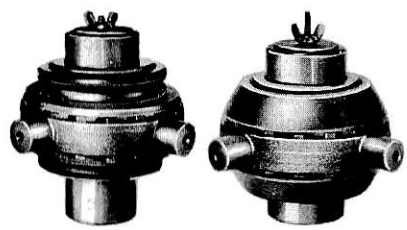

FIG. ASSEMBLY AND DISASSEMBLY CLAMP E 1530-A

FIG. 5 Assembly and Disassembly Clamp—No Spin

8. Inspect the clutch teeth on the spider and driven clutches. Very slight chips can be touched up with a stone. If excessively chipped or rounded, these parts must be replaced. Compare the tooth form with a new part, if available. If a part is replaced due to chipped teeth, always replace the mating part as it may have invisible fractures.
9. Cams on the center cam and driven clutch must not be excessively chipped. A smooth wear pattern up to 50 per cent of the face width is acceptable on the clutch cam and center cam.
10. Check the side gear spline fit on its mating axle shaft. Be sure the splines do not bind.

11. If a case was furnished with the No Spin differential, inspect it according to the standard instructions given in Part 15-01.

ASSEMBLY

Installation of Differential Unit In The Differential Case

1. Assemble the No Spin, being careful to position the spring retainers so that the spring seats inside the cupped section (Fig. 4).
2. Clamp the unit together, using an assembly of bolt, washers and nut similar to Figure 5.
3. Position the No Spin unit in the differential case. Align the punch marks that were made during disassembly to mate the two halves. Install the ring gear and attaching bolts. Torque the attaching bolts to the torque specified for the factory axle which the No Spin replaced.
4. Before installing the No Spin and differential case assembly into the axle carrier, place an axle shaft in each side and rotate. It should be possible to feel the backlash between the clutch teeth (about 5/32 inch). If this backlash cannot be felt, and the side gear is locked solid in the No Spin, remove the unit from the case and check the assembly (Fig. 4).
5. If the correct backlash is present, assemble the differential case into the carrier and follow the instructions in Removal and Installation to complete assembly of the axle involved.
6. When the axle is assembled, fill with the recommended lubricant for the factory-standard axle. **No special lubricant or additive is necessary in the No Spin Installation.**

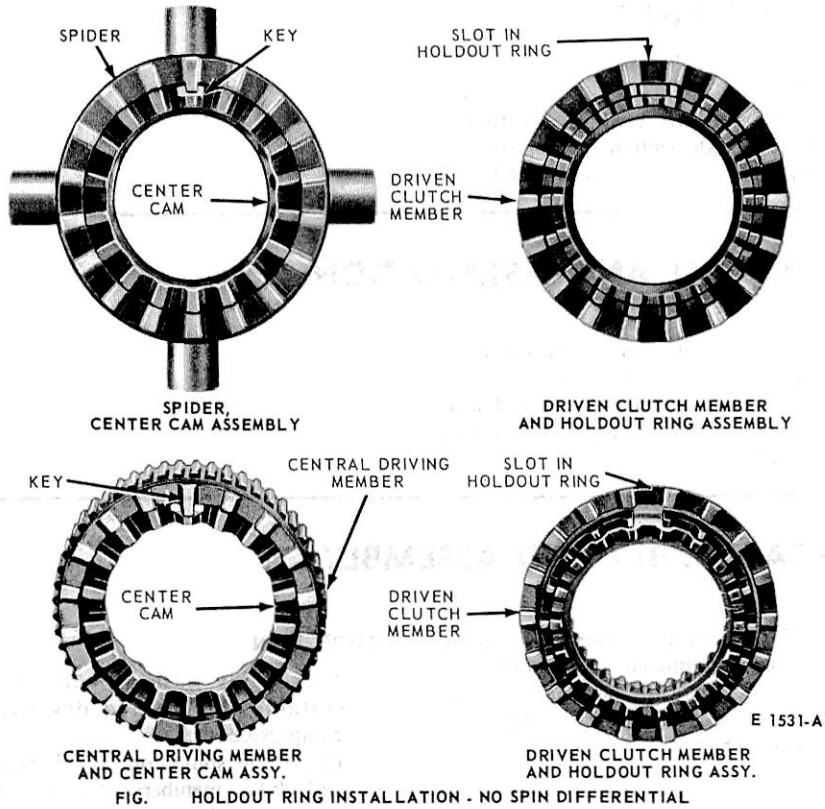

FIG. 6 Holdout Ring Installation—No Spin Differential

PART 15-42 Limited Slip Differential - Dana

Applies to E-300, F-250-350 and P-350

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DESCRIPTION	42-01	REMOVAL AND INSTALLATION	42-03
DISASSEMBLY AND OVERHAUL	42-03		

DESCRIPTION AND OPERATION

DANA LIMITED—SLIP DIFFERENTIAL

The limited-slip Dana Trac-Lok Model 60 (a 2 pinion) axle and the 4 pinion model 70 have a power flow identical to the conventional rear axle, plus a more direct power flow which automatically takes effect as driving conditions demand. This more direct power flow is from the differential case to each axle shaft through clutches.

Figure 1 shows the clutch in a model 60 that connects the differential case to the axle shaft; an identical clutch on the opposite side of the differential connects the differential case to the opposite shaft.

Each clutch plate and disc pack consists of 5 steel plates, set between the case and the side gear ring. Three of the clutch plates, having external lugs, are locked to the differential case by the external lugs. The clutch plate that is installed next to the case is a Belleville spring plate. This spring plate is installed with the concave (dished) side against the case. The remaining clutch discs have internal spline teeth which look to the splined hub on the side gear ring. The side gear ring is, in turn, splined to the axle shaft and acts as a pressure plate against the clutch pack. Since the side gear ring fits against the pinions on the cross shaft (mate shaft), any outward force exerted by the mate shaft and its pinions will press the ring against the clutch pack and thus connect the differential case directly to the axle shaft.

Unlike the cross shafts of the conventional unit the limited-slip differential mate shafts are not rigidly attached to the differential case, nor are they attached to each other. At both ends of the mate shafts there are two flat surfaces so arranged that they form a V which mates with corresponding V shaped surfaces (ramps) cut in the shaft openings of the differential case. The mate shafts are assembled in the case with enough clearance so that when the case tries to rotate the mate shafts and the mate shafts resist rotation, they will be forced to bear against one side of their V ramps. Since the two V ramps of one mate shaft point in a direction opposite to that of the two V ramps of the other mate shaft, the two shafts with their pinions will be forced apart as they resist rotation. This mate shaft movement compresses the clutch pack through the pinion gears and side gear rings.

When the differential case rotates in the opposite direction, the mate shafts will be forced to bear against the opposite side of their V ramps and will again be forced apart to apply against the clutch packs. Therefore, since the ramps are V shaped, the clutches will apply during either forward or reverse operation. Likewise, the clutches will apply whether the power flow is from the differential case to the axle shafts, or from the axle shaft to the differential case.

The amount of compression on the clutch plates will be proportionate to the load applied to the differential case and the resistance to turning offered by each mate shaft. For example, if the vehicle is driven straight ahead and the traction or load on both wheels is equal, both mate shafts will give equal resistance to the rotating differential case and will thus bear against their respective ramps with equal force. This equal movement of the mate shafts will cause them to exert equal pressure against both right and left clutch packs. Both axle shafts will, therefore, be locked directly to the case

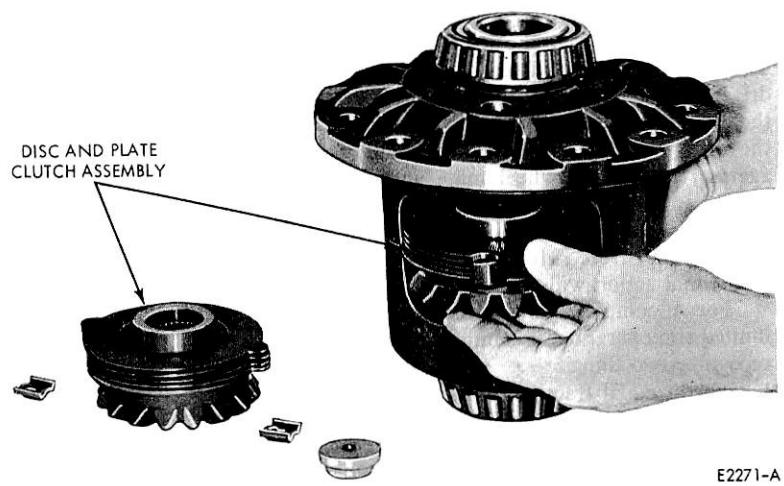

FIG. 1 Limited-Slip Differential (Dana Model 60—Clutch Packs)

with equal force (Fig. 2). Figure 3 shows a cutaway view of a model 70 axle assembly.

Clutch application prevents momentary spinning of one of the wheels when it leaves the road because of a bump, or encounters poor traction because of a slippery road. Under these conditions, even though the traction load is relieved on the one wheel, the acceleration load is simultaneously applied to the differential case as the engine tries to spin the wheel.

When the rear axle is in a turn, the appropriate clutch releases automatically to allow normal differential operation as required. In the straight ahead position, the differential case is driving both wheels and thus applies an equal load against both mate shafts. Since both mate shafts offer resistance to this load, both clutches are applied. On a turn, however, the outside wheel turns faster than the inside wheel. The outside wheel, instead of being driven by the case, now tends to drive the case. With the power thus relieved, the differential case releases its load against the outside wheel mate shaft which, in turn, releases its pressure against the outside wheel clutch pack. With the clutch released, normal differential action will take effect.

For a complete understanding of limited-slip operation, it is important to recognize two things:

1. If with equal traction, both wheels slip, the axle has done all it can do.
2. In extreme cases of differences of traction, the wheel with the least traction may spin after the axle has transferred as much torque as possible to the non-slipping wheel.

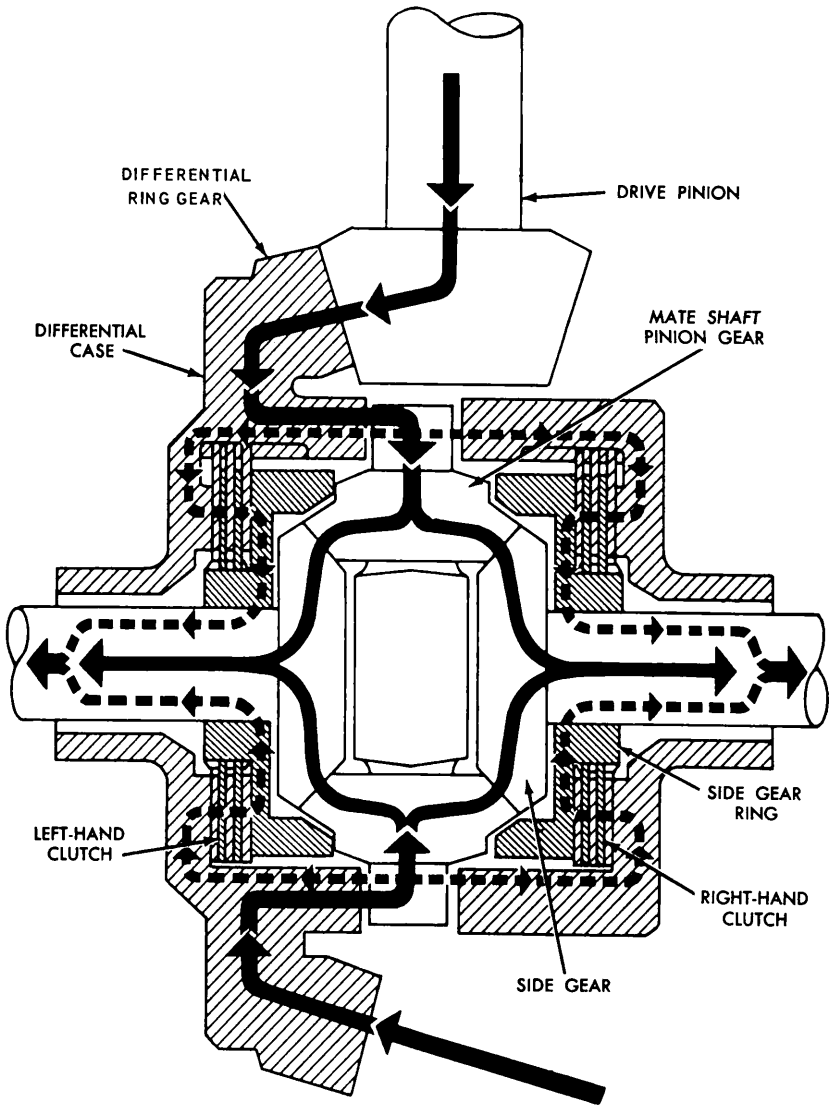

FIG. 2 Limited-Slip Differential Power Flow With Both Wheels Driving

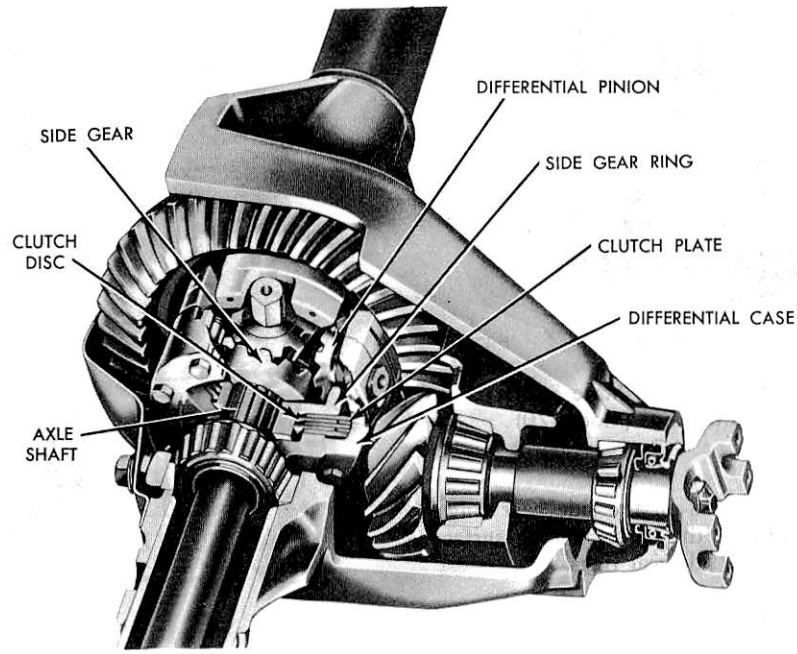

FIG. 3 Limited Slip Differential—Model 70

ADJUSTMENTS

DANA LIMITED-SLIP AXLES

For Adjustment and Repair procedures concerning Dana limited-slip rear axles and for complete specifications refer to Part 15-05.

REMOVAL AND INSTALLATION

DANA LIMITED-SLIP DIFFERENTIAL

For Dana Models 60-3D, 70 or Model 60 limited slip differential rear axle Removal and Installation procedures, refer to Part 15-05.

DISASSEMBLY AND ASSEMBLY

DANA LIMITED-SLIP AXLES

Service procedures for the Dana Model 70 axles with limited-slip differentials are covered in this section. Model 60 procedures are identical to those covered in Part 15-30 for the Model 44 axles, which differ only in size. When following the instructions however there is one exception when removing side gears, washers and limited slip clutch packs.

When doing this operation different tooling is required. Use Kit T71T-4205-A (Part of the 1971 Essential Kit), TKIT-1971-F or FX and also available separately.

The Dana limited-slip differential assembly is removed and installed in exactly the same manner as the conventional differential assembly. For these service procedures refer to Part 15-05. EST-M2C118-A (Friction modifier) is the only authorized additive

which may be used with these axles.

When axle lubricant has been drained for front or rear axle repair (limited slip only), refill axle with the specified quantity of ESW-M2C105-A and add 4 oz. of EST-M2C118-A friction modifier for rear axles and 2 oz. of EST-M2C118-A friction modifier for front drive axles.

DISASSEMBLY

MODEL 70

The differential bearings need not be removed to overhaul the limited-slip differential.

1. Mark the ring gear half and cover half of the differential case so that they can be reassembled in the same relative positions. Mark the pinion mate shafts and their corresponding ramps so that they too can be reassembled in the same positions (Fig. 4).
2. Clamp the differential assembly in a soft-jawed vise and loosen but do not remove the bolts that hold the case halves together.
3. Place the differential assembly on the bench with the ring half of the case down. Remove the case attaching bolts, and then remove the cover half of the case (Fig. 5) on model 70 differentials.
4. Remove the upper mate shaft, side gear, side gear ring, and clutch pack (Fig. 6). Keep these parts with the cover half of the case so that they can be installed in their original positions.
5. On model 70 differentials remove the corresponding parts from the drive gear half of the case.
6. On all models clean all parts thoroughly and dry with compressed air.
7. Inspect the clutch plates and discs for cracks, excessive wear, and distortion. Both the discs and the plates, except the two Belleville spring plates should be flat. Any dished plates or discs, other than the spring plates, must be replaced. In the event that one or more of the plates, discs, or spring plates or discs need replacing, it is suggested that the entire stack of plates, discs, and spring plates or discs on each side be replaced.

   Inspect all other parts and replace any part that appears to be worn or damaged (Fig. 7).
8. Inspect the pinion mate shaft surfaces and the ramp surfaces on the case for excessive wear or pitting.
9. Inspect the side gear and pinion gear teeth. Inspect the pinion gear races that bear on the side gear rings. Inspect the corresponding surface on the side gear rings.

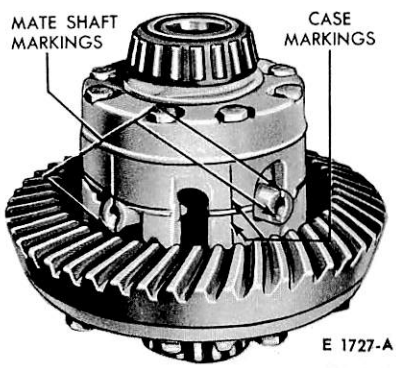

FIG. 4 Case and Mate Shaft Markings (Model 70)

ASSEMBLY

1. Place the side gear ring from the drive gear half of the case on a pinion flange (Fig. 8) or something similar, so that it is about 4 inches above the bench. Coat the clutch plates with axle lubricant.
2. Refer to Fig. 8 and assemble the parts in the order indicated for the particular axle model being repaired.
3. Place the ring gear half of the case over the clutch pack and side gear ring. Make sure that the clutch plate lugs enter the slots in the case and that the case bottoms on the clutch pack (Fig. 8).
4. Grasp the flange and the case to hold the assembly together, and then turn the case half upside down.
5. Place the proper side gear in the side gear ring.
6. Install the axle shaft spacer in the cross shaft, see Fig. 8 for proper placement of the spacers.
7. Place the mate shaft and pinions on the side gear ring (Fig. 9). Align the mate shaft and case markings.
8. Install the cover half mate shaft and pinions. Align the point markings.
9. Place the side gear on the pinions, and then place the side gear ring on the side gear and pinions.
10. Assemble the clutch pack on the side gear according to the arrangement shown in Fig. 10. Align the clutch plate lugs, and install all parts in the case.
11. Place the cover half of the case over the assembly (Fig. 5). Align the case mark made before disassembly.
12. Install all the case bolts and turn each one on a few threads. Using both axle shafts, align the splines of the side gear and the side gear ring (Fig. 6) on both sides of the case. With the axle shafts in position, torque the case bolts evenly and alternately to 35-45 ft-lbs (Fig. 11).
13. Remove the axle shafts. **If the assembly has been properly assembled, each pinion mate cross shaft should be tight on its ramp; or, in the event there is clearance between the cross shaft and the ramp, it should be not more than 0.010 inch and be equal at all four cross shaft ends.**

DESCRIPTION

A typical Eaton Tandem Axle assembly is shown in Fig. 1.

POWER DIVIDER AND CARRIER D-SERIES AXLE

The power divider used on the D-Series axles does not have an idler shaft assembly. The input and output shafts are arranged to provide a straight-through drive to the rearward axle. The two shafts are connected only through the power divider differential (Fig. 2).

The power divider input shaft drives the power divider differential spider. The pinions are in constant mesh with front and rear differential side gears. The front differential side gear is integral with a helical gear, which is in constant mesh with a gear splined to the forward axle drive pinion. The front helical side gear is normally free-running on the input shaft. The rear differential side gear is splined to the output shaft.

In normal operation, the power divider differential pinions drive the

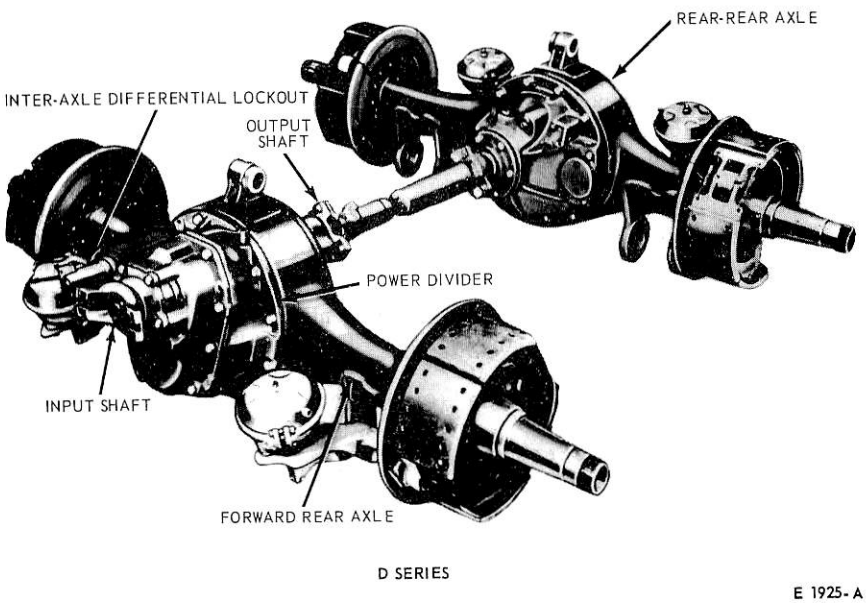

FIG. 1 Typical Eaton Tandem Axle Assembly

front and rear side gears at the same speed. The front helical side gear drives the forward axle drive pinion. The rear side gear drives the rearward axle drive pinion through the output shaft and inner-axle drive shaft.

In the D-Series axles there is no reduction in the power divider unit. In the double reduction units, a second reduction is obtained by using a planetary two-speed differential in which the sun (sliding clutch) gear is permanently locked in the low-speed position.

In the 2-speed units, the air shift unlocks the sun gear from the carrier housing and locks it to the differential case for high-speed operation.

The 8.38:1 ratio, for example, is obtained by a 6.14:1 reduction between the pinion and ring gear and a further planetary gear reduction of 1.364:1 between the ring gear and the axle shafts (except model 30D, which has a 1.390:1 reduction).

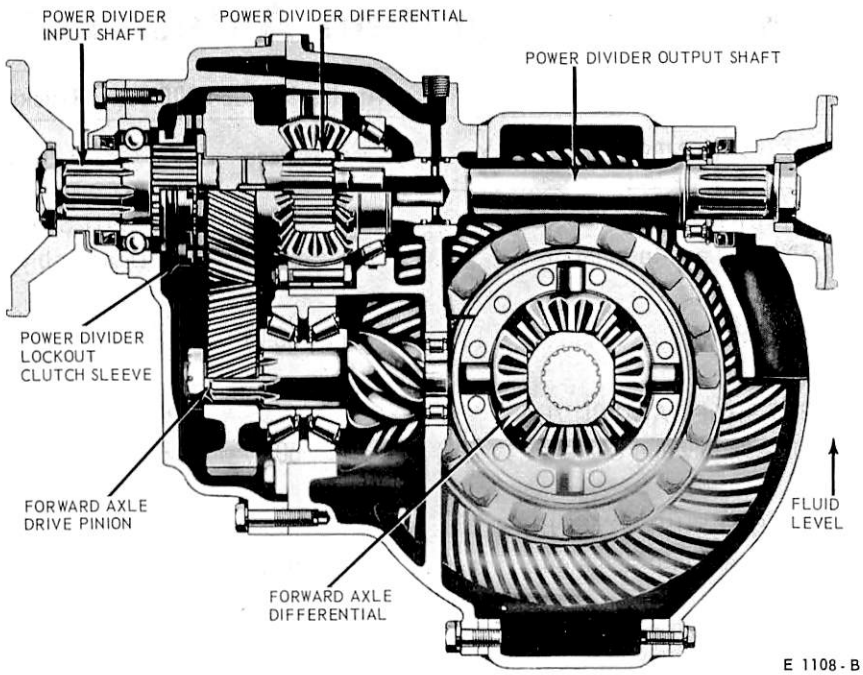

FIG. 2 Inter-Axle Differential Power Flow— D-Series Axles

POWER DIVIDER LOCKOUT CONTROL SYSTEMS

During normal vehicle operation, the power divider differential lockout is maintained in a disengaged position by a spring. In the case of straight air there is no air supplied to the lockout valve unless the axle is in the low range thus maintaining the lockout in the disengaged position. When the lockout mechanism is engaged by activating a straight air valve, the sliding clutch gear engages the forward helical gear on the input shaft, locking out power divider differential action, and providing positive drive to both axle units. Thus, equal driving power to the drive pinions in the forward and rearward axles is provided, and maximum traction is available for pulling through deep sand, mud, or snow.

The lockout mechanism must be engaged only when the truck is standing still with the wheels not rotating. It should be engaged only as long as extra traction is needed.

Continuous, unnecessary engagement of the lockout mechanism will result in excessive tire wear, and may cause damage to the axles when tires are of different diameters.

STRAIGHT AIR SYSTEM

The lockout will operate only in **LO range, when the shift unit actuating lever depresses the lockout control valve. This permits air pressure to be applied to the power divider lockout cylinder (Fig. 3). The air pressure against the piston causes the power divider differential clutch sleeve to lock out the differential.**

When the control switch is turned to the Lockout Disengaged position, the solenoid air valve closes and releases the air pressure from the cylinder. With air pressure cut off, the compressed spring disengages the sliding clutch sleeve and holds it in the unlocked position in the power divider.

2-SPEED TANDEM DRIVE AXLE

DESCRIPTION

The Eaton 2-Speed Tandem Drive Axle consists of two planetary-type, two-speed axle units, coupled with a power divider and an inter-axle differential.

The over-all operation of this axle system is the same as any other two speed tandem installation using an inter-axle differential.

2-SPEED TANDEM AXLE STRAIGHT AIR SHIFT SYSTEM

DESCRIPTION

This shift system basically includes: (1) A 2-position, manually operated air shifter valve, (2) a quick release valve, and (3) two axle shift units (Fig. 3). The entire system operates at reservoir tank air pressure. On vehicles not equipped with automatic safety brakes, an ignition-controlled solenoid valve exhausts the system, which downshifts the axles when the ignition switch is turned off. The electrical circuit is protected by a circuit breaker.

In operation, the air shifter valve (in gear shift knob) supplies air through the quick release valve to the axle shift units. Air pressure in the shift units shifts axles to high range. To shift axles to low range, air pressure is exhausted at shifter valve, which exhausts air pressure at quick release valve, following shift units to return to low.

"LO" RANGE OPERATION

Shifter knob is in "LO", shifter valve is closed and no air pressure is present in air lines to either shift unit. Axles are held in low range by shift unit return springs.

"HI" RANGE OPERATION

Shifter knob is in "HI", shifter valve is opened to allow air pressure through quick release valve to both shift units. Both axles are held in high range by shift unit air pressure.

SPEEDOMETER ADAPTER

For vehicles with transmission drive speedometer, the system incorporates a speedometer adapter. Operation is controlled by an electrical switch (normally closed...opened by air pressure) mounted in the air line near the quick release valve.

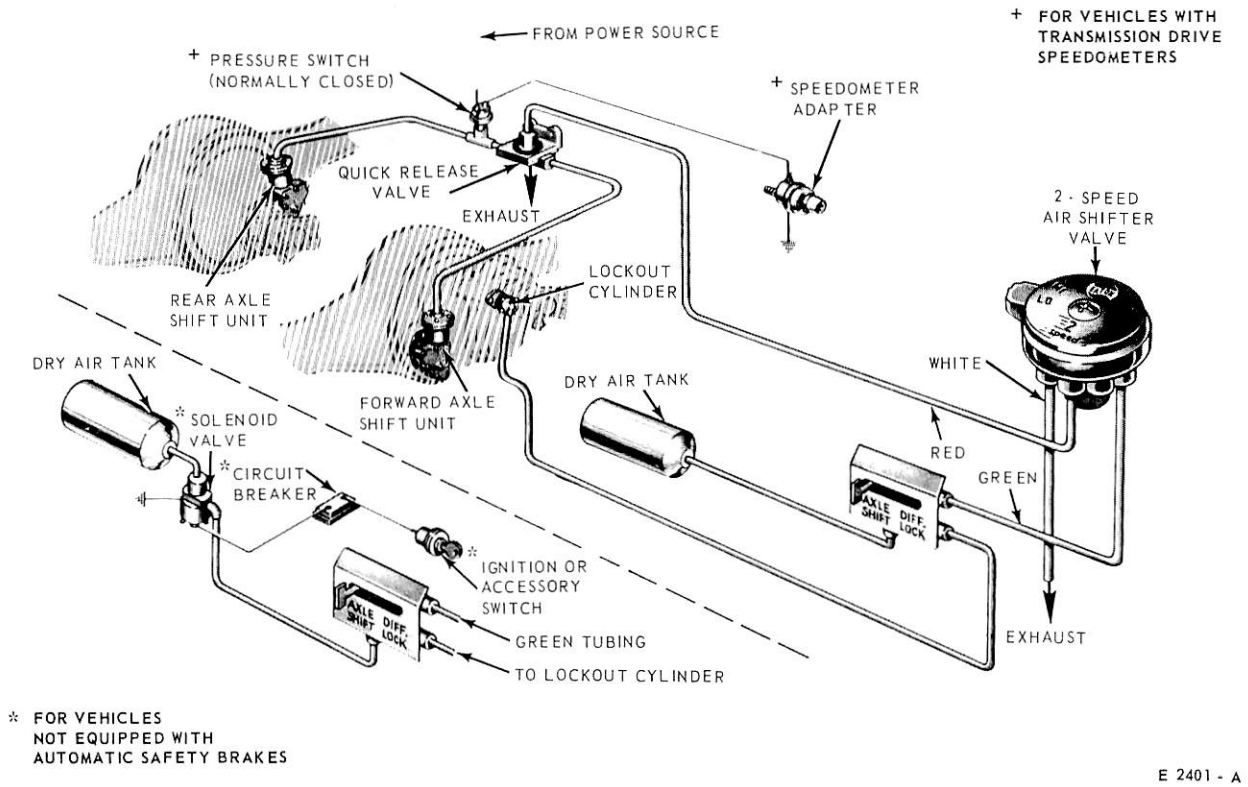

FIG. 3 Two-speed Tandem Axle Straight—Air Shift System

ADJUSTMENTS

REAR WHEELS, BEARINGS AND SEALS

Axle shafts, wheel hubs, bearings, and grease seals can be replaced, lubricated, or adjusted without removing the differential carrier assembly from the axle housing or the rear axle assembly from the vehicle. See Part 15-01, Testing for procedures.

AIR LOCKOUT SHIFT CYLINDER REPAIR

1. Remove the cover retaining nuts, lock washers and cover from the shift cylinder body. Discard the cover grommet. Remove the nut, flat washer, and grommet from the push rod.
2. Remove the cap screws, lock washers, shift cylinder body assembly and gasket from the case cover. The shift cylinder body assembly includes a piston, piston grommet or O-ring, two felt oilers and a filter (Fig. 4).
3. Remove the compression spring from the push rod. Remove the retaining screws and remove the divider cover; then remove the sliding clutch and shift fork assembly from the case cover.
4. Inspect the parts for excessive wear or damage and replace as required.
5. Place the felt seal and seal retainer in the recess in the case cover.
6. Assemble the shift fork and sliding clutch to the case cover as follows: partially insert the push rod in the case cover, engage the sliding clutch with the shift fork, and then push the entire assembly into the correct mounting position in the case cover.
7. Place the compression spring, gasket, and shift cylinder body over the push rod and on the case cover. Install the retaining screws and lock washer.
8. The piston felt oilers should be soaked in SAE 30 oil for one hour before assembly.
9. Install the felt oilers and O-ring on the piston and insert the piston assembly into the shift cylinder body and onto the push rod. Secure the piston to the rod with the flat washer and nut.
10. Install a new grommet on the cylinder cover, install the cover to

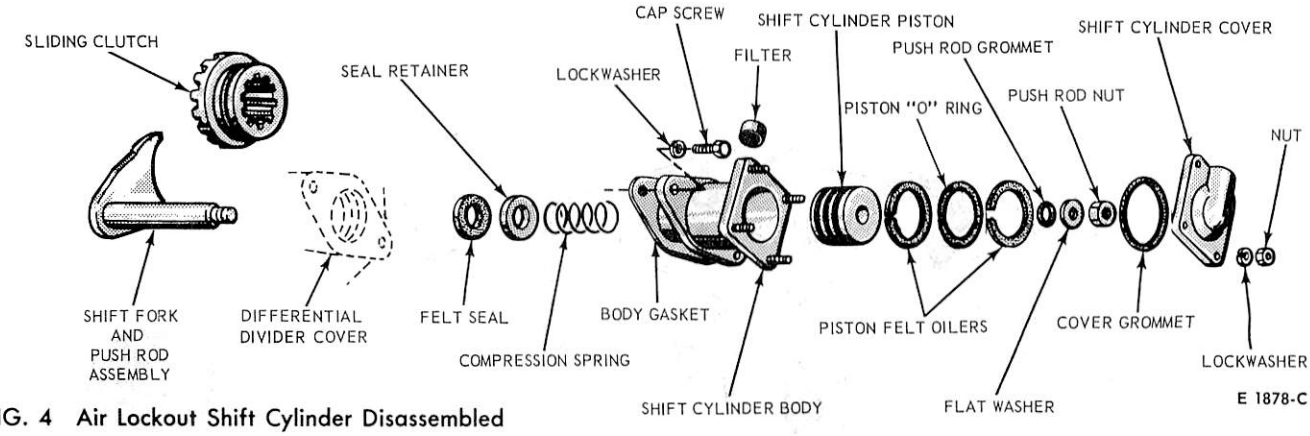

FIG. 4 Air Lockout Shift Cylinder Disassembled

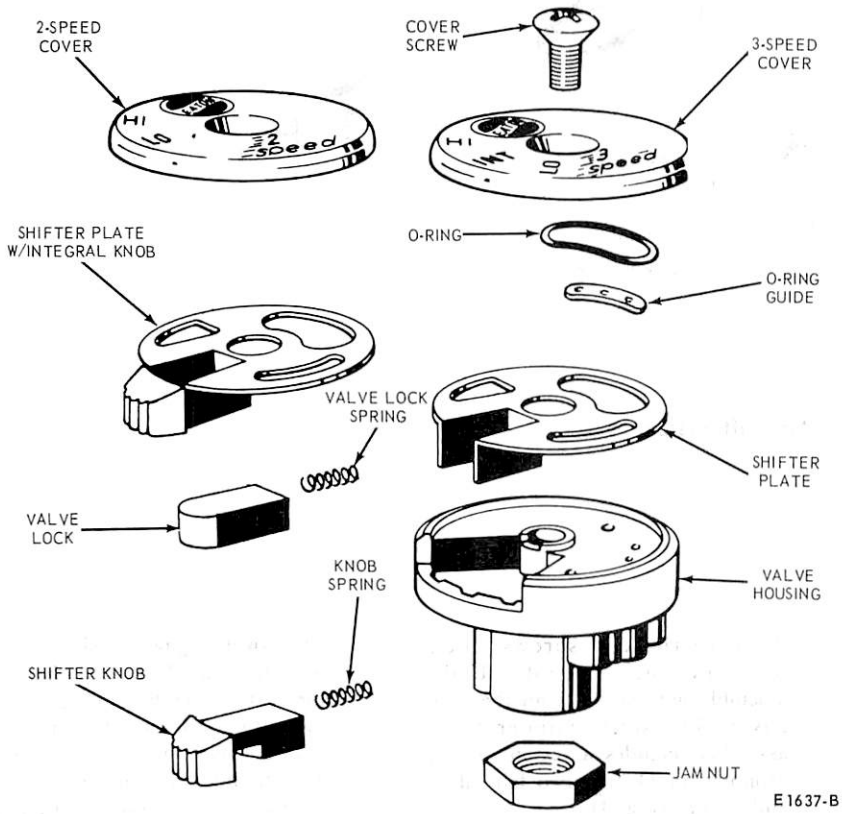

FIG. 5 Exploded View of 2-Speed Straight Air Shift Valve

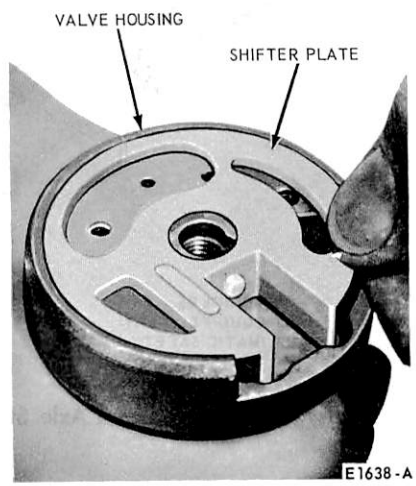

FIG. 6 Installing Shifter Plate—2-Speed Straight Air

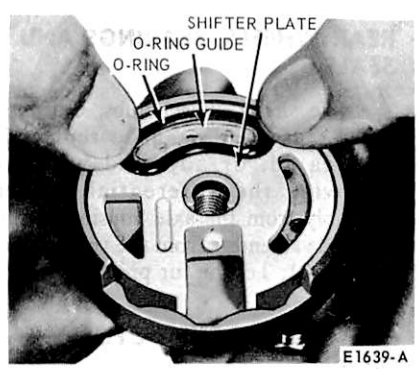

FIG. 7 Installing Guide and O-Ring—2-Speed Straight Air

the cylinder body, and secure with the retaining nuts and lock washers. Install the divider cover.

2-SPEED TANDEM CONTROL SYSTEM REPAIR

SPEEDOMETER ADAPTER

The speedometer adapters are lubricated and sealed for the life of the unit. No maintenance is required. Replace any damaged unit. It is not necessary to replace both units if only one has failed.

LOCKOUT SWITCH (AT SHIFT UNIT)

Replace the lockout switch as an assembly.

AIR SHIFTER VALVE REPAIR

Removal

1. Disconnect air lines from the bottom of the control switch.
2. Unscrew the switch from the gear shift lever.

Air supply to valve must be shut off before the valve is serviced. The shifter valve can be disassembled for service without removing the assembly from the gear shift lever.

Disassembly

1. Remove screw from cover, then lift off cover and remove shifter knob, knob spring, shifter plate, O-ring guide and O-ring from valve housing (Fig. 5).
2. If housing requires replacement, disconnect air lines, loosen jam nut, then unscrew housing from shift lever.

The shifter valve should be disassembled, inspected, cleaned and lubricated every 50,000 miles. Lubricate all moving parts with **barium-base grease. No other type lubricant should be used.**

Assembly

If housing was removed, install jam nut on shift lever. Thread housing on shift lever and tighten jam nut. Connect air lines (Fig. 3).

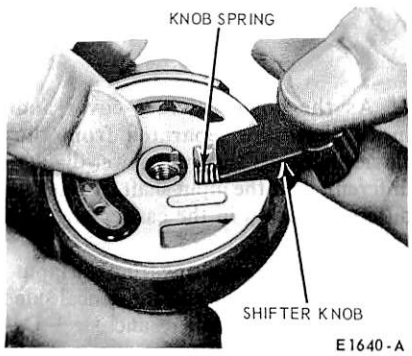

FIG. 8 Installing Spring and Shifter Knob—2-Speed Straight Air

1. Place shifter plate in mounting position on valve housing (Fig. 6).
2. Preassemble guide and O-ring, then place this assembly in mounting position in shifter plate (Fig. 7).
3. Hold shifter plate in position with one hand, then install spring and shifter knob. Install cover and fasten with screw (Fig. 8).

REMOVAL AND INSTALLATION

REAR AXLE HOUSING

If the forward or rear axle housing is to be removed from the vehicle, refer to Tandem Axle Suspension, Parts 14-40 and 14-41.

POWER DIVIDER AND CARRIER D-SERIES AXLE REMOVAL

1. Block the wheels to prevent the vehicle from moving.
2. Drain the power divider and axle housing.
3. Remove the vacuum or air shift components as equipped; then remove the lockout cylinder and mounting bracket from the power divider.
4. Disconnect the drive shaft at the input shaft.
5. Remove the air brake line from the right-hand forward axle brake chamber and the connector on the axle housing.
6. Remove both axle shafts.
7. Remove the carrier to housing stud nuts.
8. Position a roller jack, with a cradle, beneath the power divider and carrier. Fasten the assembly to the cradle (Fig. 9).
9. Disconnect the inter-axle drive shaft at the power divider output shaft flange.
10. Hold the output shaft flange, and remove the flange nut. Pull the flange.
11. Carefully remove the power divider and carrier from the housing. As the power divider and carrier are moved out of the housing, the output shaft and roller bearing inner race must slide out of straight rollers in the axle housing cover (Fig. 13).
12. Remove the power divider and carrier from under the vehicle.

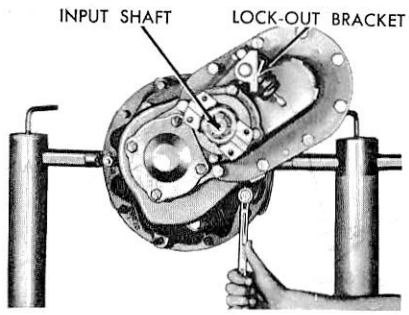

FIG. 9 Removing Power Divider Front Carrier— Typical

Installation

1. **Clean the inside of the axle housing.**
2. Remove the power divider output shaft flange seal from the axle housing rear cover. Remove the flange spacer and the roller bearing from the cover.
3. Mount the power divider and carrier on a roller jack.
4. Place a new gasket on the axle housing. Install the gasket dry to prevent leakage due to creeping caused by sealing compound.
5. Start the carrier housing on the axle housing studs and pull it into position with the stud nuts. Torque the nuts to specification.
6. Install the roller bearing outer race and cage in the housing rear cover. Place the spacer next to the bearing (Fig. 13).
7. Install a new seal in the housing cover for the output shaft flange.
8. Start the flange on the output shaft. **Hold the flange** and pull the flange into position with the flange nut and flat washer. Torque the nut to specification, and install a new cotter pin.
9. Connect the inter-axle drive shaft. Connect the drive shaft at the input shaft flange.
10. Install and connect the power divider lockout unit. Install the air line to the brake chamber.
11. Place new gaskets on the wheel hub studs and install the axle shafts. Torque the stud nuts to specification.
12. Fill the power divider and axle housing with the proper amount and grade of lubricant.

REARWARD AXLE CARRIER—ALL MODELS

For Removal and Installation of the rearward axle carrier, follow the procedures in Adjustments in Part 15-15 (Single-Speed) or Part 15-20 (Two-Speed).

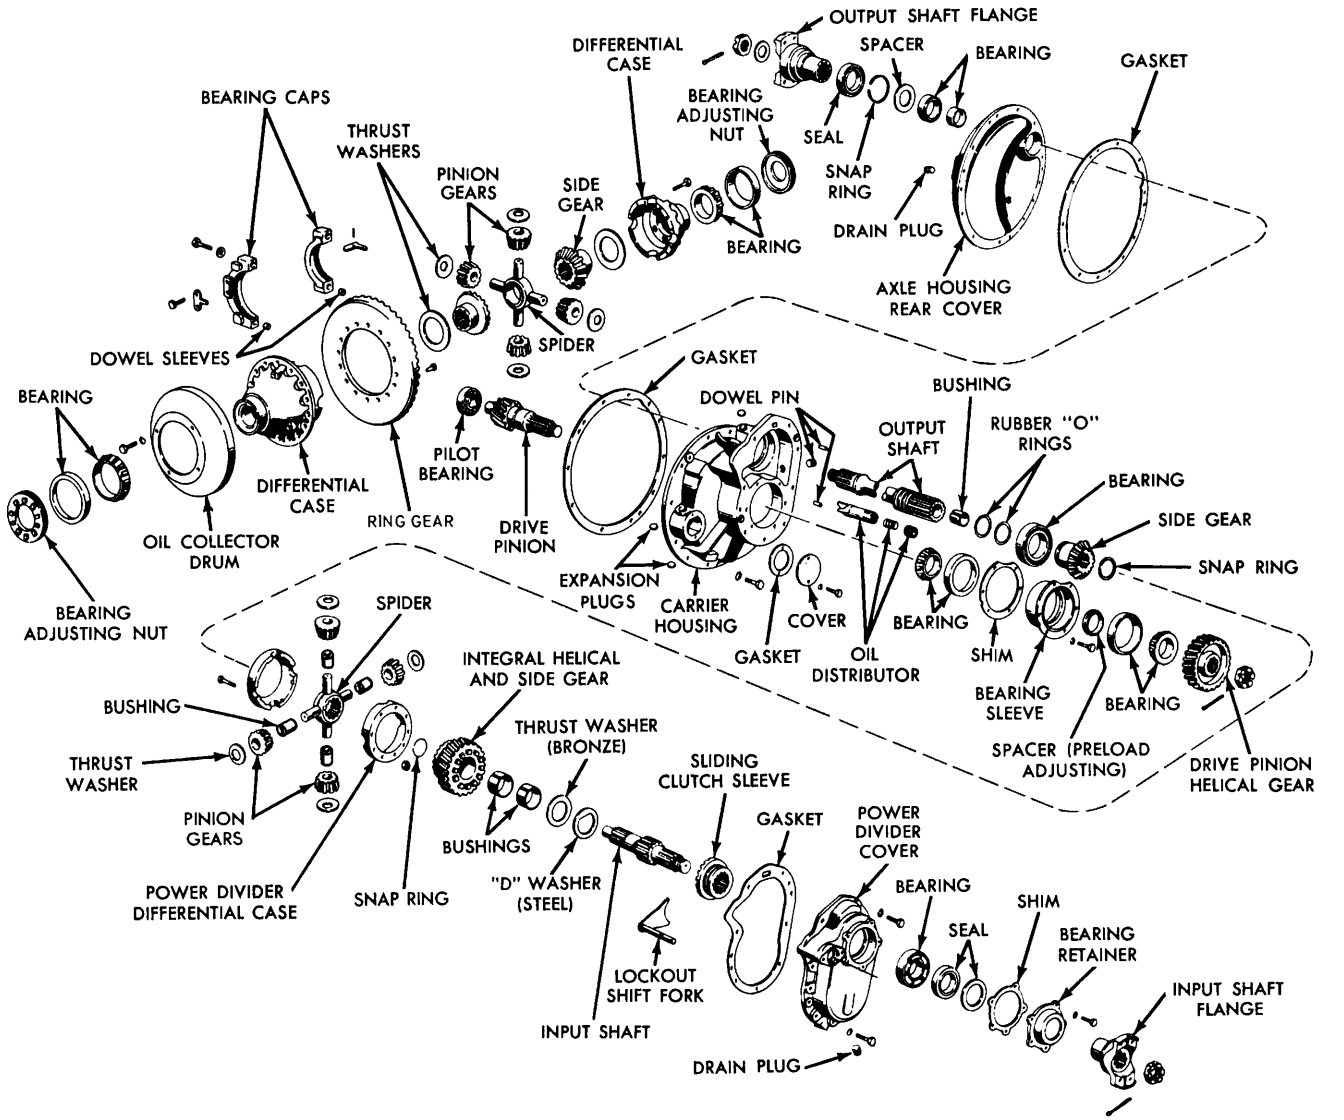
DISASSEMBLY AND ASSEMBLY

DISASSEMBLY OF POWER DIVIDER AND CARRIER— 30D, 34D and 38D SINGLE REDUCTION AXLES

1. Disconnect the drive shaft at the power divider input flange and tie the drive shaft to the frame so it is out of the way.
2. Disconnect the power divider lockout shift control air line or linkage, whichever is applicable.
3. If the input flange nut is accessible on the vehicle with a socket and breaker bar, remove the cotter pin from the nut and remove the hardened washer and flange nut. If the input flange nut is not accessible on the vehicle, remove the power divider cover with the input flange and nut in place. Mount the power divider cover in a floor stand and then remove the input flange, cotter pin and nut. Flange can be held in a vise if desired.
4. Tilt the overhaul stand so that the power divider and carrier are in normal operating position.
5. Remove the power divider cover by removing the 9 cover to carrier bolts. Carefully work the power divider cover off its dowel pins, using a transmission jack to help support the weight of the cover and also to receive the power divider cover when it is removed (Fig. 10).

As the power divider cover and input shaft are separated from the carrier housing, slide the power divider differential off the input shaft so that the differential stays in the carrier housing (Fig. 11).

6. Remove the snap ring from the input shaft and then lift off the helical side gear, thrust washer, and steel D-washer (Fig. 12).
7. Remove the bearing retainer and shim pack (Fig. 12).
8. Manually drive the input shaft and bearing from the rear of the power divider cover.
9. Mark the power divider differential case for proper assembly, then remove the bolts that hold the



E1142-C

FIG. 10 Power Divider and Carrier—30D and 34D

differential case halves together.
10. Remove the snap ring at the front of the output shaft (Fig. 13) and pull the output shaft toward the rear and out of the side gear. Remove the O-rings from the output shaft.
11. Lift off the side gear and bearing assembly from the carrier housing.
12. Lock the differential drive gear to the carrier housing, and then remove the drive pinion shaft end nut.
13. Remove the helical gear from the drive pinion shaft.
14. Remove the oil distributor (Fig. 14), if so equipped.

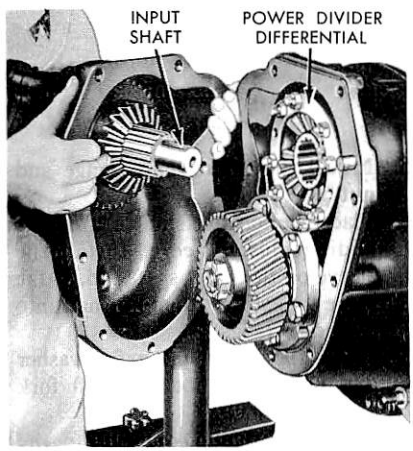


FIG. 11 Removing or Installing Power Divider Input Shaft and Cover

15. Mark the differential bearing adjuster nuts for location, loosen the bearing cap bolts then loosen one adjuster nut to relieve bearing preload.
16. Remove the differential bearing caps, then remove the differential assembly. For service procedures on single-reduction differential assemblies, refer to Part 15-15. For the double reduction type differential, see Part 15-20.
17. Remove the pinion bearing sleeve to carrier bolts. From the pinion pilot end, drive the pinion bearing and sleeve as an assembly out of the front of the carrier housing (Fig. 15). For service procedures on the ring gear and pinion assembly refer to Part 15-01.

ASSEMBLY OF POWER DIVIDER AND CARRIER 30D AND 34D

DRIVE PINION AND DIFFERENTIAL

1. Select the proper shim for the pinion bearing sleeve. Refer to Part 15-01, Testing for SHIM SELECTION.
2. Install the drive pinion and sleeve in the carrier housing (Fig. 16).
3. Install the helical gear on the drive pinion shaft. There is a chamfer on one end of the helical gear hub spline. The chamfered end goes toward the rear of the carrier. Start the nut and hardened washer on the drive pinion shaft.
4. Rotate the carrier housing and install the differential assembly, bearings and caps.
5. Lock the ring gear to the carrier housing, and torque the drive pinion nut to specification. Install the cotter pin.
6. Adjust differential bearing preload and pinion and ring gear backlash as given in Part 15-01.
7. Check pinion and ring gear tooth contact as given in Part 15-01.
8. Install the oil distributor (Fig. 15), if so equipped.

POWER DIVIDER OUTPUT SHAFT

1. Press the tapered bearing on the output shaft side gear.
2. Install two new O-rings on the output shaft.
3. Install the rear snap ring on the shaft; then install the side gear and bearing on the output shaft. Install the snap ring at the front end of the output shaft.
4. Lubricate the bearing, O-rings, and output shaft bushing. Install the assembly in the carrier housing (Fig. 17).

POWER DIVIDER INPUT SHAFT AND COVER

1. Press the bearing on the threaded end of the input shaft (Fig. 12). Coat the outer race of the new bearing with Locktite Sealer, C3AZ-19554-A. This will prevent the outer race from creeping in the bore of the power divider cover.
2. Press the shaft and bearing into the

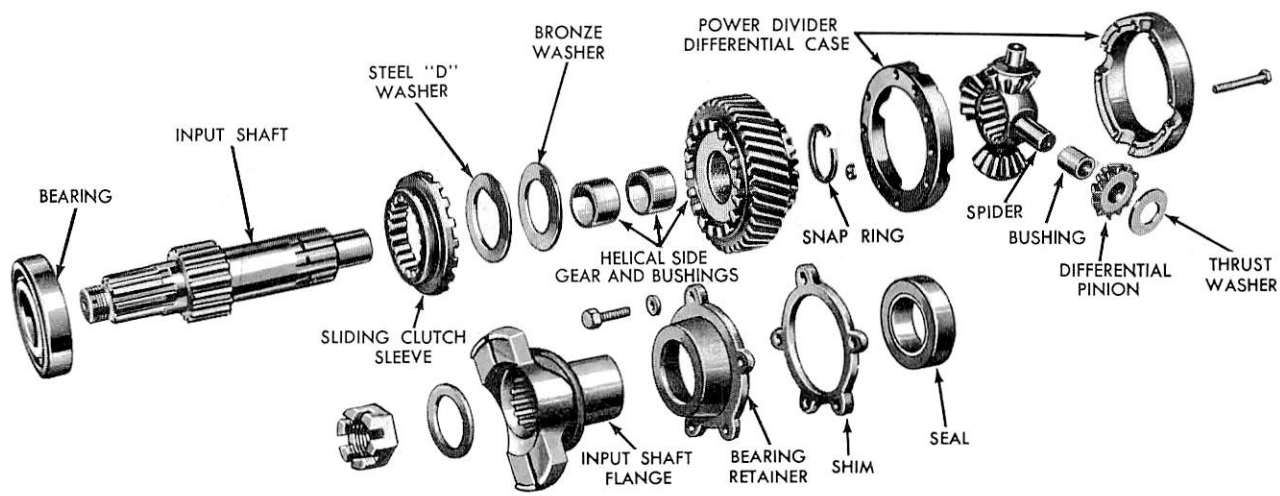

FIG. 12 Inter-Axle Differential Input Shaft and Related Parts

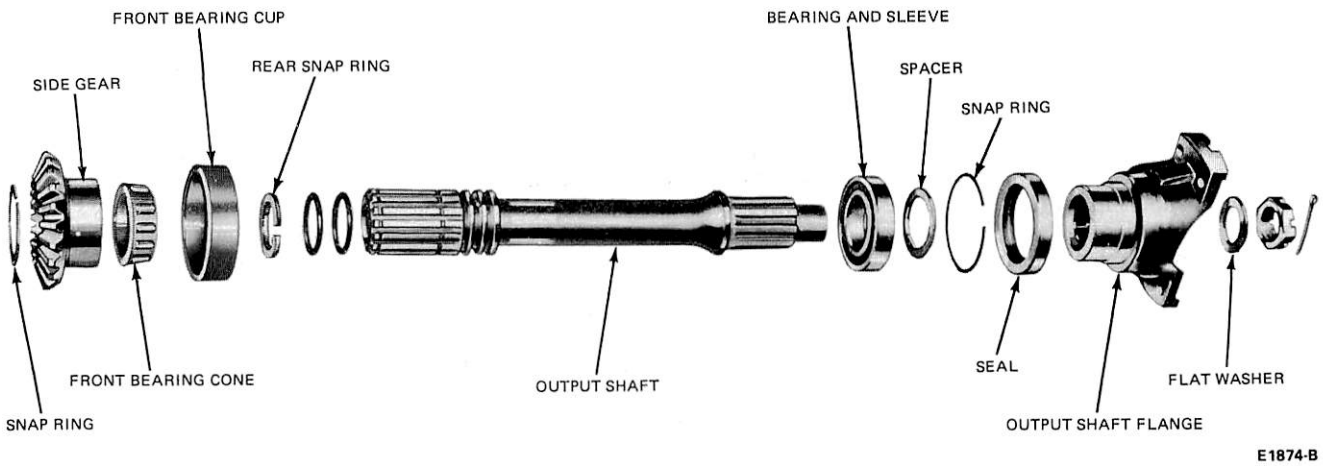

FIG. 13 Output Shaft and Related Parts

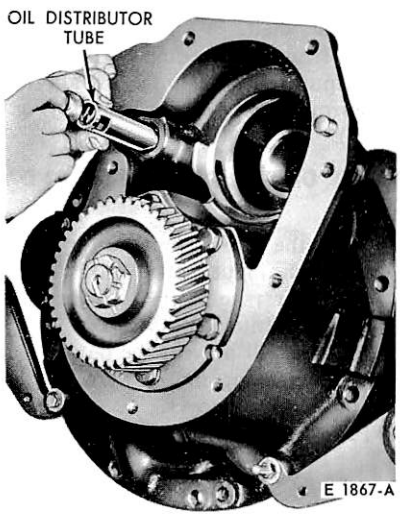

FIG. 14 Installing Oil Distributor

power divider cover, engaging the sliding clutch. The oil drain back holes in the carrier cover, the shims, and the bearing cover **must be in alignment.**

3. Install a new seal and felt in the input shaft bearing retainer (Fig. 10). Install the input shaft bearing retainer without a shim. Tighten the retainer bolts only enough to bottom the retainer on the bearing outer race. With a feeler gauge, check the clearance between the bearing retainer and power divider cover.
4. Remove the retainer and install a shim equal to the clearance determined by the feeler gauge, plus 0.001. This shim will provide a seal at the outer edge of the retainer. Torque the retainer to cover bolts to specifications.
5. Install the input shaft flange and nut.
6. Place the lockout shift fork on the sliding clutch sleeve. Install the sleeve on the input shaft and, at the same time, insert the fork shaft into the cover (Fig. 10).
7. Install the return spring, flat washer and pin on the lockout shift fork shaft.
8. Place the steel D-washer on the input shaft. Align the flat on the washer with the flat on the shaft. Retain the washer with grease.
9. Place the bronze washer against the steel washer. **Retain it with grease.**
10. Install the integral helical and side gear on the input shaft and against the bronze washer. Install the snap ring at the front of the integral helical and side gear. This snap ring

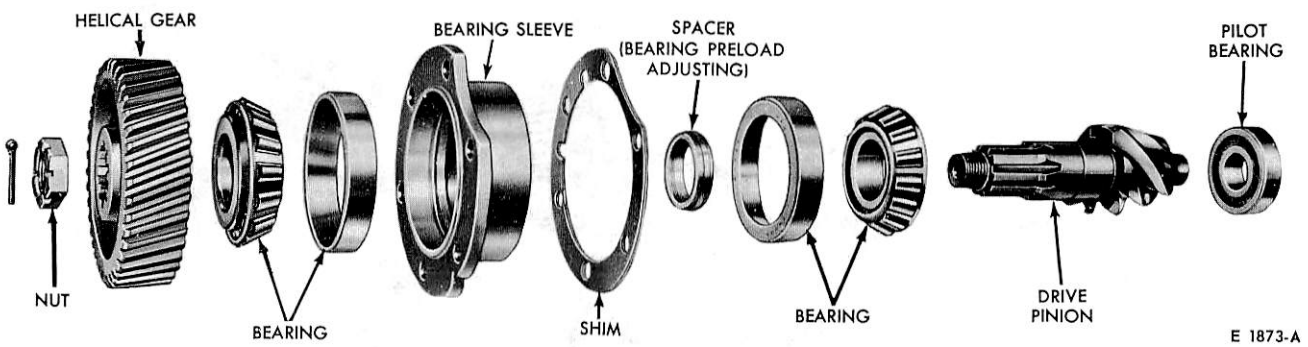

FIG. 15 Drive Pinion and Related Parts

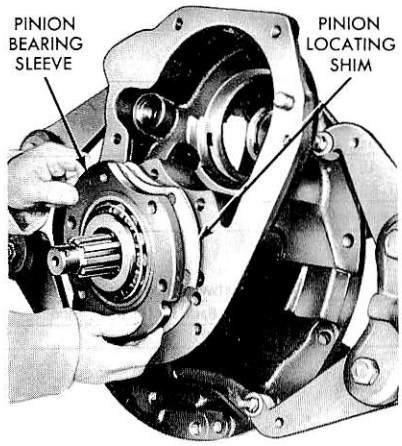
will prevent the D-washer from sliding out of position.

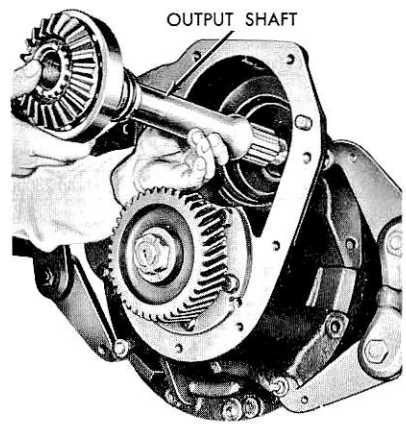
11. Place the assembled power divider differential in the carrier housing with the bolt heads in (nuts out) as shown in Fig. 11. **If the differential assembly is installed with the bolt heads reverse to the foregoing, the nuts will contact the power divider case with resultant serious damage to the rear axle assembly.**
12. Place a new gasket on the carrier housing. Assemble the power divider input shaft and cover assembly to the carrier housing (Fig. 11). Start the power divider cover to carrier housing bolts and tighten them carefully to pull the cover against the carrier housing on the dowel pins. If the cover does not move into position easily, the steel D-washer on the input shaft may have slid out of position. As soon as the cover is in normal position, hold the input shaft flange and turn the output shaft. If the input shaft can be held while the output shaft is turning, the steel washer is properly positioned.



E 1866-A

FIG. 16 Installing Drive Pinion and Sleeve

13. Torque the power divider cover to carrier housing bolts to specification.
14. Hold the input shaft flange and torque the flange nut to specification.



E 1868-A

FIG. 17 Installing Output Shaft

15. Install the lockout shift lever and bracket on the power divider cover. Torque the bracket bolts to specification.

DESCRIPTION

An inter-axle differential is mounted on the forward axle (Fig. 1). The inter-axle differential input and through shafts are arranged to provide a straight-through drive to the rearward axle. The two shafts are connected only through the power differential divider.

The inter-axle differential input shaft drives the inter-axle differential spider and pinions. The pinions are in constant mesh with the differential front and rear side gears. The differential rear side gear is splined to a spur-type transfer gear (through-shaft drive gear) which is in constant mesh with an idler gear. The idler gear is in constant mesh with another spur-type gear which is splined to the forward axle drive pinion. The differential front side gear is splined to the through-shaft.

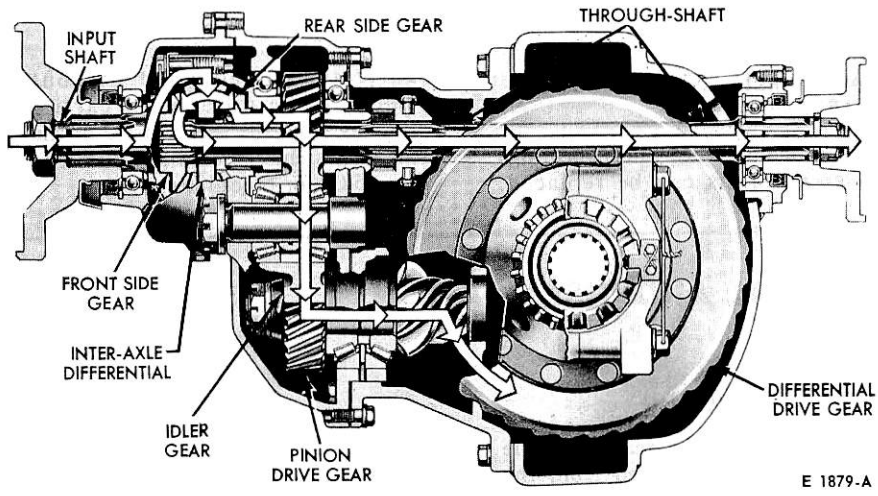

FIG. 1 Inter-Axle Differential Power Flow

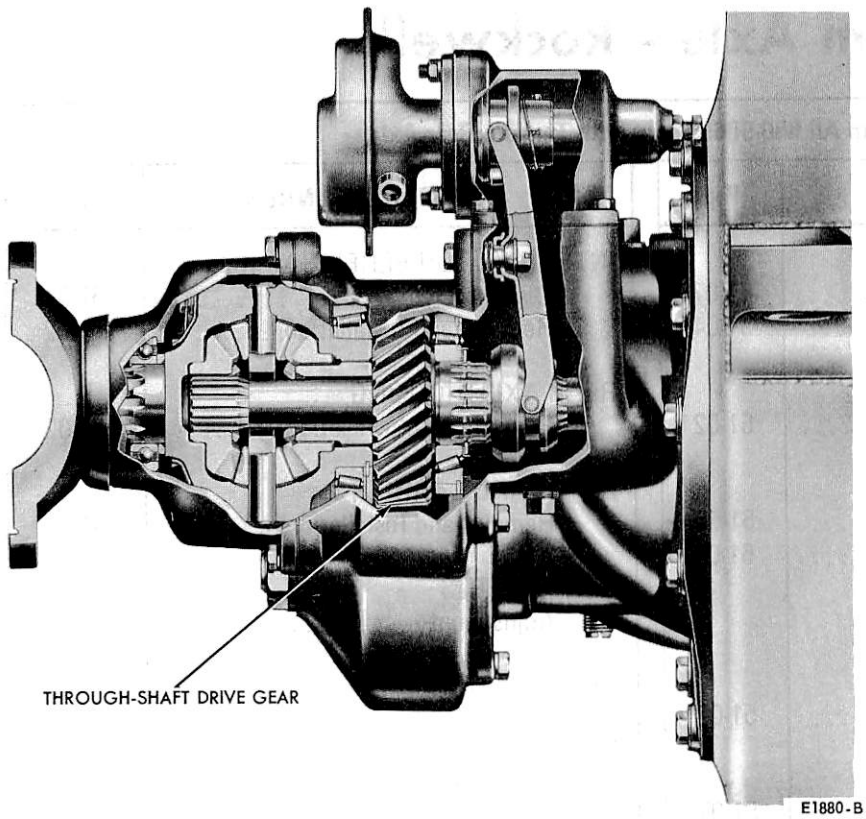

FIG. 2 Power Shift Unit

In normal operation, differential action is maintained between the forward and rearward axles. The inter-axle differential pinions drive the front and rear side gears at the same speed. The rear side gear drives the forward axle drive pinion through the transfer and idler gears. The front side gear drives the rearward axle drive shaft.

In lockout operation, both inter-axle differential side gears, the transfer gear, and the through-shaft are all locked together so that there is no differential action between the forward and rearward axles. A power shift unit mounted on the forward axle moves a splined sliding clutch sleeve which locks the transfer gear to the through-shaft (Fig. 2). Since the transfer gear is permanently splined to the rear side and is in constant mesh with the idler gear which turns the forward axle pinion gear, the forward axle is locked to the through-shaft.

The vacuum operated lockout control unit is mounted to the rear flange of the shift shaft housing assembly. For operation and repair procedures, refer to Part 15-21.

ADJUSTMENTS

REAR WHEELS, BEARINGS AND SEALS

Axle shafts, wheel hubs, bearings and grease seals can be replaced, lubricated, or adjusted without removing the differential carrier assembly from the axle housing or the rear axle assembly from the vehicle. See Part 15-01 for procedures.

REMOVAL AND INSTALLATION

REAR AXLE HOUSING

If the forward or rearward axle housing is to be removed from the vehicle, refer to Tandem Axle Suspension, Parts 14-40 and 14-41.

INTER-AXLE DIFFERENTIAL AND FORWARD CARRIER

Removal

1. Disconnect the forward drive shaft at the inter-axle differential input shaft flange.
2. Disconnect the rear drive shaft at the through-shaft flange.
3. Remove the plug from the bottom of the axle housing and drain the lubricant. Drain the lubricant from the inter-axle differential cover by removing the bottom plug.
4. Remove the axle shaft, stud nuts and lock washers.

If tapered dowels are installed in the axle shaft flange, hold a short drift firmly in the center of the axle shaft flange, and then strike it sharply to loosen the dowels. Remove the dowels and then remove the axle shaft.

Tapered dowels are not used at the axle shaft flange on most of the larger trucks. On these flanges, two puller threads are provided. Use one or both puller threads to remove the axle shafts (Refer to Part 15-01).

5. Remove the attaching screws and lock washers, and remove the shift shaft housing assembly (Fig. 2).
6. Remove the shift lever attaching nut, and lift out the button, shift

lever, cup and spring.
7. Remove the through-shaft, cage and flange assembly. To free the through-shaft cage from the housing bore, it may be necessary to tap the yoke with a soft mallet. While the through-shaft assembly is being drawn out from the rear of the housing, work the sliding clutch from the splines by a hand at the shift lever opening. When the through-shaft clears the opening, lift out the clutch.
8. Remove all the carrier-to-housing stud nuts except the two top nuts which should be loosened but left on the studs to prevent the carrier from falling. Break the carrier loose from the housing with a rawhide mallet.
9. Place a roller jack under the carrier, remove the two top nuts, and work the carrier free. A small pinch bar may be used to straighten the carrier in the housing bore, but the end of the bar should be rounded to prevent indenting the carrier flange.

Installation

1. Clean the inside of the axle housing and install a new gasket over the housing studs.
2. Mount the inter-axle differential and carrier assembly on a roller jack and roll the assembly into position. Start the carrier into the housing with four flat washers and nuts equally spacer, then tighten the nuts alternately to draw the carrier squarely into the axle housing.
3. Remove the nuts and flat washers, install the lock washers and stud nuts, and torque to specification.
4. Enter the through-shaft and cage assembly with new gasket into the cage bore in the rear of the axle housing until the forward end of the shaft is even with the shift lever opening.
5. Slide the splined clutch collar over the forward end of the shaft through the shift housing opening and ease the shaft through and into the forward side gear of the inter-axle differential, while at the same time passing the splined clutch collar through and onto the through-shaft clutch splines.
6. Install the through-shaft cage retaining screws and lock washers and torque to specification.
7. Install the shift lever spring, cup, and lever over the shift lever bolt. Properly locate the lever inner yoke in the clutch groove at this time.
8. Install the shift lever button and nut. Tighten the nut securely with a box wrench and install a cotter pin.
9. Position the shift shaft housing assembly with new gasket to the carrier, making sure that the shift lever outer yoke is properly located in the shift shaft collar groove.
10. Install the shift housing cap screws and torque to specification.
11. Install the axle shafts, and the retaining nuts and lock washers.
12. Remove the fill plugs on the axle housing and on the inter-axle differential cover to fill with proper lubricant. Install the plugs.
13. Connect the rear drive shaft at the through-shaft flange.
14. Connect the forward drive shaft at the inter-axle differential input shaft flange.

REARWARD CARRIER

Removal

1. Drain and discard the axle lubricant.
2. Remove the axle shaft, stud nuts and lock washers.

If tapered dowels are installed in the axle shaft flange, hold a short drift firmly in the center of the axle shaft flange, and then strike it sharply to loosen the dowels. Remove the dowels and then remove the axle shaft.

Tapered dowels are not used at the axle shaft flange on most of the larger trucks. On these flanges, two puller threads are provided. Use one or both puller threads to remove the axle shafts (Refer to Part 15-01).

4. Remove all the carrier-to-housing stud nuts except the two top nuts which should be loosened but left on the studs to prevent the carrier from falling. Break the carrier loose from the housing with a rawhide mallet.
5. Place a roller jack under the carrier, remove the two top nuts and work the carrier free.

Installation

1. Clean the inside of the axle housing and install a new gasket over the housing studs.
2. Mount the carrier on a roller jack and roll the assembly into position. Start the carrier into the housing with four flat washers and nuts equally spaced, and then tighten the nuts alternately to draw the carrier squarely into the axle housing.
3. Remove the nuts and flat washers, install the lock washers and stud nuts, and torque to specification.
4. Install new gaskets on the wheel hubs, and then install the axle shafts. Install the dowels, lock washers, and nuts. Torque the nuts to specification.
5. Connect the drive shaft at the rear universal joint flange.
6. Fill the axle housing with the proper grade and amount of lubricant.

DISASSEMBLY AND ASSEMBLY

DISASSEMBLY OF MAJOR COMPONENTS

1. Remove the inter-axle differential and forward axle assembly from the housing as outlined in the foregoing and mount the assembly on a repair stand (Fig. 3).
2. Remove the screws and lock washers that attach the inter-axle differential adapter case assembly to the carrier case assembly, and separate the adapter case from the carrier case (Fig. 3).
3. Remove the inter-axle differential cover-to-adapter case retaining screws and lock washers, and then separate the cover from the case.

THROUGH-SHAFT

Disassembly

The through-shaft assembly has to be removed before the forward axle carrier assembly is removed from the axle housing. See Inter-Axle Differential and Forward Carrier Removal.

1. Remove the cotter pin and nut, and remove the universal joint flange from the shaft with a suitable puller.
2. Press the through-shaft from the cage assembly by using a suitable sleeve against the bearing inner race (Fig. 4).
3. Remove the bearing retaining snap ring from the cage, and tap the

radial bearing out of the cage bore.
4. If the oil seal is damaged or worn, press it out of the cage with a suitable sleeve.

INTER-AXLE DIFFERENTIAL

Disassembly

1. While holding the input shaft flange with a suitable holder, remove the cotter pin, flange attaching nut and washer.
2. Remove the flange with a suitable puller.
3. Press the inter-axle differential case assembly from the inter-axle differential cover (Fig. 5).
4. If the original identification marks are not clear, mark the differential case halves with a punch for correct alignment on assembly.
5. Remove the lock wire and the differential case cap screws.
6. Separate the case halves and remove the spider, pinions, side gears and thrust washers.
7. Remove the oil seal and the front bearing retaining snap ring from the front side of the inter-axle differential cover.
8. Press the inter-axle differential front radial bearing out of the differential cover (Fig. 5). The bearing comes out of the front end of the cover.

ADAPTER CASE

THROUGH-SHAFT DRIVE GEAR BEARINGS

Disassembly

1. With the differential assembly (Fig. 1) removed from the axle and mounted in a stand, remove the inter-axle differential cover, inter-axle differential and adapter case, using the procedure given in this manual.
2. Cut the lockwire and remove the capscrews from the bearing cage in the adapter case, as shown in Fig. 6.
3. Lift the cage and shim pack from the adapter housing (Fig. 6). Be sure to keep the shim pack intact for reassembly.
4. Working from the rear of the adapter case, tap the through-shaft drive gear assembly from the case (Fig. 7) with a rawhide mallet.
5. If replacement is necessary, remove the bearing cups from the cage and the adapter case.
6. Remove the tapered bearings from the drive gear with a universal puller.

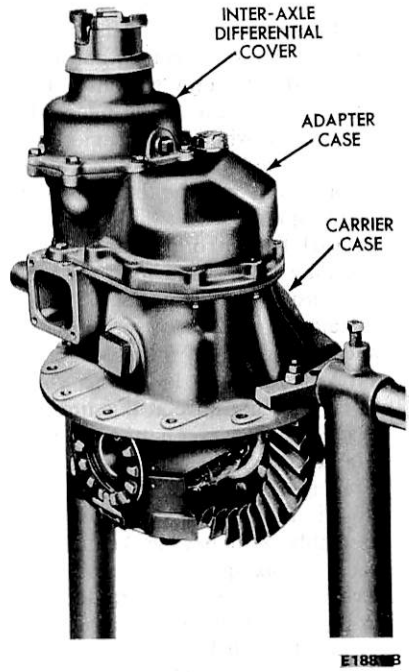

FIG. 3 Forward Axle in Repair Stand

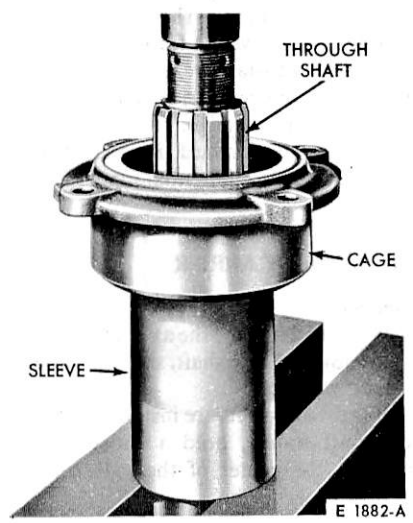

FIG. 4 Removing Through-Shaft From Cage

IDLER SHAFT AND GEAR

Disassembly

1. Remove the cotter pin, nut and spacing washer from the idler shaft. Hold the shaft at the flats on the inner end while removing the nut.
2. Slide the idler shaft and the idler gear and bearing assembly from the adapter case (Fig. 8).
3. Remove the tapered bearings from the idler gear. For complete disassembly, tap out the cups and remove the spacers (Fig. 9). Remove the snap ring from the gear bore groove.

CARRIER

Disassembly

1. Inspect the carrier before disassembly as given in Part 15-01. Check and record the backlash setting at this time.
2. With the carrier in an upright position, loosen the lock nut and back off the thrust block adjusting screw until the thrust block drops out (Fig. 5).
3. Center punch one differential bearing cup and corresponding lug for proper identification upon assembly.
4. Cut and remove the lock wire from the differential bearing cup attaching screws and from the adjuster locks.
5. Remove the attaching screws and the adjuster locks and bearing cups.
6. Lift the differential and drive gear assembly from the carrier.
7. Mark the differential case halves with a punch for proper alignment when assembling. Cut and remove the lock wire.
8. Remove the differential case nuts and bolts, and separate the case halves. Remove the spider, pinions, side gears, and thrust washers.
9. If the ring gear is to be replaced, follow the procedures outlined in Part 15-01.
10. Cut and remove the lock wire, then remove the pinion cage retaining screw (Fig. 5).
11. Remove the pinion and cage assembly from the carrier housing by tapping the end of the pinion shaft with a brass bar or hammer. Be careful not to damage the pinion radial (pilot) bearing.
12. Remove the cotter pin and the nut and washer that retain the helical drive gear to the pinion shaft.
13. Press the pinion shaft from the cage, bearings, and drive pinion gear.
14. Remove the pinion drive gear (and the gear spacer where used) from the pinion shaft.
15. Remove the pinion outer bearing from the cage, then remove the selective bearing preload spacer from the pinion shaft.
16. If necessary to replace the pinion inner bearing or pilot bearing, remove them from the pinion shaft with a puller.
17. If necessary to replace the pinion

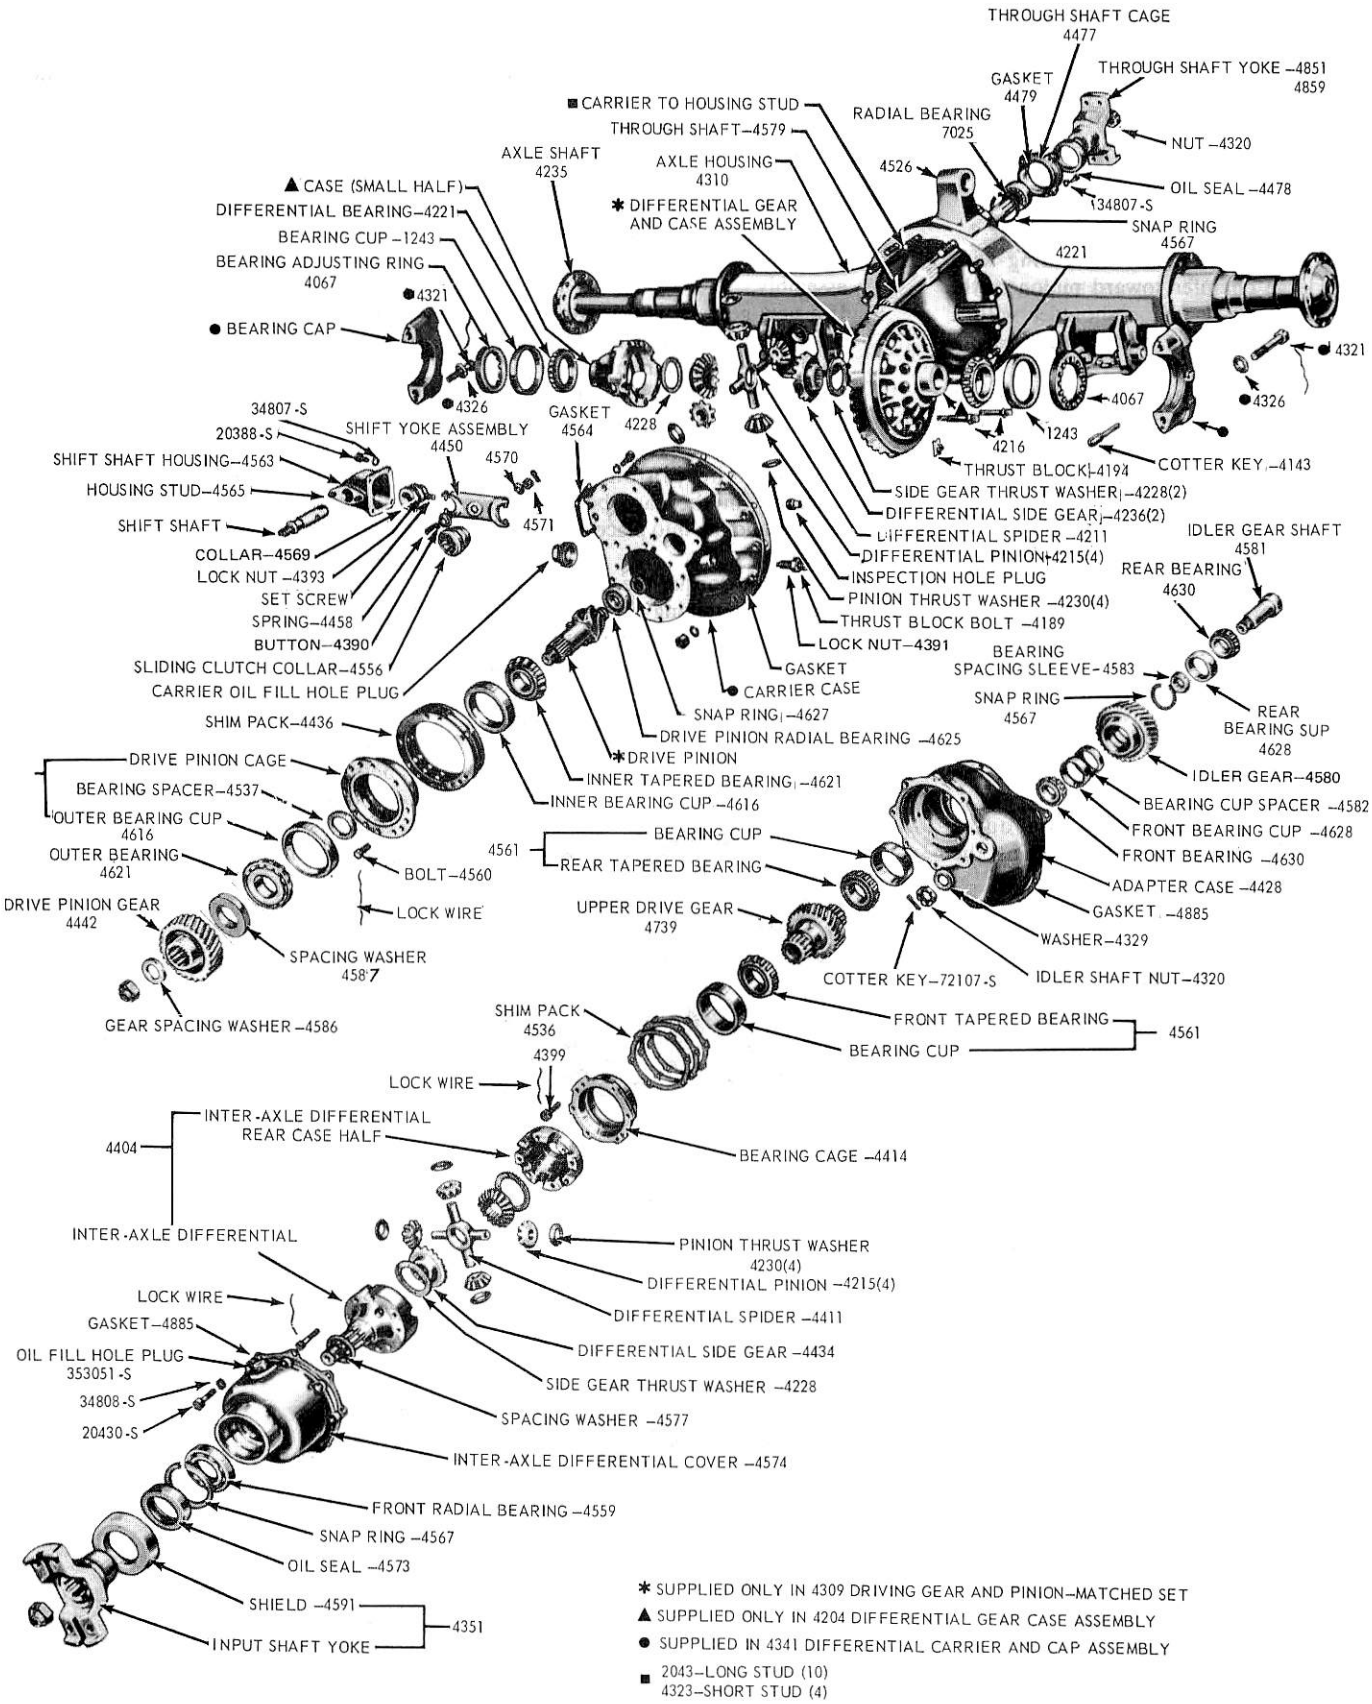

FIG. 5 Rockwell Tandem Forward Axle Disassembled

bearing cups, remove them from the cage with a suitable puller.

18. Clean, inspect and repair the component parts of the carrier as outlined in Part 15-01.

CARRIER

Assembly

1. Press the pinion rear bearing with large chamfer toward pinion teeth, against the pinion shoulder with a suitable sleeve against the bearing inner race.
2. Press the radial (pilot) bearing against the radial bearing shoulder and install the bearing retaining snap ring (Fig. 5).
3. If new cups are being installed, press the cups into the cage cup bores using a suitable sleeve and making sure that the cups are seated firmly against the cage shoulders.
4. Lubricate the bearings and cups with light machine oil, insert the pinion shaft (with pilot and inner bearings installed) into the pinion cage, and position the preload spacer over the pinion shaft against the inner bearings.
5. Firmly press the pinion outer bearing into the cage and against the preload spacer.

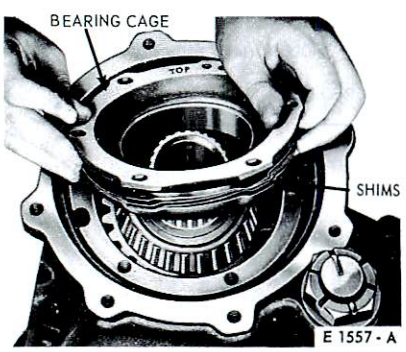

FIG. 6 Removing Shims and Cage

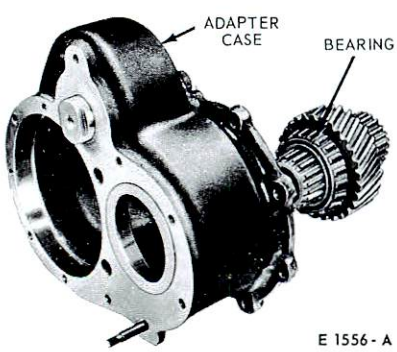

FIG. 7 Removing Gear Assembly

6. Rotate the cage several revolutions to assure normal bearing contact.
7. While in the press under pressure, check the pinion bearing preload adjustment as given in Testing, Part 15-01. Follow the method shown in Fig. 8, Part 15-01.
8. If the original pinion and ring gear set is being used, install the original shim pack on the pinion cage assembly.
9. If a new gear set is being installed, change the shim pack as outlined in Part 15-01. When necessary to replace either the pinion or the ring gear, the entire gear set should be replaced.
10. Position the pinion and cage assembly in the cage bore of the carrier, and tap into place with a soft mallet.
11. Install and torque the pinion cage-to-carrier retaining screws, but do not install the lock wire until the final carrier adjustments have been made.
12. Lubricate the differential case inner walls and all component parts with axle lubricant.
13. Position the thrust washer and side gear in the ring gear half of the differential case.
14. Assemble the spider with pinion, the other side gear and thrust washers into the ring gear half of the case.
15. Align the punch marks and install the other half of the differential case. Draw the assembly together with three equally spaced bolts and nuts.
16. Install the remaining bolts and nuts, torque the nuts to specification, and install the lock wire.
17. If the differential bearings are being replaced, press the new bearings firmly on the differential case.
18. Lubricate the differential bearings and cups with axle lubricant, and install the differential and ring gear assembly in the carrier case.
19. Adjust the differential bearing preload and backlash as outlined in Part 15-01. If the original gears are used, the backlash should be the same as that checked and recorded before disassembly. If new gears are being installed, backlash setting should be 0.010 inch.
20. Check and adjust pinion and ring gear tooth contact as outlined in Testing, Part 15-01.
21. Position the carrier with the back face of the differential ring gear upward, and remove the thrust block adjusting screw and lock nut from the carrier.
22. Place the thrust block on the back face of the ring gear and rotate the gear until the hole in the thrust block is aligned with the adjusting screw hole (Fig. 10).
23. Install the adjusting screw and lock nut, and tighten the adjusting screw

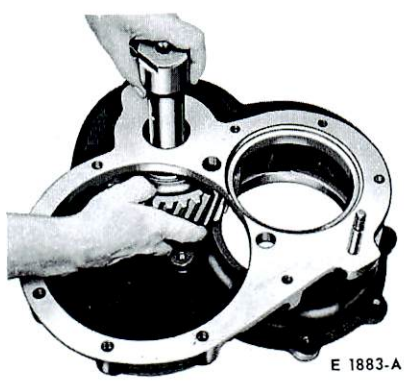

FIG. 8 Removing or Installing Idler Gear and Shaft

FIG. 9 Idler Gear and Bearing Assembly

enough to hold the thrust block firmly against the back face of the ring gear.

24. To obtain the correct adjustment of 0.010-0.020 inch clearance, loosen the adjusting screw 1/4 turn, then lock it with the lock nut.
25. Recheck to assure a minimum clearance of 0.010 during a full rotation of the differential ring gear.

ADAPTER CASE

IDLER SHAFT AND GEAR

Assembly

1. Install the snap ring into the groove of the idler gear hub (Fig. 9).
2. Press the idler gear outer bearing cup squarely against the snap ring.
3. Insert the cup spacer into the hub against the opposite side of the snap ring.
4. Press the inner bearing cup squarely against the cup spacer.
5. Position the idler gear inner and outer bearings into their cups with the bearing spacer or combination of two spacers between them.
6. Slide the complete assembly through the adapter case drive pinion opening. Position the assembly so that the bearings and spacer are aligned with the adapter shaft hole, and insert the idler shaft (Fig. 8).
7. Tap the idler shaft through the adapter case and idler gear assembly so that the idler gear outer bearing is squarely against the idler shaft shoulder. The idler shaft flat must be lined up with the corresponding flat in the carrier.
8. Hold the adapter case and idler gear assembly securely in a vise with the jaws clamped on the flatted end of the idler shaft. Install the idler shaft washer and nut, and torque the nut to 350-400 ft-lbs.
9. Mount a dial indicator to the adapter case so that the stem is set against the idler gear face, and measure the idler gear bearing end play.
10. If the bearing end play does not measure between 0.001-0.005 inch, use thinner or thicker bearing spacer or combination of two spacers as required.
11. After the end play has been adjusted to 0.001-0.005 inch, remove the nut and washer. Insert the O-ring, install the washer and nut, and torque to 350-400 ft-lbs. Install the cotter pin.

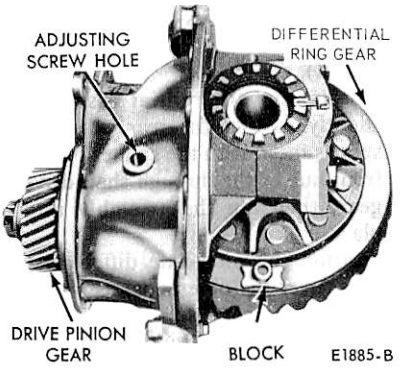

FIG. 10 Installing Thrust Block

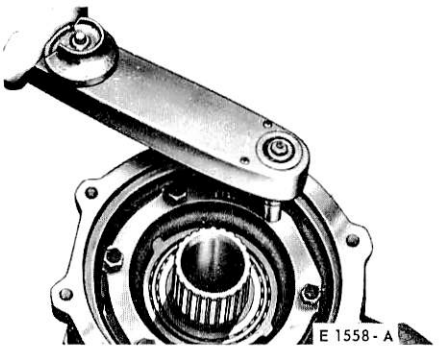

FIG. 11 Torquing Cage Bolts

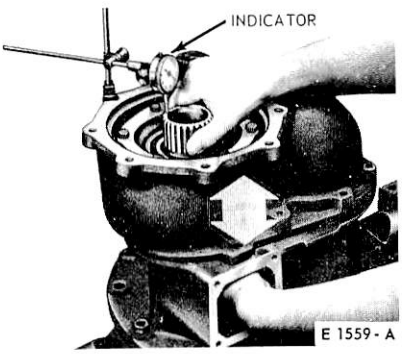

FIG. 12 Checking End Play

THROUGH-SHAFT DRIVE GEAR BEARINGS

Assembly

1. Press the front and rear tapered bearings onto the through-shaft drive gear.
2. If removed in disassembly, press the front bearing cup into the bearing cage.
3. Tap the rear bearing cup into the adapter case.
4. Slide the gear assembly into the adapter case.
5. With the carrier assembly in the stand in an upright position, install a new adapter case gasket and place the adapter case assembly over the carrier (Fig. 1).
6. Install the lock washers and capscrews attaching the adpater case to the carrier and tighten the capscrews evenly and alternately to 60-77 ft-lb. Seat the inner drive gear bearing cup against the carrier face before installing gear, shims, cover and capscrews.
7. Using the original shim pack, install the bearing cage over the through shaft drive gear bearing Fig. 11.
8. Rotate the bearings by hand to seat them in position while installing the capscrews and lock washers that hold the bearing cage to the adapter case. Tighten the capscrews to 27-35 ft-lb torque Fig. 11.
9. Install a dial indicator as shown in Fig. 12.
10. With one hand through the shifter slot and the other on top of the shaft, (Fig. 12) move the gear assembly up and down. The amount of movement should be within the specified amount of endplay (0.001-0.005 inch).

Do not use a bar to move the bearings up and down because this may cock them in position.

11. If the endplay is incorrect, add or subtract shims as required to obtain the correct endplay.
12. Lockwire the capscrews in position.

INTER-AXLE DIFFERENTIAL

Assembly

1. Lubricate the differential case walls and all differential component parts with axle lubricant.
2. Assemble the side gears, spider, pinion gears and thrust washers into the differential rear case half.
3. Align the punch marks, assemble the front case half to the rear case half, and draw the two halves together with the case bolts.
4. Check for free rotation of the gears, and correct if necessary.
5. Torque the differential case bolts to specification, and install the lock wire.

THROUGH-SHAFT

Assembly

1. Install the through-shaft radial bearing into the cage and lock it in

place with the snap ring (Fig. 5).
2. Press the cage and bearing assembly on the rear splined end of the through-shaft so that the inner race of the bearing is firmly seated against the shoulder on the through-shaft. For this operation, use a sleeve that will slip over the shaft and bear against the inner race of the bearing.
3. Install the oil seal in the through-shaft cage with a suitable driver.

ASSEMBLY OF MAJOR COMPONENTS

1. Install the inter-axle differential power divider assembly to the adapter case so that the rear hub of the differential fits over the front hub of the through-shaft drive gear (Fig. 1).
2. Rotate the differential assembly slightly so that the rear side gear splines mesh with the splines on the front hub of the through-shaft drive gear, then tap the assembly into place.
3. Position the inter-axle differential cover over the differential assembly onto the adapter case, and secure the cover to the case with cap screws and lock washers. Torque to specification.
4. Install the spacing washer and the bearing on the differential case front half, and install the bearing snap ring in the differential cover.
5. With suitable driver, install the outer seal in the differential cover.
6. With the carrier case mounted in a stand and in an upright position, install a new adapter case-to-carrier gasket.
7. With a chainfall, lower the inter-axle differential and adapter case assembly onto the carrier case. As the assembly is being positioned, rotate the idler gear shaft so that one shaft flat mates with the cast flat in the carrier.
8. Install the adapter case-to-carrier retaining screws and lock washers, and torque to specification.

① Original production had 9/16 rivets and require 9/16 bolts and nuts for service.
② Current productions has 5/8 rivets and require 5/8 bolts and nuts for service.
Service will no longer stock the original gears incorporating the 9/16 inch holes.
In case of current gear replacement with original cases it will be necessary to line ream the original cases to 625" to accomodate the larger bolts or rivets.
Torques given apply to parts coated with machine oil, for dry or "as rec'd." parts increase torques 10%. For parts coated with multi-purpose gear oil decrease torque 10%. Nuts on studs to use same torque as for driving the studs.

PART 15-60 Drive Shaft — Single Snap Ring Type U-Joint

Applies To All Models Except L-LN-W-9000 Series

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DRIVE SHAFT		SNAP RING TYPE UNIVERSAL JOINT	
Description	60-01	Removal and Installation	60-04
Removal and Installation	60-03	SPECIFICATIONS	60-05

DESCRIPTION

The drive shaft or coupling shaft is composed of the universal joints, connecting shafts, attaching flanges and slip yokes. The number of shafts and universal joints used depends on the vehicle wheelbase. The shorter wheelbase vehicles (F-100 117 inch wheelbase and the E-100-E-300) use a one piece drive shaft as shown in Fig. 1. The longer wheelbase vehicles use a coupling shaft in conjunction with a drive shaft (Fig. 2 and 3).

The longer wheelbase vehicles are equipped with one or more coupling shafts, which extend from the transmission to rubber bushed center support bearings, and a drive shaft which extends from the center support to the rear axle.

On Econoline models, with 123.5 inch wheelbase and all models with automatic transmission the shaft is attached to the extension housing by a fixed yoke. Splines in the yoke and on the shaft permit the shaft to move forward and rearward as the rear axle moves up and down.

On 105.5 inch wheelbase vehicles except with automatic transmission a conventional slip-yoke type drive shaft is used (Fig. 1). The yoke is splined directly to the extension housing and slides forward and rearward in the extension housing as the axle moves up and down.

If a single drive shaft is used, the slip joint is at the transmission end of shaft; if two or more shafts are used, the slip joint is at forward end of the rear shaft.

Some vehicle universal joint spiders and sliding splines are equipped with lubrication fittings. These spiders and splines should be lubricated periodically using lithium grease (C1AZ-19590-B).

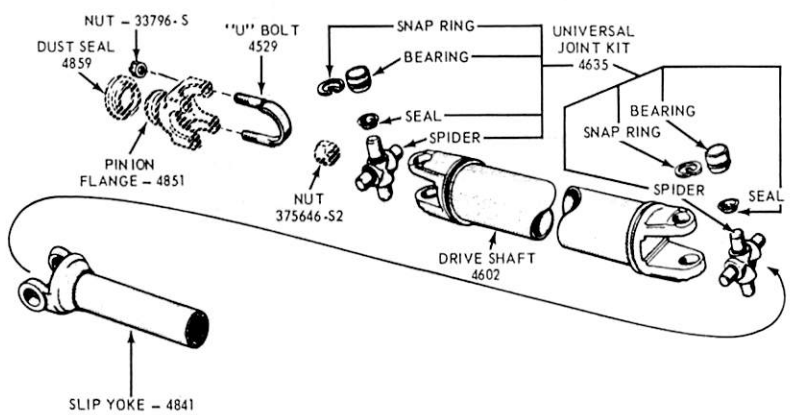

FIG. 1 Drive shaft Components (F-100 117 inch wheelbase and E-100, E-300) Slip-Yoke Design.

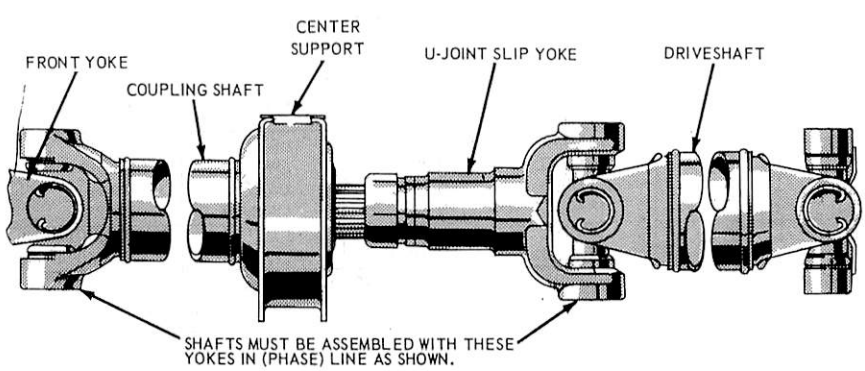

FIG. 2 Drive Shaft Components—132 and 140 Inch Wheelbase Manual Transmission

The majority of vehicles are equipped with center support bearings that are prelubricated and sealed for the life of the bearing. However, some vehicles have center support bearings equipped with lubrication fittings which should be lubricated periodically using lithium grease (C1AZ-19590-B).

All universal joints are of the needle-bearing type. The universal joint bearings are retained on the universal joint spiders by snap rings or U-bolts.

Drive shafts and coupling shafts are balanced; therefore, if the vehicle is to be undercoated, cover the drive shaft to prevent getting undercoating material on the shaft.

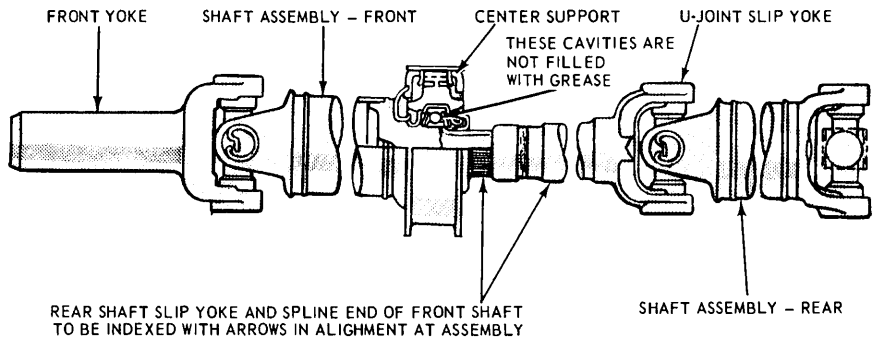

FIG. 3 Coupling Shaft and Center Support Bearing Automatic Transmission (F100-350—except F350 with FMX Transmission)

ADJUSTMENTS

DRIVESHAFT BALANCING

1. Raise the vehicle on a twin-post hoist so that both the front and rear axles are safely supported with all wheels free to rotate.
2. With the transmission in gear (include transfer unit on 4x4 type vehicles) increase vehicle speed to maximum vibration lever. Note and record the speedometer speed of this vibration period which will be used as a baseline level.

Two people are required to perform this operation; one in the vehicle, and one under the vehicle making adjustments.

3. Check attachment of all universal joint bearing caps of driveshaft or coupling shafts to transmission yoke, front or rear axle pinion yokes and all transfer unit drive yokes for improper installation or damaged universal joint bearing cap locating lugs. All yokes indicating worn, shaved, or damaged locating lugs must be replaced.
4. Check driveshaft and coupling shaft for correct phasing. If necessary, rephase driveshaft and coupling shaft as shown in Group 15-62 of this Manual.
5. With transmission (and transfer unit) in gear, run vehicle with the driveshaft and coupling shaft rotating at a speedometer speed of 40-50 mph, carefully bring a crayon, piece of chalk, or colored pencil up until it just barely contacts the rear end, center, and front end of the driveshaft (refer to Figure 4). The chalk marks will indicate the heavy side of the driveshaft. Use caution when checking driveshaft near the balance weights to prevent injury to the hands.

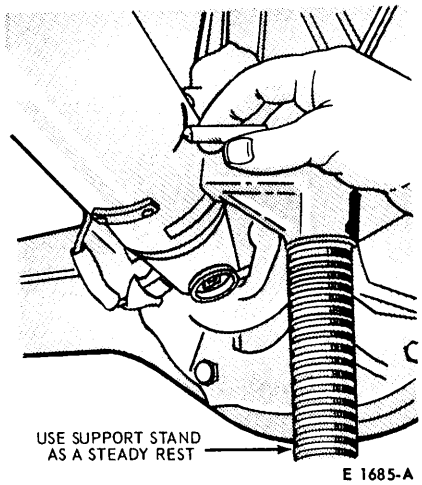

FIG. 4 Marking Drive Shaft

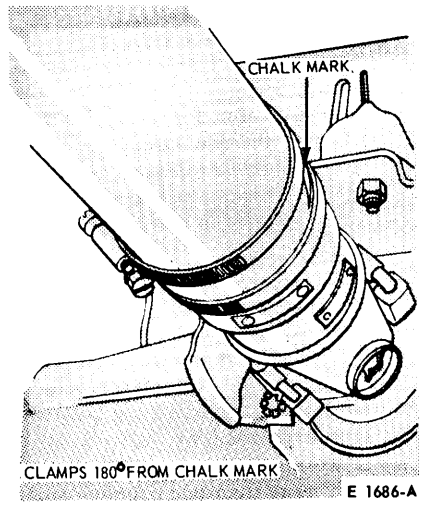

FIG. 5 Installing Clamps

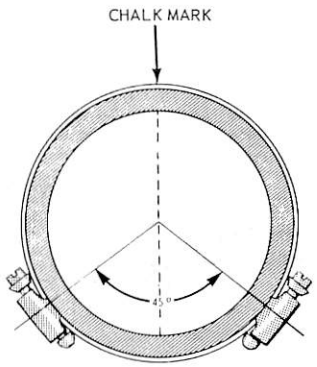
6. Install two screw-type hose clamps on the driveshaft so that the heads are located 180 degrees from the chalk mark, starting at the pinion yoke end of the driveshaft. Tighten clamps (refer to Figure 5).
7. Run the vehicle up to the baseline speed. If vibration is still evidenced, rotate clamps approximately 45 degrees away from each other and test for correction of vibration. (Refer to figure 6).
8. If necessary, continue to rotate the clamps apart in smaller increments until vibration is eliminated or begins to be reduced.
9. If the vibration is not completely eliminated, repeat the above procedure and balance the front end of the driveshaft, checking for elimination or reduction in the vibration level.
10. To completely eliminate the driveline vibration, it may be necessary to balance the coupling shaft, following the same procedure indicated above. To prevent overheating, do not run the vehicle on the hoist for an extended period.
11. Remove the vehicle from the hoist and road test.



E 1687-A

FIG. 6 Rotating Clamps

REMOVAL AND INSTALLATION

DRIVE SHAFT (MANUAL TRANSMISSION)

Removal

1. Disconnect the drive shaft from the flange at the rear axle.
2. If working on a 117 inch wheel base vehicle. disconnect the drive shaft rear flange from the flange at the rear axle.
3. If working on a vehicle equipped with a coupling shaft, slide the drive shaft off the coupling shaft splines.
4. Working from the center support nearest to the rear of the vehicle, remove the two attaching bolts and support the bearing.
5. If working on a vehicle equipped with more than one coupling shaft, disconnect the rear shaft from the front one.
6. Remove the remaining center support attaching bolts and support the bearing.
7. Remove the nuts that attach the coupling shaft flange to the transmission and remove the shaft and center bearing as an assembly.
8. Thoroughly clean old grease and dirt from the drive shaft splines and then check the splines for wear, warpage, and cracks. If the shaft is worn, warped, or cracked, replace it.

Using a suitable cleaning fluid, clean all dirt from the slip yoke, slip yoke splines, and shaft splines. Carefully inspect the slip yoke splines for wear or evidence of twisting. Check the clearance between the slip yoke splines and the shaft splines.

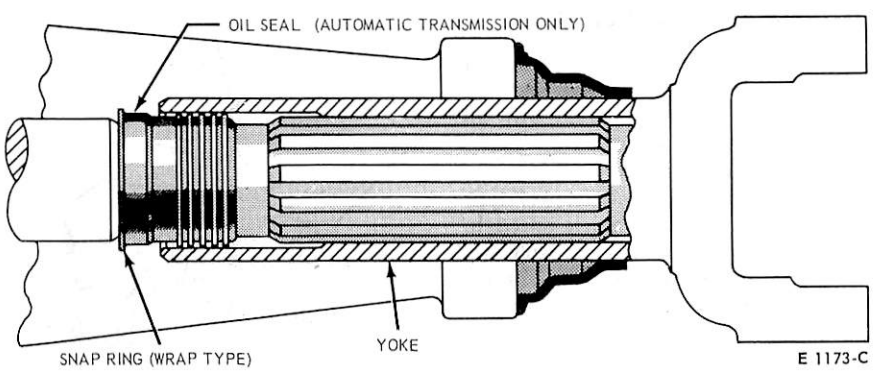


FIG. 7 Output Shaft Spline Seals

Wash all parts except the sealed ball bearing and rubber cushion in suitable cleaning fluid. **Do not immerse the sealed bearing in cleaning fluid. Wipe the bearing and cushion clean with a cloth dampened with cleaning fluid.**

Check the bearing for wear or rough action by rotating the inner race while holding the outer race. If wear or roughness is evident, replace the bearing.

Examine the rubber cushion for evidence of hardening, cracking, or deterioration. Replace it if damaged in any way.

Grease retainers and slingers are serviced only as a part of the bearing assembly.

Installation

1. Connect the front flange or joint of the drive shaft or coupling shaft to the flange on the transmission. Torque the nuts to specifications.
2. Secure the center bearing to the frame bracket with the center support and attaching bolts. Torque the bolts to specification.
3. If working on a truck with more than one coupling shaft, connect the rear shaft to the forward one, then install the remaining center support.
4. Connect the rear universal to the rear axle flange and torque the nuts or bolts to specifications. Be sure all drive shaft and coupling shaft yokes are properly in phase.

DRIVE SHAFT (AUTOMATIC TRANSMISSION)

Removal

1. To maintain drive line balance, mark the relationship of the rear drive shaft yoke and the drive pinion flange of the axle (if the yellow alignment marks are not visible)

with the shaft so that they may be installed in their original positions.

2. Disconnect the rear U-joint from the companion flange. Wrap tape around the loose bearing caps to prevent them from falling off the spider. Pull the drive shaft toward the rear of the vehicle until the slip yoke clears the transmission extension housing and the seal. Install the appropriate tool in the extension housing to prevent lubricant leakage.

Installation

1. If either the rubber seal on the output shaft or the seal in the end of the transmission extension housing is damaged in any manner, replace the seal or seals as required (Fig. 7). Also, if the lugs on the axle pinion flange are shaved or distorted so that the bearings slide, replace the flange.
2. Lubricate the yoke spline with MIC75B lubricant. This spline is sealed so that the transmission fluid does not wash away the spline lubricant (Fig. 7). Remove the tool from the extension housing. Install the yoke on the transmission output shaft. Do not allow the yoke assembly to bottom on the output shaft with excessive force.

Install the drive shaft so that the index marks or the yellow mark (if visible) on the yoke (light side) is in line with the yellow mark on the companion flange. This prevents vibration which occurs when the balance of the shaft and balance of the axle pinion flange become additive instead of neutralizing. If a vibration exists, the drive shaft should be disconnected from the axle, rotated 180 degrees and reinstalled.

3. Install the U-bolts and nuts that attach the U-joints to the drive pinion flange. Torque the U-bolt nuts to 8-15 ft-lbs.

SNAP RING TYPE UNIVERSAL JOINT

Removal

1. Place the drive shaft in a vise being careful not to damage it.
2. Remove the snap rings that retain the bearings in the yoke and in the drive shaft or coupling shaft.
3. Position the tool shown in Fig. 8 on the shaft and press the bearing out of the yoke. If the bearing cannot be pressed all the way out of the flange, remove it with vise grip or channel lock pliers.
4. Reposition the tool to press on the spider to remove the bearing from the opposite side of the flange.
5. Remove the flange from the spider.
6. Remove the bearings and spider from the drive shaft or coupling shaft in the same manner.
7. Clean all foreign matter from the yoke area at each end of the drive shaft.

Wash all parts in cleaning fluid. Make sure the lubricant passages in the journal cross are clean. Check the needle bearings and journals for evidence of wear or excessive heat.

Soak the needle bearing assemblies in a commercial cleaning fluid to soften particles of hardened grease. Then, wash these parts in cleaning fluid using a stiff brush if necessary to remove all old lubricant. Check each bearing for missing rollers.

After the needle bearing assemblies are thoroughly clean, apply clean lubricant to the rollers. Rotate them on the trunnion of the journal to check wear. Fill the journal passages with C1AZ-19590-B (ESA-M1C75-B) lubricant and fill the bearings approximately 1/3 full of C1AZ-19590-B (ESA-M1C75-B) lubricant before reassembly.

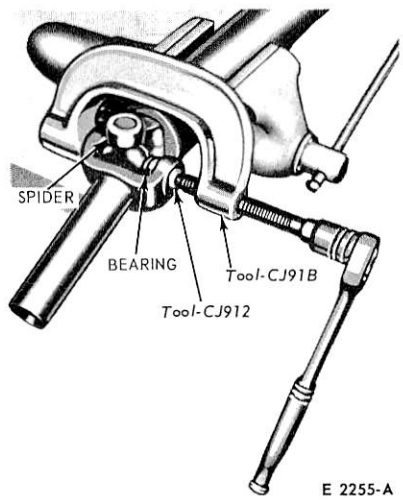

FIG. 8 Removing Universal Joint Bearing—Typical

Installation

1. Start a new bearing into the yoke at the rear of the drive shaft.
2. Position the spider in the rear yoke and press the bearing 1/4 inch below the surface (Fig. 9).
3. Remove the tool and install a new snap ring.
4. Start a new bearing into the opposite side of the yoke.
5. Install the tool and press on the bearing until the opposite bearing contacts the snap ring.
6. Remove the tool and install a new snap ring.
7. Reposition the drive shaft or coupling shaft and install the new spider and two new bearings in the front yoke in the same manner as the rear yoke.
8. Position the flange on the spider and install two new bearings and snap rings.
9. Check the joint for freedom of movement. If a bind has resulted from misalignment during the foregoing procedures, tap the ears of the drive shaft sharply to relieve the bind. Do not install the drive shaft unless the universal joints are free of bind.
10. Lubricate the universal joints with long life lithium grease C1AZ-19590-B (ESA-M1C75-B).

CE2238-C

DESCRIPTION

The drive shaft or coupling shaft is composed of the universal joints, connecting shafts, and the attaching flanges. The number of shafts and universal joints used depends on the vehicle wheelbase.

All the vehicle universal joint spiders and sliding splines are equipped with lubrication fittings. These spiders and splines should be lubricated periodically using lithium grease ESA-M1C75-B

The majority of vehicles are equipped with center support bearings that are prelubricated and sealed for the life of the bearing. However, some vehicles have center support bearings equipped with lubrication fittings which should be lubricated periodically using lithium grease (C1AZ-19590-B).

Trucks equipped with an auxiliary transmission have a transmission to auxiliary transmission drive shaft to transmit the power from the conventional transmission to the auxiliary transmission. This assembly consists of two close-coupled universal joints (Fig. 1). All universal joints are of the needle-bearing type. The universal joint bearings are retained on the universal joint spiders by snap rings or U-bolts, or by bearing caps and bolts.

Drive shafts and coupling shafts are balanced; therefore, if the vehicle is to be undercoated, cover the drive shaft to prevent getting undercoating material on the shaft.

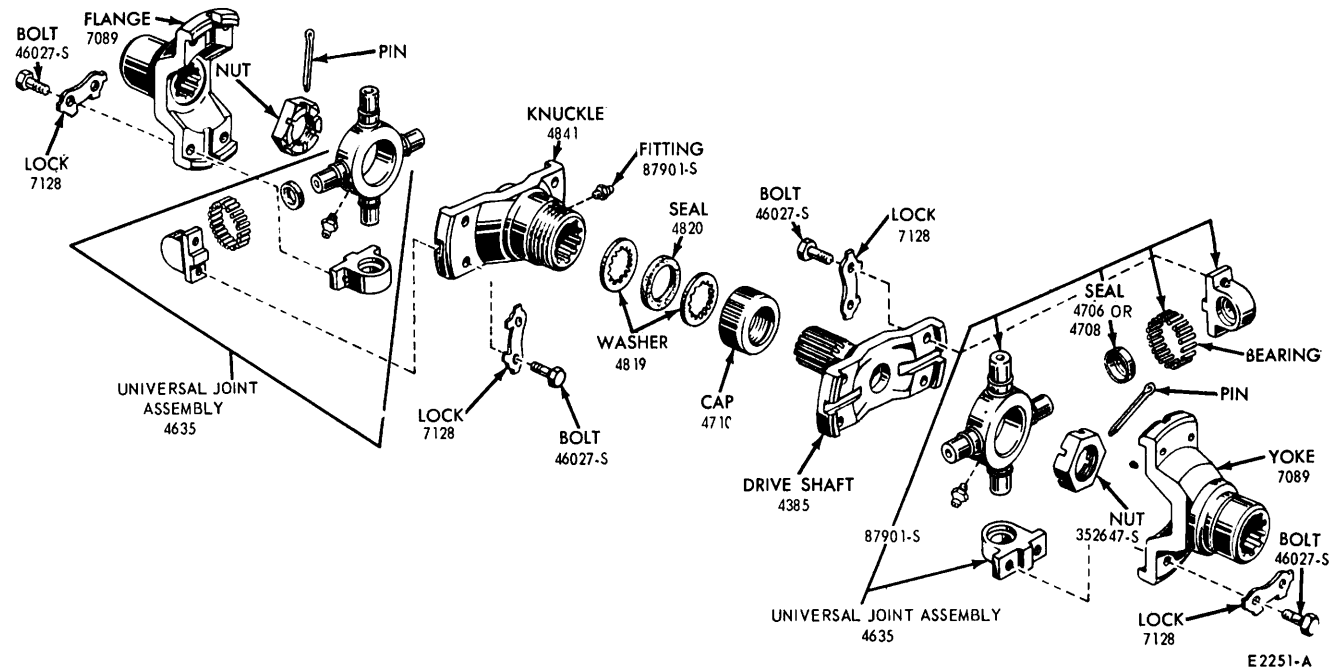

FIG. 1 Transmission-To-Auxiliary Universal Joints

ADJUSTMENTS

U-JOINT PHASING

When U-joint yokes are assembled to their shafts in the same plane, they are in phase (Fig. 2). When they are assembled to the shafts in different planes, they are out of phase (Fig. 3).

To obtain vibration-free operation, check and correct as necessary according to the following specifications (Fig. 2).

1. The U-joints between the main and auxiliary transmission must be in phase (Fig. 2).
2. The main drive shaft U-joint flanges are to be in phase as shown in Fig. 2.
3. Tandems which require a specific inter-axle drive shaft phasing, are identified by arrows which are stamped on slip yoke and stud end. The arrows must be in line as shown in fig. 3 (Eaton 30D-2 or 3 speed, Eaton 34D-2 or 3 speed, and Eaton 42D).

DRIVE SHAFT ALIGNMENT

To properly adjust drive line angles, a spirit level protractor is necessary. When angles are read from the 0 degree mark (for example, measuring inter-axle shaft angle) record and use the angle shown on the protractor since the 90 degree marks must be treated as 0 degree. For example, a protractor reading of 85 degrees is actually 5 degrees. See Fig. 4 or 5.

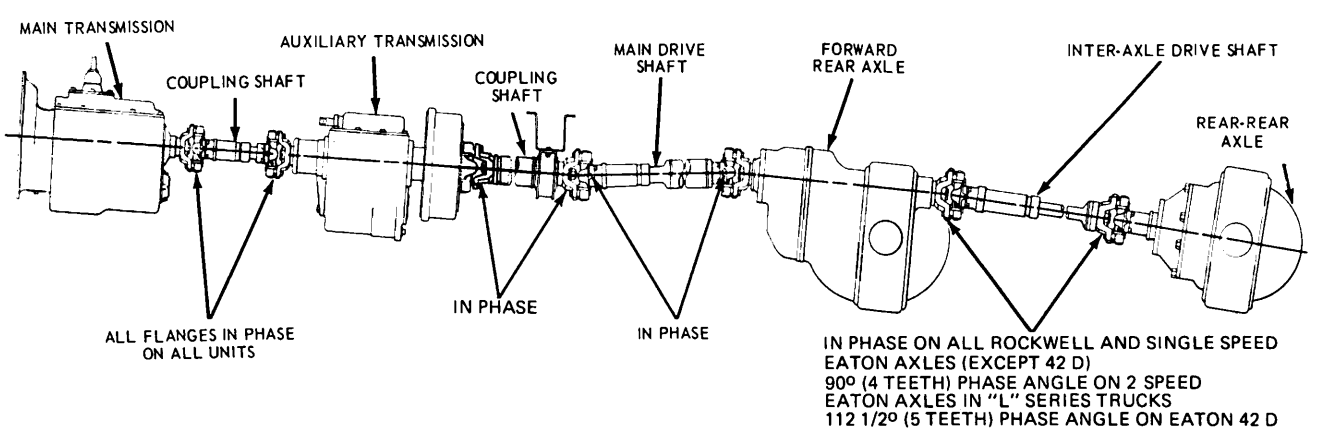

FIG. 2 Typical Tandem Axle Drive Shaft

All angles should be read within 1/4 degrees (15 minutes) and they should be measured with the protractor held plumb on a clean, flat surface.

The following procedures should be followed to check drive shaft angles and adjust as required:

1. Inflate all tires to the pressure at which they normally operate.
2. Park the empty vehicle on a surface which is fairly level — both front and rear and side to side. The truck must be in its normal operating position. Do not attempt to level the truck by jacking up the front or rear axles of the frame.
3. Check and record the angle of the engine and main transmission (Angle 1). This reading can be taken at the rear of the main transmission to the left of the bearing retainer or output flange. Lock the protractor at this reading.
4. **Remove the drive shaft or coupling shaft from the auxiliary transmission output flange.** Place the locked protractor on the output flange of the auxiliary transmission (Fig. 6) and adjust the auxiliary transmission as necessary to center the bubble. Loosen the front trunnion clamping bolt on the auxiliary transmission before attempting to adjust the angle of the auxiliary transmission. The adjusting bolts should be adjusted evenly so that the same amount of thread is showing on both bolts. This will put the angle of the auxiliary transmission (Angle 3) the same as the main transmission (Angle 1) (Fig. 7). The drive shaft or coupling shaft should be reinstalled **after** all driveline angles have been checked or adjusted.
5. Check and record the angle of the shaft between the main and auxiliary transmission (Angle 2). Take this reading by placing the protractor on the inter-transmission shaft. Angle 2 must be 1 degree less than Angle 1, plus or minus 1/2 degree. Adjust the engine or the auxiliary transmission to bring the inter-transmission shaft 1 degree less than Angle 1, plus or minus 1/2 degree, keeping the main and auxiliary transmissions parallel. Tighten the front clamping bolts on the auxiliary transmission.
6. From the chart in Fig. 8, add the difference angle to angle 1 recorded in step 3 above. Set the bubble protractor to this angle (Angle 1 plus difference angle) and reposition the forward rear axle as required to obtain this angle. Example: 300D tandem, Hendrickson rubber suspension.

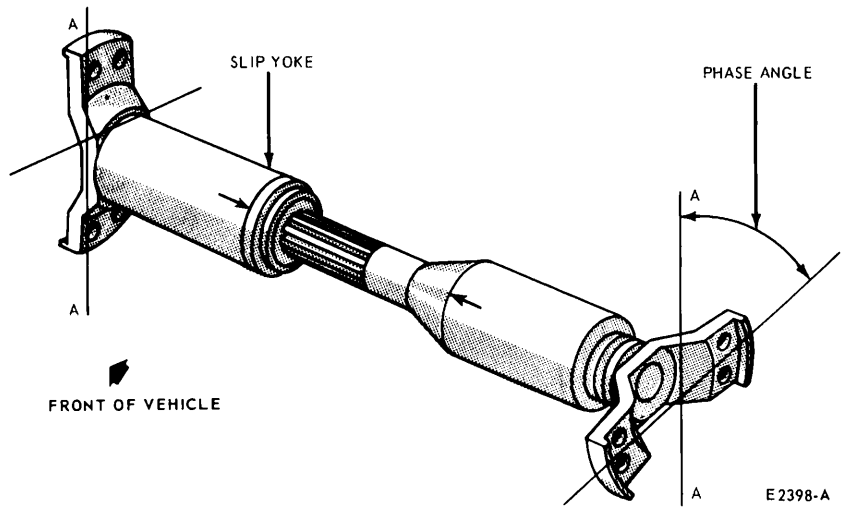

FIG. 3 Inter-Axle Phasing

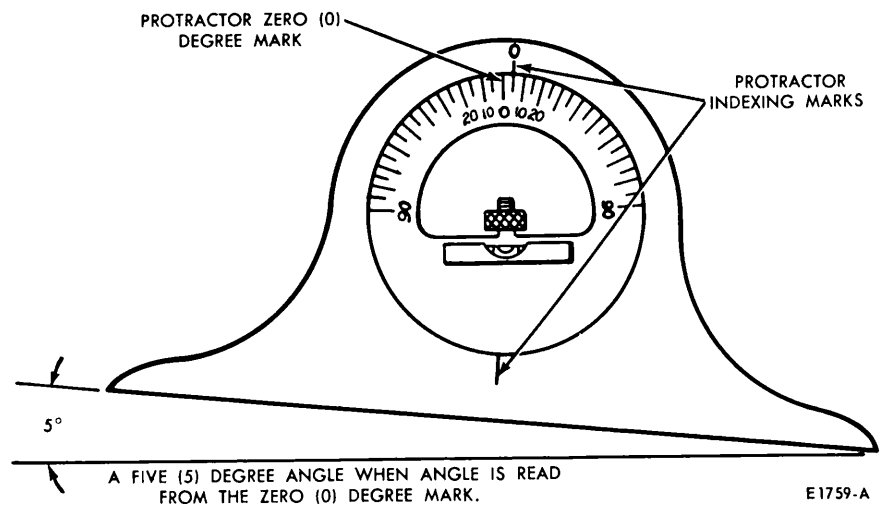

FIG. 4 Drive Shaft angle Read From Zero Mark — Horizontal Position

a. Vehicle to be empty (unloaded) and on reasonable even surface.
b. From the chart; forward rear axle is 1/2 degree more than main transmission angle. Rear joint angle G is 5 1/4 degree.
c. Main transmission angle is measured and found to be 5 1/2 degrees.
d. Set bubble protractor at 5 1/2; **1/2 equals 6 degrees and adjust forward rear axle to obtain this angle.**
e. Measure inter-axle shaft angle 5 and rear angle 6. Angle 5 must be greater than angle 6 by 5 1/2 degrees. Adjust rear axle to obtain this angle.

7. For axles listed under note (1) in Fig. 8, angle 5 must be greater than angle 6 (Fig. 9 illustrates this). For axles listed under note (2), angle 6 must be greater than angle 5 (Fig. 10 illustrates this). The difference of these two angles is equal to angle G.

Torque Arm Shimming

The adding or removing of shims from the forward rear axle torque arm will change angle 4. The 1/4 inch shims will change this angle by approximately 3/4 degree. The addition or removal of a 1/2 inch shim from rear axle torque arm will change angle G approximately 1 1/4 degree.

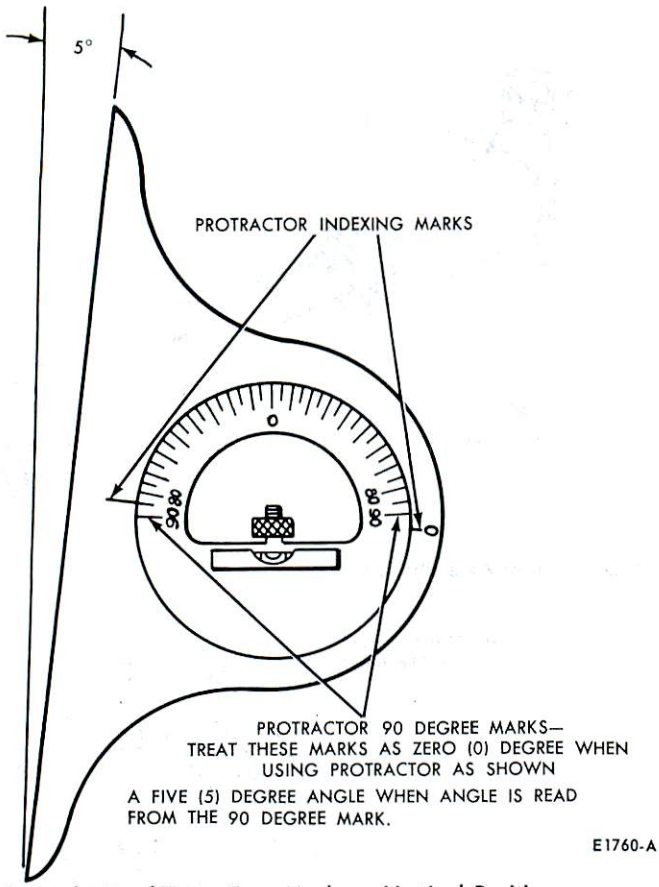

FIG. 5 Drive Shaft Angle Read From Zero Mark — Vertical Position

REMOVAL AND INSTALLATION

DRIVE SHAFT

Removal

1. Disconnect the drive shaft from the flange at the rear axle.
2. If working on a vehicle equipped with a coupling shaft, slide the drive shaft off the coupling shaft splines. On certain Mechanics, Rockwell and heavy duty Spicer assemblies remove the attaching bolts.
3. Working from the center support nearest to the rear of the vehicle, remove the two attaching bolts and support the bearing. Different types of support brackets are used. Some have elongated mounting holes. This permits close adjustment (medium vehicles).
4. If working on a vehicle equipped with more than one coupling shaft, disconnect the rear shaft from the front one.
5. Remove the remaining center support attaching bolts and support the bearing.
6. Remove the nuts that attach the coupling shaft flange to the transmission and remove the shaft and center bearing as an assembly.
7. Thoroughly clean old grease and dirt from the drive shaft splines and then check the splines for wear, warpage, and cracks. If the shaft is worn, warped, or cracked, replace it.

Using a suitable cleaning fluid, clean all dirt from the slip yoke, slip yoke splines, and shaft splines. Carefully inspect the slip yoke splines for wear or evidence of twisting. Check the clearance between the slip yoke splines and the shaft splines.

Wash all parts except the sealed ball bearing and rubber cushion in suitable cleaning fluid. **Do not immerse the sealed bearing in cleaning fluid.** Wipe the bearing and cushion clean with a cloth dampened with cleaning fluid.

Check the bearing for wear or rough action by rotating the inner race while holding the outer race. If wear or roughness is evident, replace the bearing.

Examine the rubber cushion for evidence of hardening, cracking, or deterioration. Replace it if damaged in any way.

Grease retainers and slingers are serviced only as a part of the bearing assembly.

Installation

1. Connect the front flange or joint of the drive shaft or coupling shaft to the flange on the transmission. Torque the nuts to specifications.
2. Secure the center bearing to the frame bracket with the center support and attaching bolts. Note that L-Series vehicles use adjustable 2-piece center bearing support brackets. Torque the bolts to specification.
3. If working on a truck with more than one coupling shaft, connect the rear shaft to the forward one, then install the remaining center support. All splines should be lubricated with ESA-M1C75-B
4. Connect the rear universal to the rear axle flange and torque the nuts or bolts to specifications. Be sure all drive shaft and coupling shaft yokes are properly in phase.

BEARING CAP AND BOLT TYPE UNIVERSAL JOINT (EXCEPT L-LN-W, AND 9000 SERIES)

Removal

1. Remove the capscrews which attach the bearing caps to the universal joint flange and yoke. Remove the bearing caps and bearings from the spider.
2. Remove the grease seals, and retainers, from the spider.

Wash all parts in cleaning fluid. Make sure the lubricant passages in the journal cross are clean. Check the needle bearings and journals for evidence of wear or excessive heat.

3. Soak the needle bearings and cages in a commercial cleaning fluid to soften particles of hardened grease. Then, wash these parts in cleaning fluid using a stiff brush if necessary to remove all old lubricant. Check each bearing for missing rollers.
4. After the needle bearing assemblies are thoroughly clean, apply clean lubricant to the rollers. Rotate them on the trunnion of the journal to check wear. Fill the journal passages with ESA-M1C75-B lubricant and fill the bearings approximately 1/3 full of ESA-M1C75-B lubricant before reassembly.

Installation

1. To install, pack the recess in the spider with the recommended lubricant (ESA-M1C75-B).
2. Install the grease seals on the spider.
3. Position the needle bearings in the bearing caps, then position the caps on the spider. Place the spider on the yokes, and then install the bearing caps. Torque the bolts to specifications.
4. Secure the locks to the yokes with capscrews.
5. Lubricate the universal joints with long life lithium grease (C1AZ-19590-B).

BOLTED END CAP TYPE UNIVERSAL JOINT (L-LN-W, AND 9000 SERIES)

Removal

1. Bend the tangs of the lock plates away from the capscrews.
2. Remove the capscrews and lock plates that attach the bearing caps to the universal joint flange. Remove the bearing caps and bearings from the flange and spider (Fig. 11).

If the bearing and cap are integral, tap the bearing cap lightly clockwise and then counter clockwise and with a screwdriver, pry under first one end of the bearing cap and then the other until the bearing comes out of the yoke. Turn the joint over and remove the opposite bearing in the same manner. If the bearing cap and bearing are separate, the bearing cap will come off with a light tap.

Remove the bearings by first tapping with a soft round drift on the exposed face of one bearing until the opposite bearing comes out. Turn the joint over and tap the exposed end of the journal cross pin until the opposite bearing is free.

3. Remove the spider. All burrs on the bearing cap or yoke must be removed before placing spider in the yoke.
4. Wash all parts in cleaning fluid. Make sure the lubricant passages in the journal cross are clean. Check the needle bearings and journals for evicence of wear or excessive heat.

Soak the needle bearings and cages in a commercial cleaning fluid to soften particles of hardened grease. Then, wash these parts in cleaning fluid using a stiff brush if necessary to remove all old lubricant. Check each bearing for missing rollers.

After the needle bearing assemblies are thoroughly clean, apply clean lubricant to the rollers. Rotate them on the trunnion of the journal to check wear. Fill the journal passages with ESA-M1C75-B lubricant and fill the bearings approximately 1/3 full of ESA-M1C75-B lubricant before reassembly.

Installation

1. Position the needle bearings in the bearing caps.
2. Position the spider in the flange and install the bearing caps through the yoke and onto the spider. Press or tap with a soft drift.
3. Position the lock plates to the bearing caps and secure them with the capscrews. Torque the screws to specifications. Bend the tangs of the locks up against the capscrews.
4. Lubricate the universal joints with long life lithium grease ESA-M1C75-B.

TRANSMISSION TO AUXILIARY TRANSMISSION UNIVERSAL JOINTS

Removal

1. To replace the transmission to auxiliary transmission input shaft U-joint assembly (Fig. 1), remove the universal bearing cap bolts from the auxiliary transmission input shaft yoke and the transmission output shaft yoke.
2. After the universal joint assembly has been removed from the truck, separate the two universal joints by loosening and removing the dust cap, washers, and seal from the U-

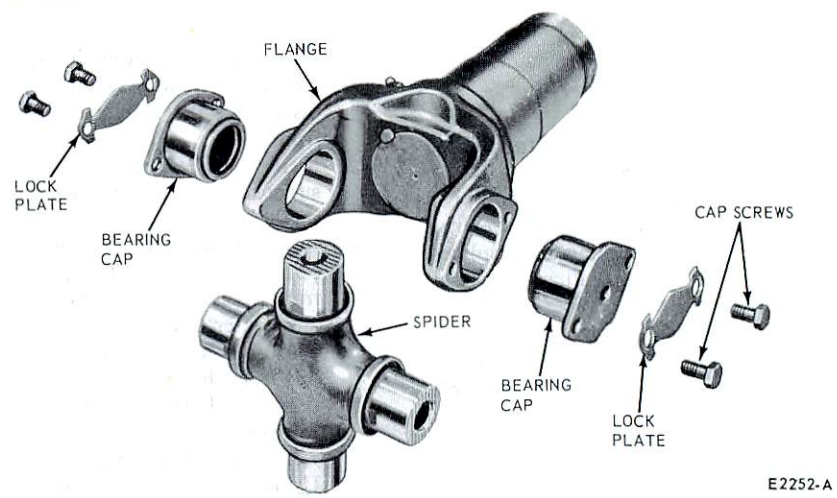

FIG. 11 Bolted End Cap Type UniversalJoint—Disassembled

joint knuckles. Pull the assemblies apart.

3. Remove the bearing caps and spiders from their respective yokes.

Installation

1. Clean and inspect the spiders, bearings, and shields. Replace with new parts as required, and assemble the spiders onto the U-joint knuckle and coupling shaft respectively.
2. Install the dust cap, washers, and seal over the splined end of the drive shaft. Install the drive shaft into the knuckle so that the universal joint spiders are on the same plane. Tighten the dust cap on the knuckle until it is snug.
3. Install the universal joint with the slip yoke toward the front of the vehicle. Be sure the companion flanges on the transmissions are on the same plane. Attach the spider bearing caps to the respective flanges with bolts. Torque the bolts to specifications.
4. Lubricate the universal joints with long life lithium grease (C1AZ-19590-B).

PART 15-66 Drive Shaft-Double Cardan Type U-Joints

Applies to Bronco Only

COMPONENT INDEX	Page	COMPONENT INDEX	Page
DOUBLE CARDAN JOINT		DRIVE SHAFT - Continued	
Assembly	66-02	Removal and Installation	66-01
Disassembly	66-02		
DRIVE SHAFT		SPECIFICATIONS	66-03
Description	66-01		

DESCRIPTION

The Bronco drive shaft assemblies are of the double cardan type which incorporates two universal joints, a centering socket yoke, and a center yoke at the transfer case end of each shaft (Fig. 1). A single universal joint is used at the axle end of the shafts.

The universal joint spiders and sliding splines are equipped with lubrication fittings. These spiders and splines should be lubricated periodically using lithium grease (C1AZ-19590-B).

All drive shafts are balanced. Therefore, if the vehicle is to be undercoated, cover the drive shaft to prevent getting undercoating material on the shaft.

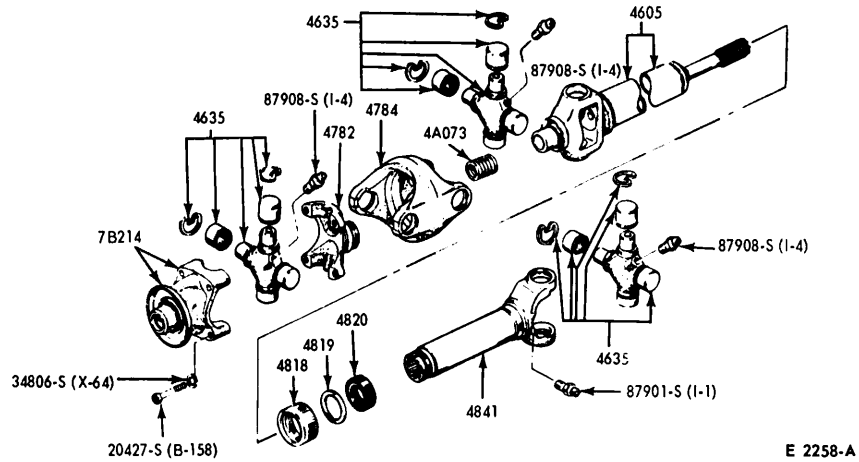

FIG. 1 Drive Shaft Disassembled — Bronco

REMOVAL AND INSTALLATION

DRIVE SHAFT

Removal

1. To remove the rear drive shaft, disconnect the double cardan joint from the flange at the transfer case and the single U-joint from the flange at the rear axle. Remove the drive shaft.
2. To remove the front drive shaft, disconnect the double cardan joint from the flange at the transfer case and the single U-joint from the flange at the front axle. Remove the drive shaft.

Installation

1. To install the front drive shaft, position the single U-joint end of the drive to the front axle and install the U-bolts and nuts.
2. Position the double cardan joint to the transfer case and install the four bolts and lock washers.
3. Torque all the bolts and nuts to specifications.
4. To install the rear drive shaft, position the single U-joint end of the drive shaft to the rear axle and install the U-bolts and nuts.
5. Position the double cardan joint to the transfer case and install the four bolts and lock washers.
6. Torque all the bolts and nuts to specifications.

DISASSEMBLY AND ASSEMBLY

DOUBLE CARDAN JOINT

Disassembly

1. Mark the position of the spiders, the center yoke, and the centering socket yoke as related to the stud yoke which is welded to the front of the drive shaft tube. **The spiders must be assembled with the bosses in their original position to provide proper clearance.**
2. Remove the snap rings that secure the bearings in the front of the center yoke.
3. Position the tool as shown in Fig. 2. Thread the tool clockwise until the bearing protrudes approximately 3/8 inch out of the yoke.

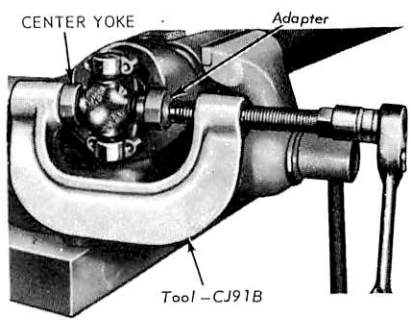

FIG. 2 Partially Pressing Bearing From Center Yoke

4. Remove the drive shaft from the vise.
5. Tighten the bearings in the vise and drive on the center yoke as shown in Fig. 3 to free it from the bearing.

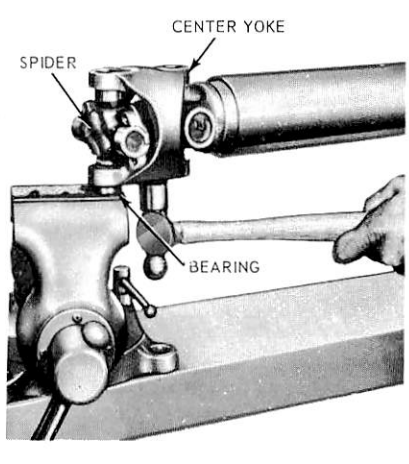

FIG. 3 Removing Bearing From Center Yoke

6. Lift the two bearings (Fig. 4) from the spider at this time.

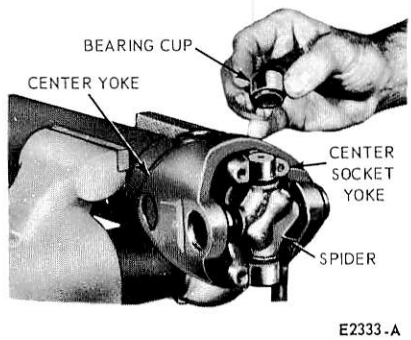

FIG. 4 Removing Bearing Cup From Centering Yoke Socket

7. Reposition the tool on the yoke and move the remaining bearing in the opposite direction so that it protrudes approximately 3/8 inch out of the yoke.
8. Grip the bearing in a vise. Drive on the center yoke to free it from the bearing (Fig. 3).
9. Remove the spider from the center yoke.
10. Pull the centering socket yoke off the center stud (Fig. 5). Remove the rubber seal from the centering ball stud.

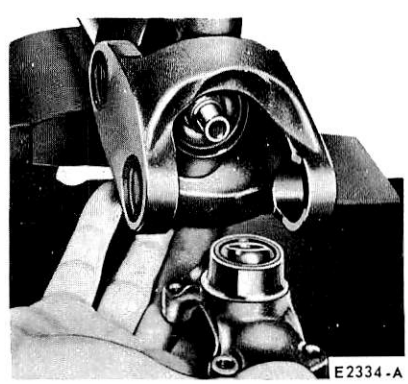

FIG. 5 Removing Center Socket Yoke

11. Remove the snap rings from the center yoke and from the drive shaft yoke.
12. Position the tool on the drive shaft yoke (Fig. 6) and press the bearing outward until the inside of the center yoke almost contacts the slinger ring at the front of the drive shaft yoke. Pressing beyond this point can distort the slinger ring. The arrow in Fig. 7 illustrates the interference point.
13. Clamp the exposed end of the bearing in a vise and drive on the center yoke with a soft-faced hammer to free it from the bearing.
14. Reposition the tool and press on the spider to remove the opposite bearing.
15. Remove the center yoke from the spider.
16. Remove the spider from the drive shaft yoke in the same manner.
17. Clean all serviceable parts in cleaning solvent. If using a repair kit, install all of the parts supplied in the kit. If the drive shaft is damaged, replace the complete shaft to be assured of a balanced assembly.

Assembly

1. To assemble the double cardan joints, position the spider in the drive shaft yoke. Make sure the spider bosses (or lubrication plugs on kits) will be in the same position as originally installed. Press in the bearing cups. Install the snap rings.
2. Position the center yoke over the spider ends and press in the bearing cups. Install the snap rings.
3. Install a new seal on the centering ball stud. Position the centering socket yoke on the stud.
4. Place the front spider in the center yoke. Make sure the spider bosses (or lubrication plugs on kits) are properly positioned. Press in the bearing cups and install the snap rings.
5. Apply pressure on the centering socket yoke and install the remaining bearing cup.
6. On kits, remove the plug from each spider and lubricate the universal joints. Reinstall the plug in each spider.

Cleaning and Inspection	01-04	SPECIFICATIONS	01-04

ADJUSTMENTS

FLYWHEEL HOUSING ALIGNMENT

Alignment of the flywheel housing bore and rear face with the engine should be checked as a possible cause of any of the following troubles: excessive transmission gear wear, transmission jumping out of gear, especially third gear, clutch pedal vibration or scrubby pedal feel, drive line vibration, excessive pilot bushing wear, or excessive clutch spin time. Whenever any of the above problems are identified, the clutch housing should be given a complete inspection.

INSEPCTION

All Engines

1. With the clutch release bearing removed, install the indicator pilot tool (T57T-66399-A) as shown in Fig. 1.
2. Clean the faces of the flywheel housing bolt bosses, and remove all burrs, nicks, and paint from the mating surfaces.
3. Install the dial indicator on the pilot and adjust the holder so the button will contact a circumference just inside of the transmission mounting holes on the machined surface.
4. Push the flywheel forward to remove crankshaft end play. Set the dial indicator face to read zero.
5. Remove the spark plugs to relieve compression.
6. Rotate the engine crankshaft through one revolution. The crankshaft must be held in the forward position while rotating it. The indicator reading must return to zero after one revolution to insure that no end play has affected the reading. Note the indicator reading (Fig. 1). The maximum misalignment of the transmission mounting face with the C/L of the crankshaft shall be 0.001 total indicator reading (T.I.R.) per inch of checking radius.
7. Position the dial indicator to check bore alignment (Fig. 1). the bore must be clean and free of burrs, nicks, and paint.
8. Rotate the crankshaft through one revolution and note the indicator reading (Fig. 1). The maximum misalignment of the clutch housing bore with the C/L of the crankshaft shall be 0.001 total indicator reading (T.I.R.) per inch of transmission shaft penetration in the clutch housing bore.

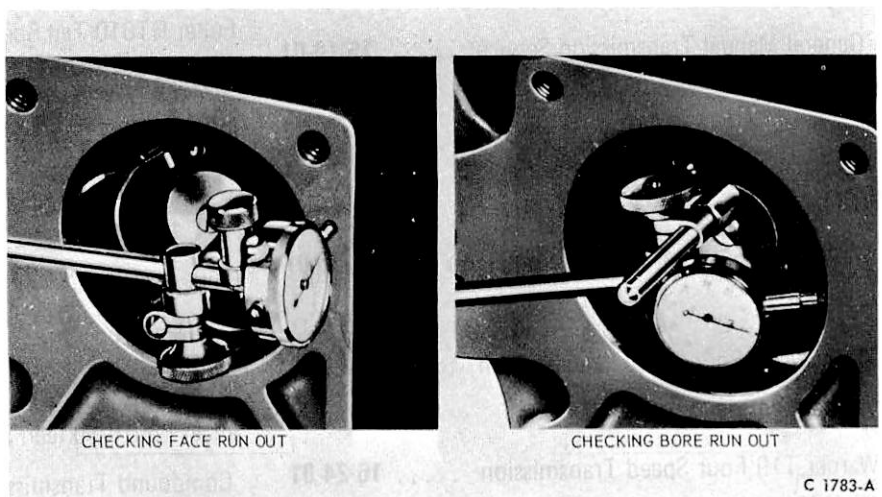

FIG. 1 Flywheel Housing Alignment Check

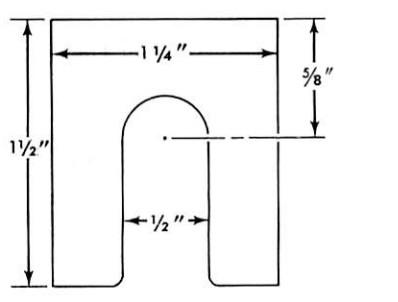

FIG. 2 Fabricated Flywheel Housing shim

9. Remove the dial indicator from the crankshaft and housing.
10. Install the spark plugs and connect the wires.

CORRECTION

Since any change in face alignment will change bore alignment, it may be possible to correct bore alignment by changing face alignment. Face alignment can be changed by shimming between the flywheel housing and engine. Fig. 2 shows the type of shim which can be fabricated.

The shim required is one half the maximum (minus) indicator reading, and should be located at the point of maximum minus indicator reading.

If both the bore and face alignment are out of limits, shim between the flywheel housing and engine to bring face alignment within limits. Check the bore alignment.

If bore alignment is out of limits and face alignment is within limits, shim the flywheel housing to the limit of face misalignment and check the bore alignment. If it is not within limits, replace the housing.

CLEANING AND INSPECTION

CLUTCH

RELEASE BEARING

Wipe all oil and dirt off the release bearing. The bearing is prelubricated and should not be cleaned with solvent. On all F-100-350, Parcel Delivery, E-100-300 and V-100 Series trucks, the clutch release bearing and hub should be serviced as a single unit. Do not disassemble for inspection or replacement.

Inspect the release bearing assembly for burrs which may cause the assembly to drag or bind on the transmission bearing retainer. Any such burrs should be cleaned up with fine crocus cloth. If burrs are found, inspect the transmission input shaft bearing retainer for evidence of scoring. Any scoring should be polished out with crocus cloth. Coat the bearing retainer with a thin film of lithium-base grease (C1AZ-19590-B). If the release bearing and hub assembly has been removed on F-100-350 and Parcel Delivery Series, lubricate the release lever fulcrum and release fingers with lithium grease (C1AZ-19590-B). Also fill the release bearing annular groove and lubricate the release lever retaining spring clips with lithium grease (C1AZ-19590-B).

Hold the bearing inner race and rotate the outer race while applying pressure to it. If the bearing rotation is rough or noisy, replace the bearing.

Most release bearing failures are caused by improper clutch pedal adjustments. If the clutch linkage does not have enough free travel, the release bearing will constantly touch the release fingers and will spin whenever the engine is running.

Release bearing failure can be caused by the release lever contact points being out of plane. Check the wear on the release bearing assembly where the release lever contacts it.

If one side of the assembly shows more wear than the other, the release lever is bent out of plane, or is not centering on the bracket on the flywheel housing.

Misalignment between the engine and transmission can cause release bearing failure. Other symptoms of misalignment are: transmission jumping out of gear, drive shaft vibration, excessive wear in the pilot bushing, excessive clutch disc spin time resulting in gear clash, and excessive transmission gear wear.

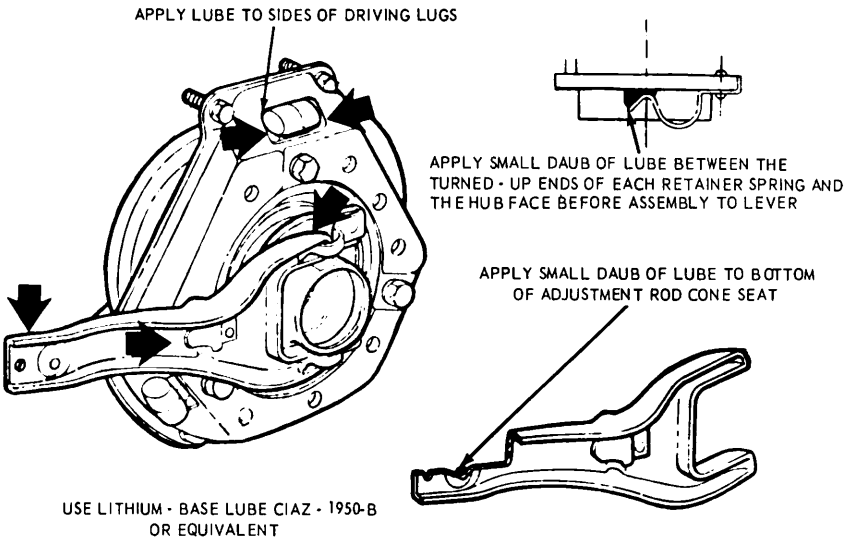

FIG. 3 Clutch Lubrication Points

PRESSURE PLATE AND COVER

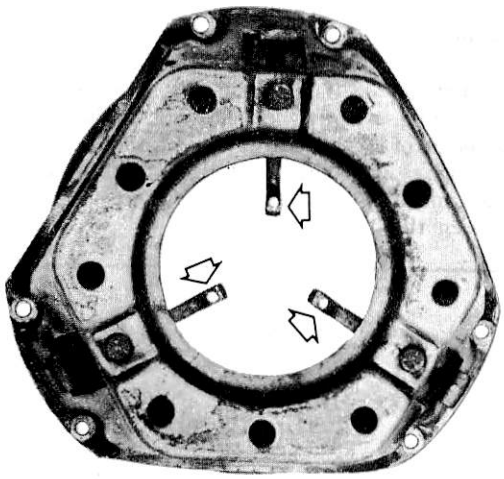
The pressure plate should be lubricated with a lithium-base grease (C1AZ-19590-B) between the driving lugs and the edges of the pressure plate openings as shown in Fig. 3. Depress the pressure fingers fully, apply the lubricant, and then move the fingers up and down until the lubricant is worked in. **Do not apply excessive lubricant.**

Inspect the surface of the pressure plate for burn marks, scores, flatness or ridges (Fig. 4). If the pressure plate is badly heat-checked or deeply scored, replace the pressure plate and cover assembly. Clean the pressure plate and the flywheel surfaces with suitable commercial solvent to be sure the surfaces are free from any oil film. **Do not use cleaners with a petroleum base, and do not immerse the pressure plate in the solvent.**

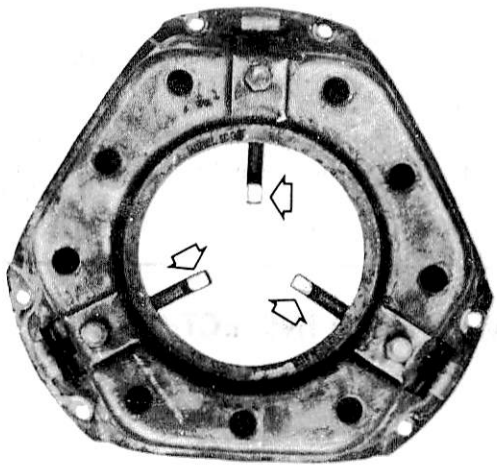
If a substantial difference in finger wear exists, the heavily worn finger is binding. Replace the pressure plate.

CLUTCH DISC

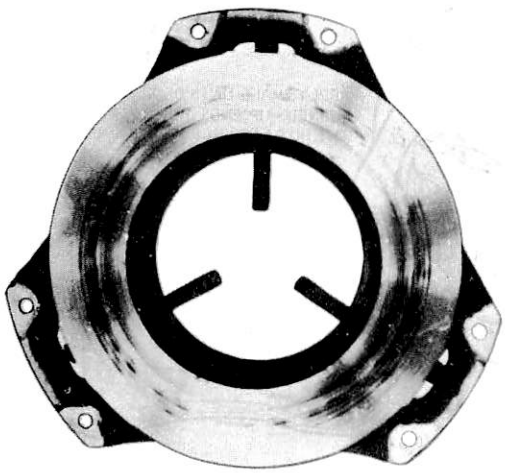
Inspect the clutch disc facings for oil or grease. **Eliminate the source of any oil or grease before replacing the disc.** An excessive amount of grease on the bearing hub will find its way to the disc facings. Too much lubricant in the



NORMAL FINGER WEAR



EXCESSIVE FINGER WEAR



SLIGHT CHATTER MARKS

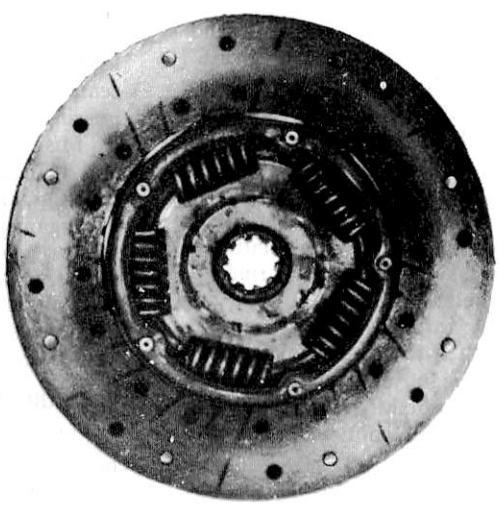
EXCESSIVE WARPAGE



WEAR PATTERN FROM
WARPED PRESSURE PLATE

C 2579-A

FIG. 4 Clutch Inspection

transmission or a plugged transmission vent will force the transmission lubricant out the input shaft and onto the disc facings. Leaking rear engine seals or loose or unsealed flywheel attaching bolts will also allow engine oil to flow onto the disc facings.

Inspect the clutch disc for worn or loose facings (Fig. 4). Check the disc for distortion and for loose rivets at the hub. Check for broken springs. **Springs loose enough to rattle will not cause noise when the vehicle is operating.**

Replace the disc if any of these conditions are present. Be especially careful when installing a new disc to avoid dropping it or contaminating it with oil or grease.

PILOT BEARING (SOLID TYPE)

Check the fit of the clutch pilot bearing in the bore of the crankshaft. The bearing is pressed into the crankshaft and should not be loose. A pilot bearing that is glazed, worn or dry, due to insufficient lubricant, often results in a temporary objectionable start-up squeal or chirping noise as the clutch is engaged or disengaged.

If inspection of the pilot bearing I.D. bore or transmission input shaft pilot shows a varnished, glazed or discolored coating, replace the bushing. Inspect the inner surface of the bearing for excessive wear or a bell-mouthed condition. Replace the bearing if it is worn or damaged. A new clutch pilot bearing normally does not require lubricant. However, due to long storage periods, it may lose some of the lubricant pressed into the bearing in manufacture. It is therefore recommended that the new bearing be soaked in SAE 30 non-detergent type motor oil for a minimum of one-half hour before installation. Wipe off all excessive oil before installing. Do not lubricate with grease of any type.

PILOT BEARING (BALL TYPE)

Check the fit and rotation of the clutch pilot bearing in the bore of the crankshaft. Replace the bearing if worn or damaged.

Inspect the pilot bearing for roughness, evidence of overheating or loss of lubricant. Replace if any of these conditions are found.

Coat the pilot bearing bore in the crankshaft with a small quantity of lithium base grease. **Avoid using too much lubricant because it may be thrown onto the clutch disc when the clutch revolves. Install the bearing with the shielded side of the bearing toward the clutch.**

ADJUSTMENTS

MULTIPLE DISC TYPE CLUTCH

INTERNAL ADJUSTMENT

The linkage on a 14 or 15 1/2 inch multiple disc clutch (Figs. 7 and 8) should not be adjusted to compensate for clutch facing wear. Linkage should only be reset to provide proper free-pedal after the internal clutch adjustment has been made. Proper linkage settings are given in Parts 16-03 and 16-04.

1. **To make an internal clutch adjustment, remove the inspection cover from the bottom of the clutch housing.**
2. Disconnect the retracting spring. Holding the release lever against the release bearing, measure the distance between the release bearing and the clutch spring hub on models with a synchronized transmission. On models with non-synchronized transmissions, measure the distance between the release bearing and the clutch brake. On vehicles equipped with a 14 inch or 15 1/2 inch two plate clutch, the dimension between the release bearing and the clutch spring hub should be 9/16-5/8 inch. the dimension between the release bearing and the clutch brake should be 1/2 inch (Fig. 1). On vehicles equipped with a 14 inch single plate clutch, the dimension between the release bearing and the clutch spring hub should be 11/32-13/32 inch.

   On all Spicer type clutches, also adjust the adjusting ring to provide a 1/8 inch clearance between the release yoke fingers and the release bearing (Fig. 2).
3. Adjust the clutch assembly by rotating the engine flywheel until the adjusting ring lock and bolt are exposed. Remove the bolt and lock (Fig. 3).
4. Hold or block the clutch pedal in the released position.
5. Use a pry bar to turn the adjusting ring (Fig. 3) counterclockwise (looking from rear of vehicle) to move the release bearing toward the flywheel; or clockwise to move the release bearing away from the flywheel. Rotation or movement of one lug position will move the release bearing approximately 1/32 inch.
6. Remove the clutch pedal block to engage the clutch.
7. Recheck the clearance as outlined in step 2. Readjust if necessary. As a final check for adequate and proper clutch adjustment, measure the distance between the centerline of the pedal pad to the firewall in the engaged position. If the distance checks 3 1/4-3 1/2 inch, the internal adjustment on the clutch is proper. Otherwise, repeat steps 2, 3, 4 and 5 above so that the specified above tolerance is obtained.
8. After the clutch has been properly adjusted, install the lock and bolt.
9. Recheck the slave cylinder push rod-to-release lever clearance if so equipped.
10. Connect the retracting spring and install the inspection cover on the clutch housing.

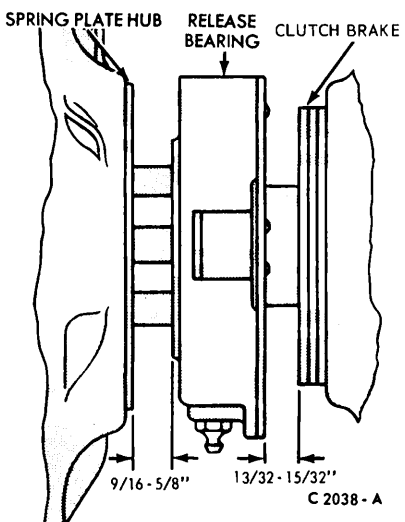

FIG. 1 Adjustment Dimensions—14 Inch Double-Disc Clutch

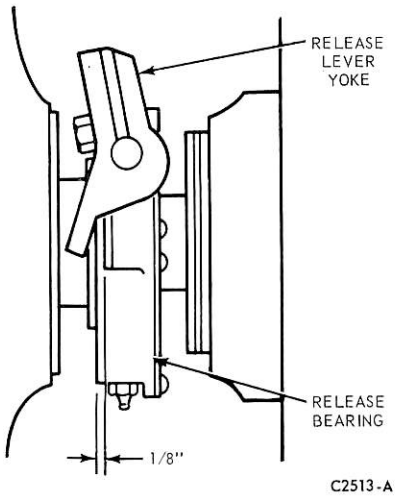

FIG. 2 Adjustment—Spicer-Type Clutch

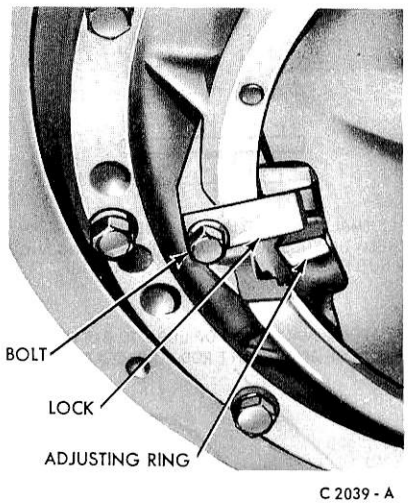

FIG. 3 Internal Adjustment — Spicer-Type Clutch

REMOVAL AND INSTALLATION

SINGLE DISC TYPE CLUTCH

STANDARD DISC (FIGS. 6 AND 7)

Removal

1. Disconnect the release lever retracting spring and push rod assembly at the lever.
2. Remove the slave cylinder attaching bolts on vehicles so equipped.
3. Refer to the appropriate transmission Part for instructions and remove the transmission from the vehicle.
4. If the clutch housing is not provided with a dust cover, remove the starting motor.

Remove the flywheel housing attaching bolts and remove the housing.

5. If the flywheel housing is provided with a dust cover, remove it from the housing. Remove the release lever and bearing from the clutch housing.
6. Mark the pressure plate and cover assembly and the flywheel, so that the parts may be installed in the same relative position.
7. Loosen the pressure plate and cover attaching bolts evenly until the pressure plate springs are expanded, and remove the bolts.
8. Remove the pressure plate and cover assembly and the clutch disc from the flywheel or through the opening in the bottom of the clutch housing.

Remove the pilot bearing only for replacement.

Installation

1. Position the disc on the flywheel so that the pilot tool can enter the clutch pilot bearing and align the clutch disc, Tool T64T-7550-A.
2. When installing the original pressure plate and cover assembly, align the assembly and flywheel according to the marks made during the removal operations. Position the pressure plate and cover assembly on the flywheel, align the pressure plate and disc, and install the retaining bolts that fasten the assembly to the flywheel. Torque the bolts to specification, and remove the clutch disc pilot tool.
3. With the clutch fully released, apply a light film of lithium-base grease (C1AZ-19590-B) on the sides of the driving lugs as shown in Fig. 4.
4. Position the clutch release bearing and the bearing hub on the release lever. Install the release lever on the trunnion in the flywheel housing. Apply a light film of lithium-base grease (C1AZ-19590-B) to the release lever fingers and to the lever trunnion or fulcrum. Fill the annular groove of the release bearing hub with grease.
5. If the flywheel housing has been removed, position it against the engine rear cover plate and install the attaching bolts. Torque the bolts to specification.
6. Check the flywheel housing alignment and adjust the housing as detailed in part 16-01.
7. Install the starter motor. Install the transmission assembly on the clutch housing. Torque the bolts to specification.
8. Apply a light film f lithium base grease the clutch housing. Torque the bolts to specification.
8. Install the slave cylinder on trucks so equipped and torque the bolts to specification.
9. Adjust the release lever push rod assembly. Connect the release lever retracting spring.
10. Install the clutch housing dust cover if so equipped.

14-INCH SINGLE DISC

Removal

1. Disconnect the clutch pedal assist spring. If necessary, remove the left-hand muffler inlet pipe.
2. Disconnect the release lever retracting spring. Remove the bolts that attach the slave cylinder to the clutch housing and remove the slave cylinder.
3. Refer to the appropriate transmission Part for instructions and remove the transmission. **Pull the transmission straight out until it is clear of the clutch assembly. An unsupported, partially removed or installed transmission can spring or distort the clutch disc.**
4. Insert two 3/4 inch wood blocks between the release bearing housing and the rear surface of the pressure plate assembly.
5. Remove the clutch to flywheel bolts and remove the flywheel ring and

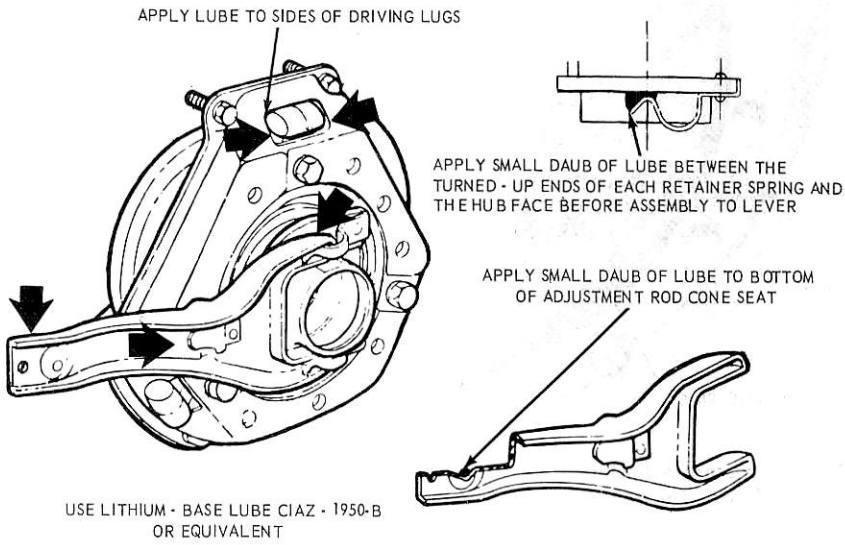

FIG. 4 Clutch Lubrication Points

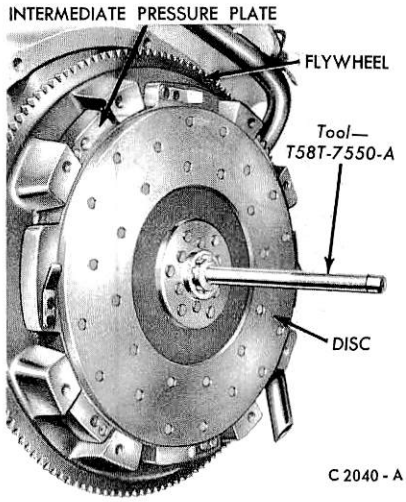

FIG. 5 Installing Discs—13-Inch Multiple Disc Clutch

pressure plate assembly. Remove the clutch disc.

Installation

1. Place the clutch disc and pressure plate assembly in position on the flywheel and start the bos. Be sure the long hub of the clutch disc is facing the rear (toward the transmission). Then, insert the clutch disc aligning Tool T61T-7550-A through the disc and into the pilot bushing. Tighten the pressure plate bolts evenly and torque them to specifications.
2. Remove the two wood blocks from the release bearing and pressure plate. Remove the aligning tool.
3. Install the transmission and drive shaft.
4. Install the slave cylinder to the clutch housing. Connect the release lever retracting spring and the left hand muffler inlet pipe if it was removed.
5. Connect the clutch pedal assist spring. Check the internal clutch adjustment, the linkage adjustment, and make necessary corrections.

MULTIPLE DISC TYPE CLUTCH

13-INCH DOUBLE DISC (FIG. 8)

Removal

1. Disconnect the clutch pedal retracting spring. If necessary, remove the muffler left inlet pipe.
2. Remove the bolts that attach the slave cylinder to the clutch housing.
3. Disconnect the slave cylinder push rod at the release lever, and disconnect the release lever retracting spring.
4. Refer to the pertinent transmission Part for instructions and remove the transmission assembly from the clutch housing. Remove the dust cover from the clutch housing.
5. Remove the clutch release bearing and hub from the release lever.
6. Mark the pressure plate and cover assembly and the flywheel, so that the parts may be installed in the same relative position.
7. Loosen the pressure plate and cover attaching bolts evenly until the pressure plate springs are expanded, and remove the bolts.
8. Remove the pressure plate and cover, the discs, and the intermediate pressure plate through the opening in the bottom of the clutch housing. **Remove the pilot bearing only for replacement,** using Tool T58L-101-A.

Installation

1. When installing a new pilot bearing use Tool 7600-G. Position the discs and second pressure plate on the flywheel so that the pilot Tool T58T-7550-A (Fig. 5) can enter the clutch pilot bushing. **When installing the original pressure plate and cover assembly, align the assembly and flywheel according to the marks made during the removal operations. The long end of the clutch disc hub must face the rear (transmission). The front (flywheel) side of the front pressure plate is stamped FLYWHEEL SIDE on one of the lugs (Fig. 6). Position the pressure plates and cover assembly on the flywheel. Align the pressure plate and discs and install the retaining bolts that fasten the assembly to the flywheel. Torque the bolts to specification, and remove the clutch disc pilot tool.**

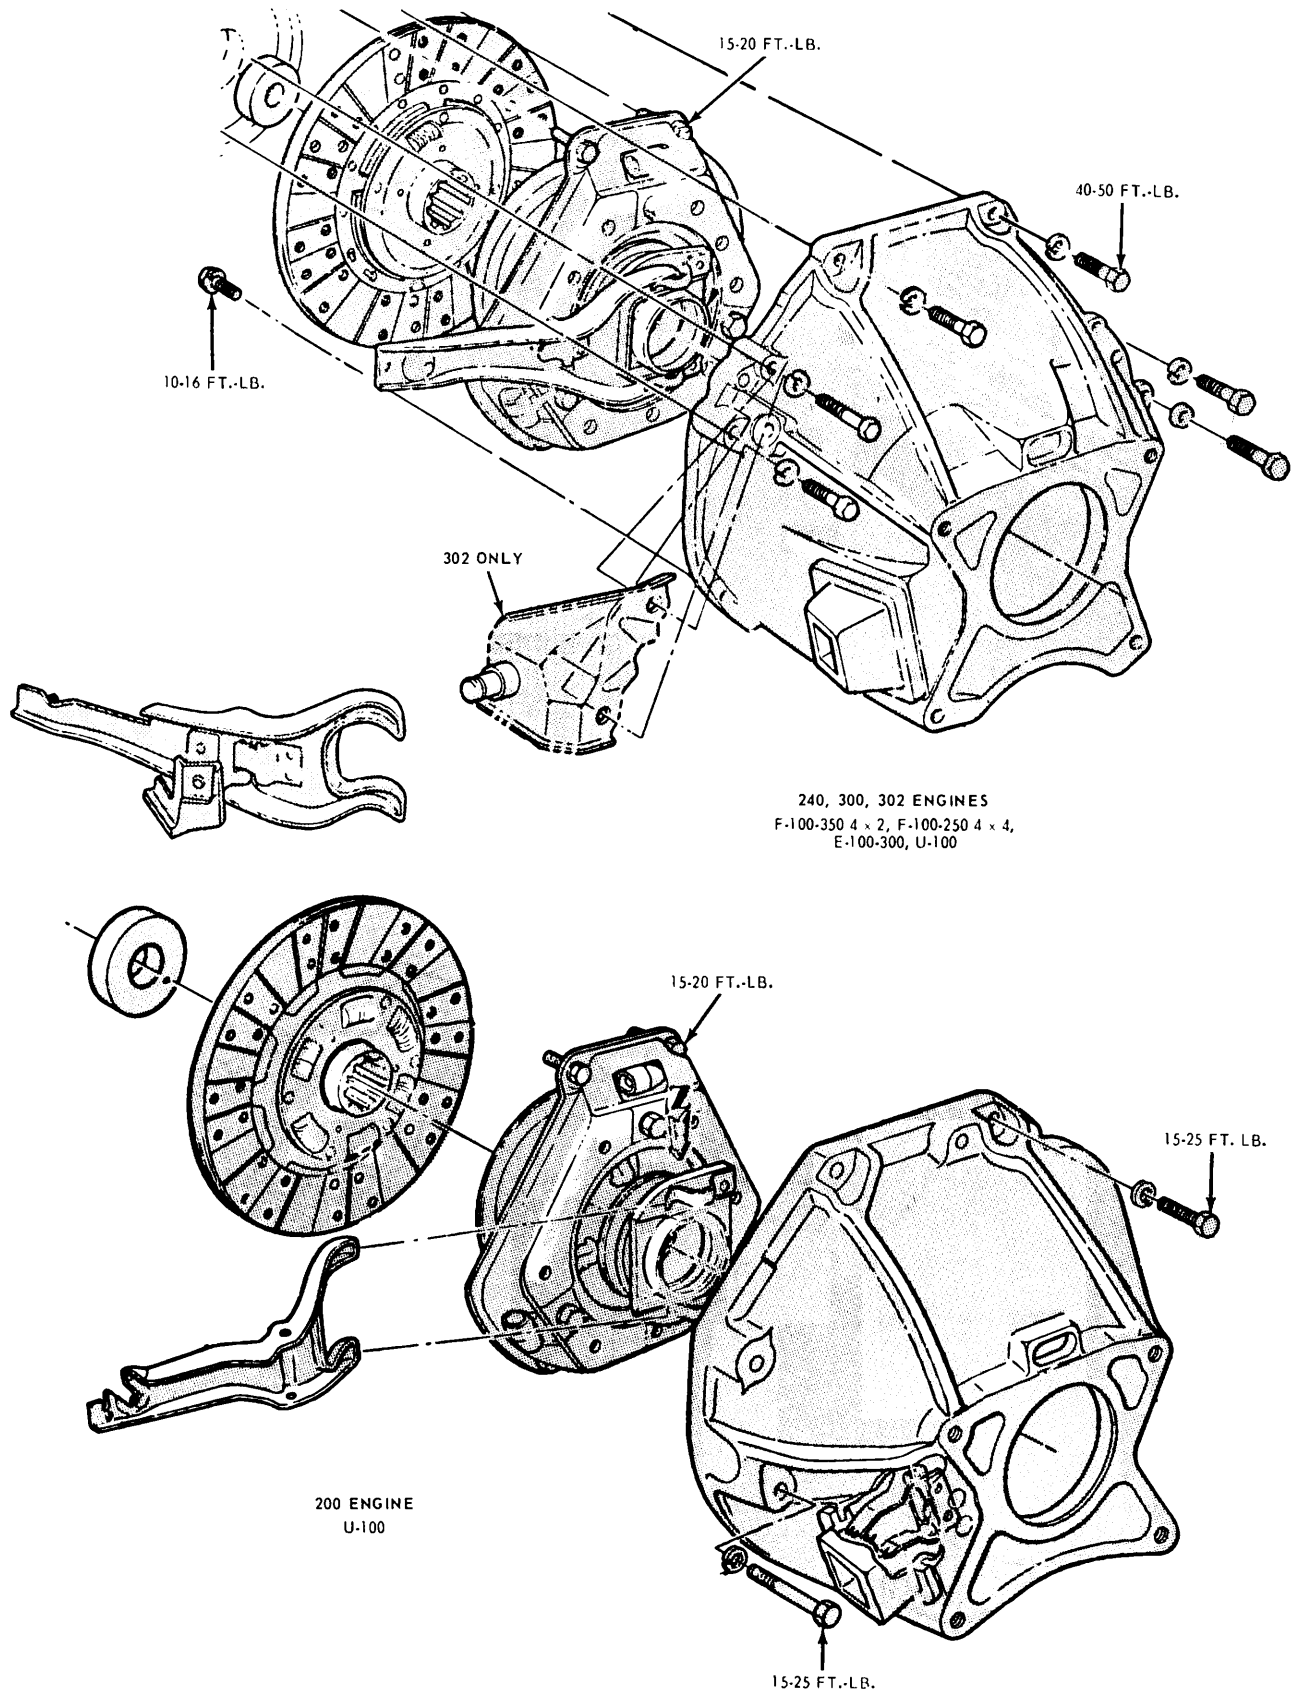

FIG. 6 Clutch Installation One-Piece Flywheel Housing

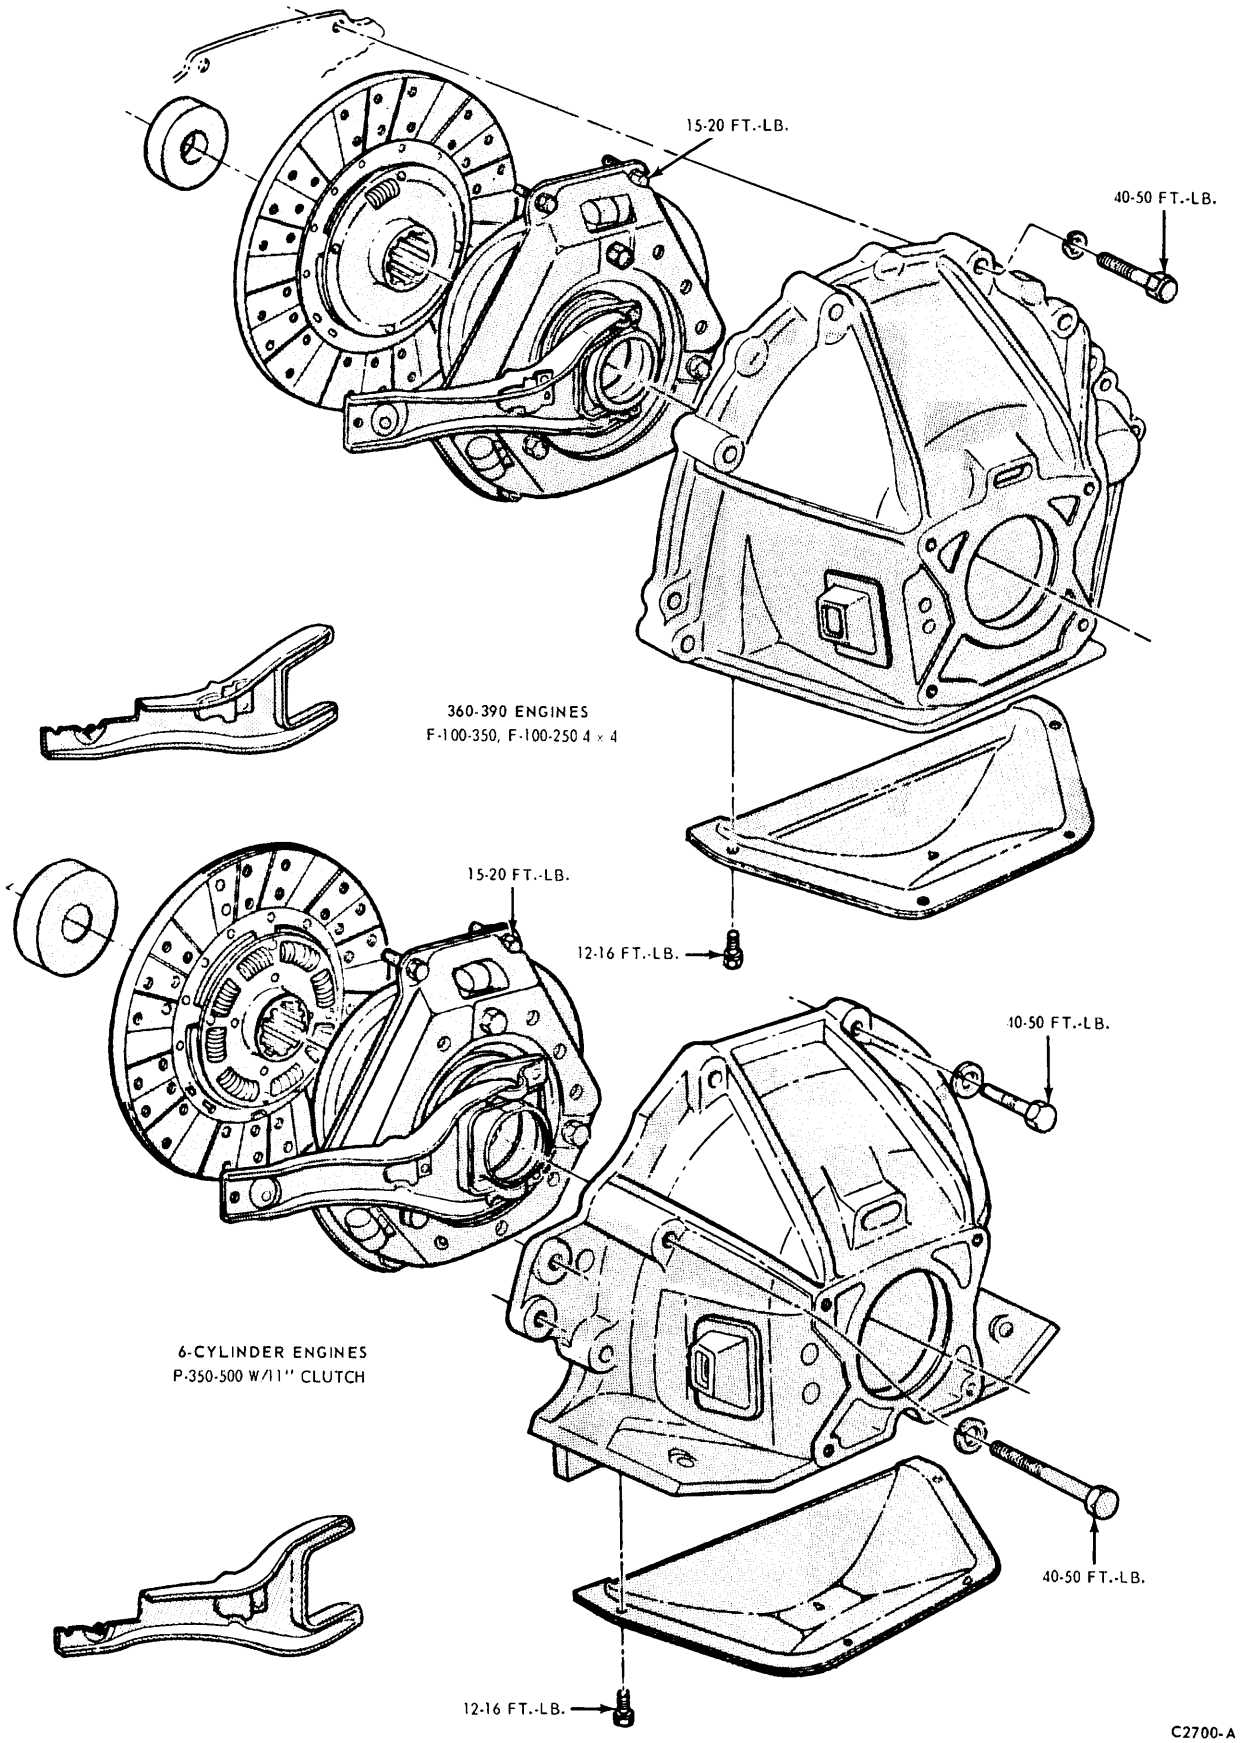

FIG. 7 Clutch Installation 2-Piece Flywheel Housing

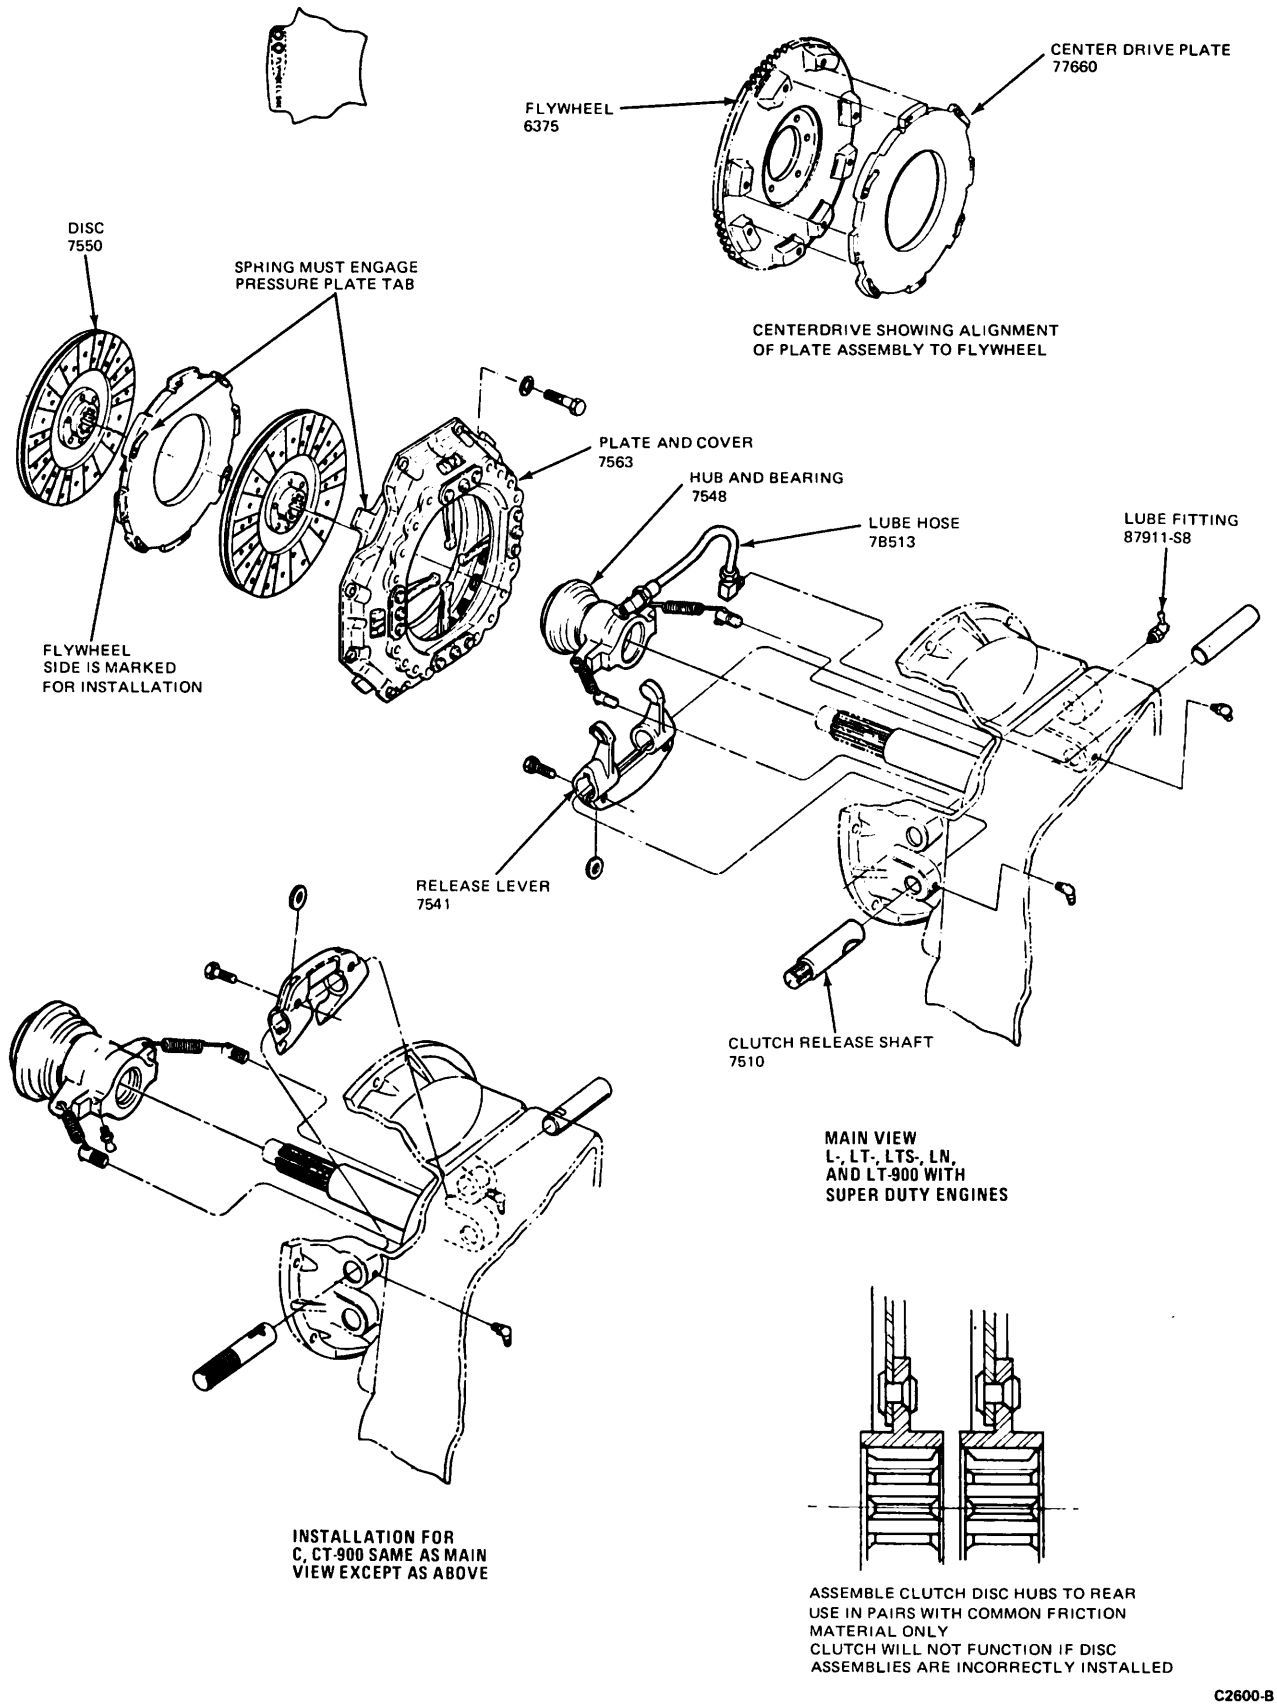

FIG. 8 13-Inch Double-Disc Clutch Installation

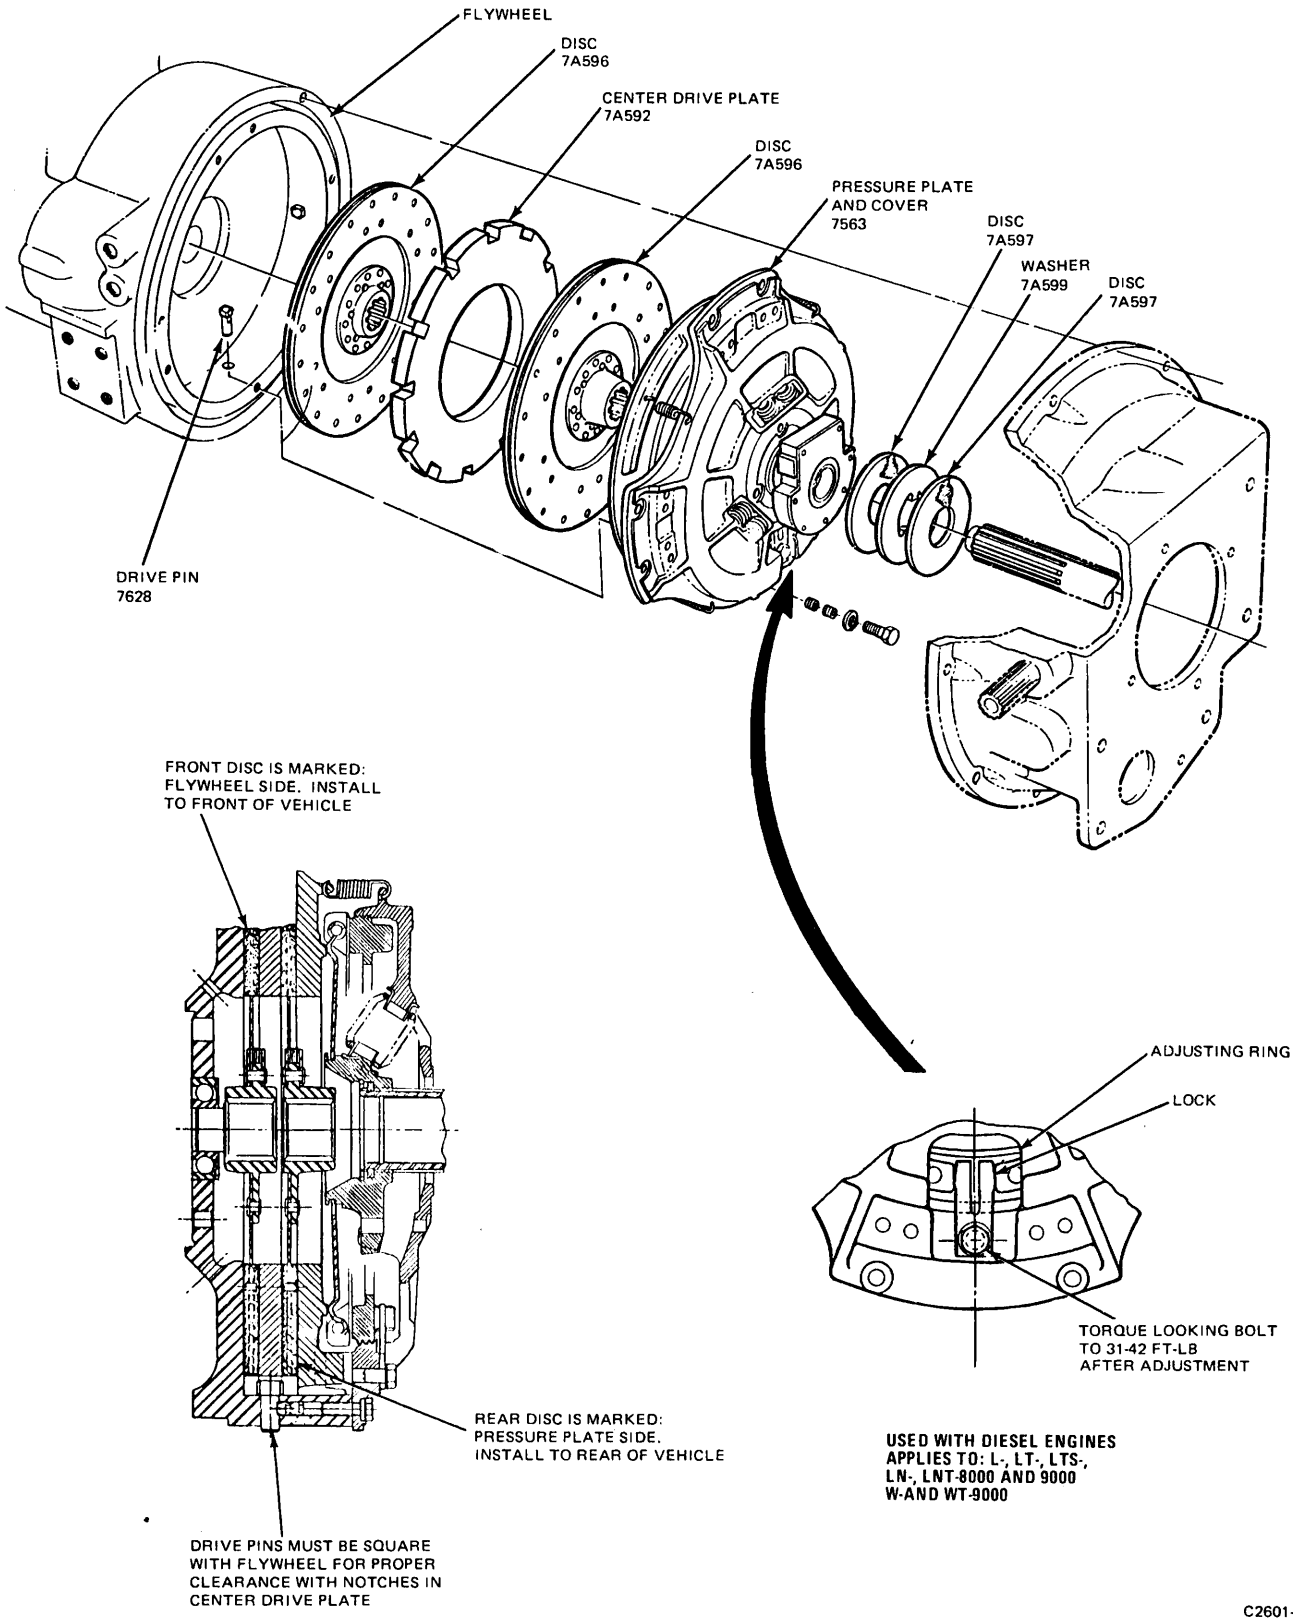

FIG. 9 14-Inch Double-Disc Clutch Installation

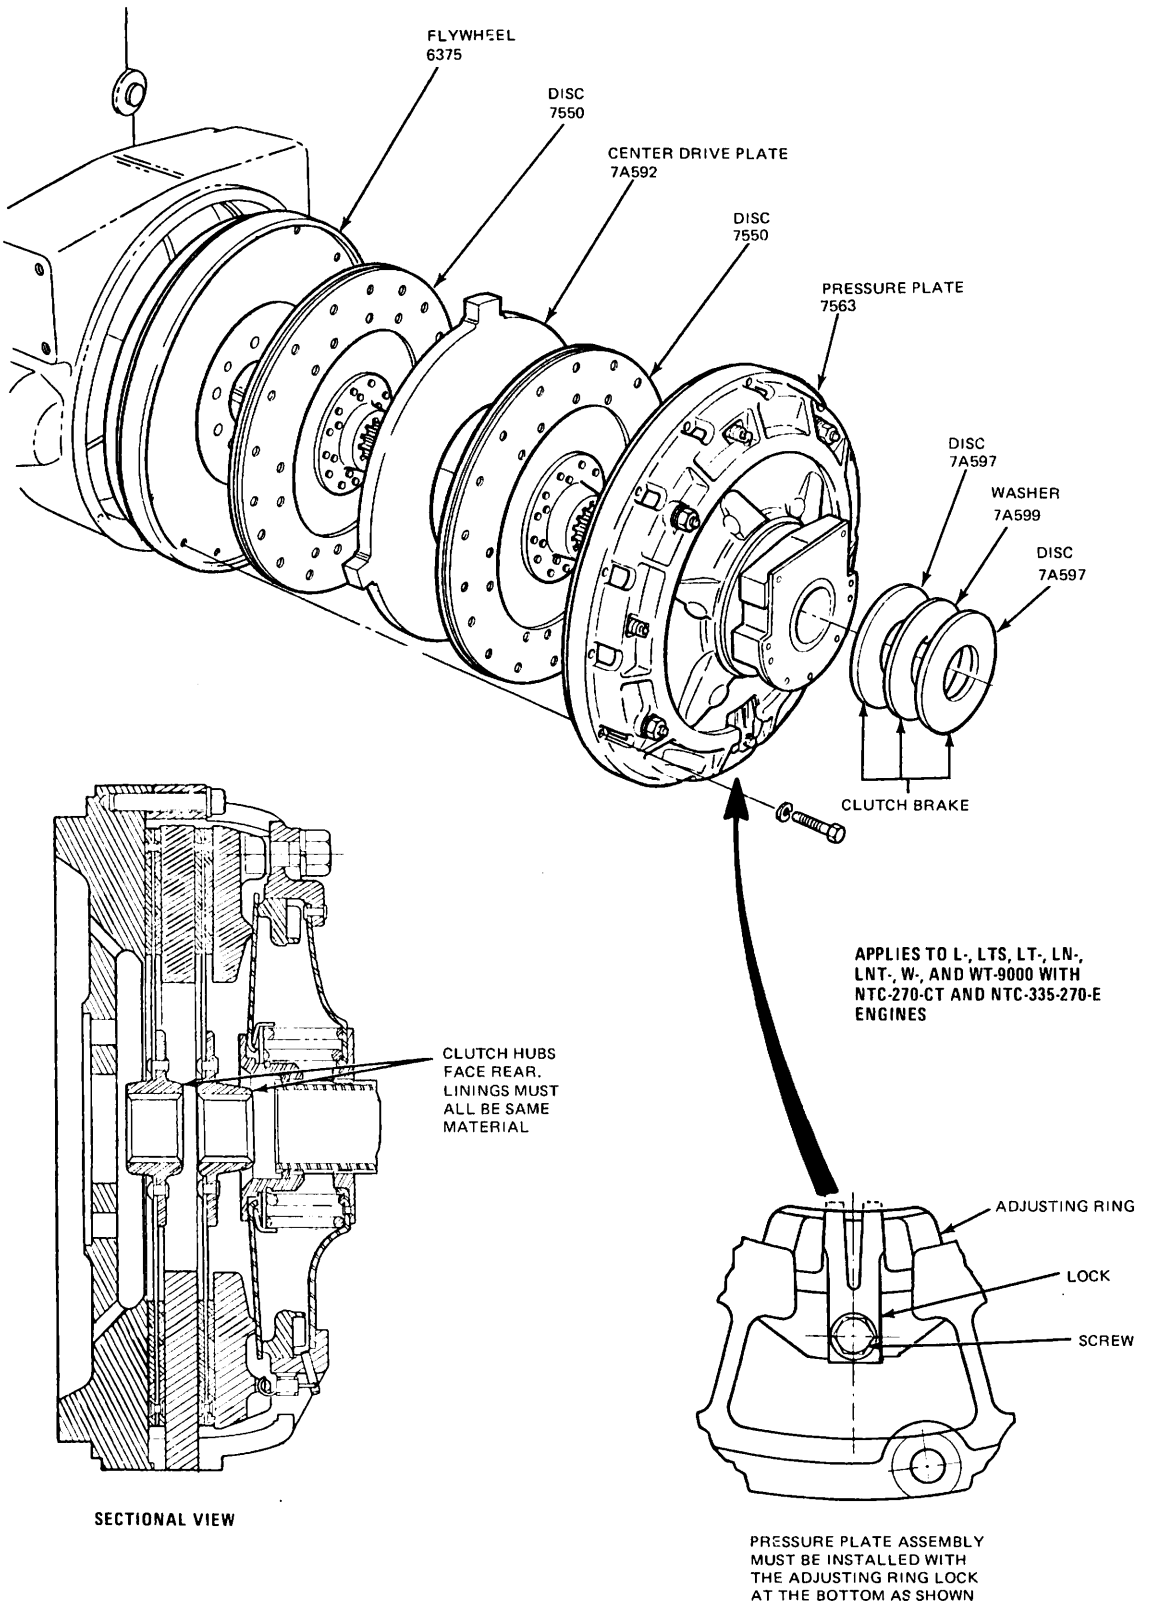

FIG. 10 15 1/2-Inch Double-Disc Clutch Installation

2. Position the clutch release bearing and the bearing hub on he release lever.
3. Install the transmission assembly on the clutch housing and torque the bolts and nuts to specifications.
4. Install the slave cylinder, and torque the bolts to specification.
5. Adjust the slave cylinder push rod. Connect the release lever retracting spring, and (if it was removed) install the muffler left inlet pipe.
6. Lubricate the release bearing through the grease fitting with 1/2 ounce of the specified lubricant.
7. Install the clutch housing dust cover.

14-INCH AND 15 1/2-INCH DOUBLE DISC (FIGS. 9 AND 10)

Removal

1. Disconnect the clutch pedal assist spring. If necessary, remove the left-hand muffler inlet pipe.
2. Disconnect the release lever retracting spring. Remove the bolts that attach the slave cylinder (if so equipped) to the clutch housing and remove the slave cylinder.
3. Refer to the pertinent transmission Part for instructions and remove the transmission. **Pull the transmission straight out until it is clear of the clutch assembly. An unsupported, partially removed or installed transmission can spring or distort the clutch disc.**
4. Insert two 3/4 inch wood blocks between the release bearing housing and the rear surface of the pressure plate assembly.
5. Remove the clutch to flywheel bolts and remove the flywheel ring and pressure plate assembly.
6. Remove the rear disc, the intermediate plate and the front disc from the engine (Figs. 7 and 8). If necessary, remove the clutch drive pin retaining set screws and remove the four intermediate pressure plate drive pins.

Installation

1. Install the intermediate pressure plate drive pins in the flywheel if they were previously removed (Fig. 8). Make sure they are a press fit. Oversize pins are available for service. Install the intermediate pressure plate and check the clearance between the pin heads and the slots in the pressure plate (Fig. 11). A clearance of 0.006 to 0.010 inch must exist, measured on the same side of all pins. Replace the pins or plate if necessary. Remove the intermediate plate, and using an adjustable square to maintain pin head alignment, install the pin set screws.
2. Place the front driven disc (shorter hub than rear disc) in the flywheel, with the hub facing the rear. Set the intermediate pressure plate in the flywheel, aligning the slots with the pins (Fig. 11). The side marked **FRONT** should face the engine. Position the rear driven disc in the flywheel with the long end of the splines hub toward the rear. Then, insert the clutch disc spline aligning Tool T61T-7550-A through the two discs and into the pilot bushing. Place the main (rear) pressure plate and flywheel ring assembly in position and start the bolts. Tighten the pressure plate bolts evenly and torque them to specification.

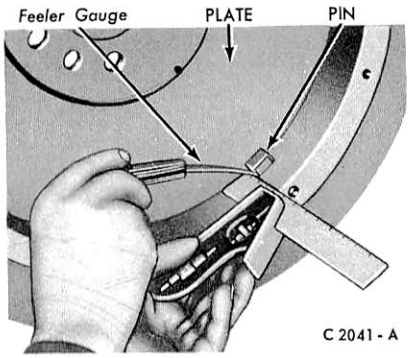

FIG. 11 Intermediate Plate Slot Clearance—Double-Disc Clutch

3. Remove the two wood blocks from the release bearing and pressure plate. Remove the spline aligning tool.
4. Install the transmission and drive shaft.
5. If the vehicle is equipped with a slave cylinder, install the slave cylinder to the clutch housing. Connect the release lever retracting spring and the left-hand muffler inlet pipe if it was removed.
6. Connect the clutch pedal assist spring. Check the internal clutch adjustment, the linkage adjustment, and make necessary corrections.

ADJUSTMENTS

CLUTCH PEDAL

ECONOLINE

1. To check and adjust the pedal total travel, measure and note the distance from the floor pan to the center of the pedal. If the pedal height is less than 7 1/2 inches or more than 7 3/4 inches, loosen the nut securing the clutch pedal eccentric bumper and rotate the bumper until the travel is within specifications (Fig. 1). Torque the nut to 10-17 ft-lbs.
2. To check and adjust the pedal free travel, slowly apply the clutch pedal until the clutch fingers contact the clutch release bearing. The distance the clutch pedal moves is the free travel dimension. The free travel should be 3/4-1 1/2 inches. If not within these limits, loosen the lock nut at the bullet on the clutch release rod (Fig. 2). Adjust the bullet until free travel is correct. Tighten the lock nut.

BRONCO

1. Measure the total travel of the pedal (Fig. 3). If the total travel is less than 6 3/4 inches or more than 7 inches, move the clutch pedal bumper and bracket up or down until the travel is within these limits. Torque the lock nut to 10-17 ft-lbs.
2. To check and adjust the pedal free travel, slowly apply the clutch pedal until the clutch fingers contact the clutch release bearing. The distance the clutch pedal moves is the free travel dimension. The free travel should be 3/4-1 1/2 inches. If not within these limits disconnect the retracting spring and loosen the nut at the bullet on the clutch release rod. Adjust the bullet until free travel is correct. Tighten the lock nut.

F-100-350 SERIES

1. Refer to Fig. 4 for adjustment points. Pedal total travel is fixed in this Series and is not adjustable.
2. Measure the clutch pedal free travel using a steel tape as shown in Fig. 6. Measure the distance from the clutch pedal pad to the steering wheel rim. Depress the pedal slowly until the free travel between the release bearing assembly and the pressure plate assembly is taken up. Note this measurement. The difference between the two measurements is the free travel.
3. If the free travel measurement is less than 3/4 inches, the clutch linkage must be adjusted.
4. Loosen the two jam nuts on the release rod assembly (Fig. 8) and back off both nuts several turns.
5. Loosen or tighten the first jam nut against the release rod extension (bullet) until a free-travel measurement indicates a 3/4 to 1 1/2 inch movement. A free travel measurement close to the 1 1/2 inch measurement is more desirable.
6. With the recommended free travel obtained, and holding the first jam nut, position and securely tighten the second jam nut against the first jam nut.
7. Re-check the pedal free travel.

Pedal Reserve

1. Start the engine and with the clutch pedal in the engaged position, move the transmission shift lever into the reverse position until a slight gear raking noise is noted. Depress the clutch pedal gradually until the raking noise is gone and the shift lever slips into the reverse position without gear clash. Noting this dimension, continue to depress the clutch pedal to its full travel and note this dimension. The difference is the pedal reserve measurement.

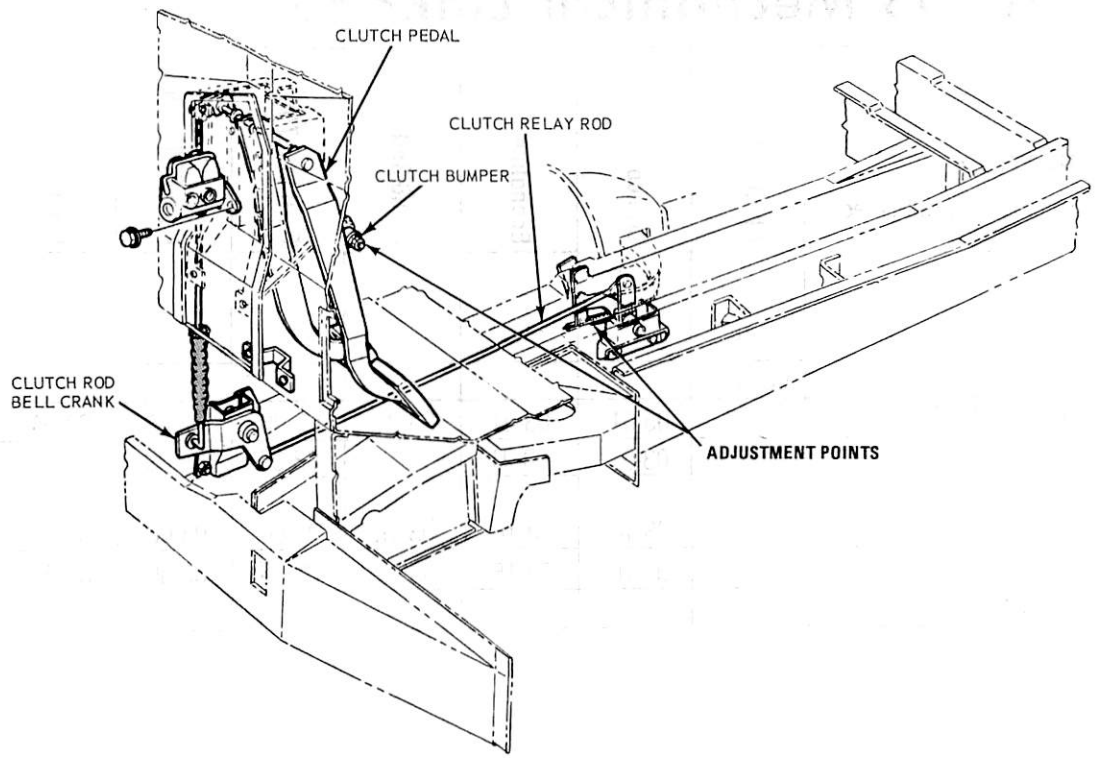

FIG. 1 Clutch Mounting and Linkage—Econoline

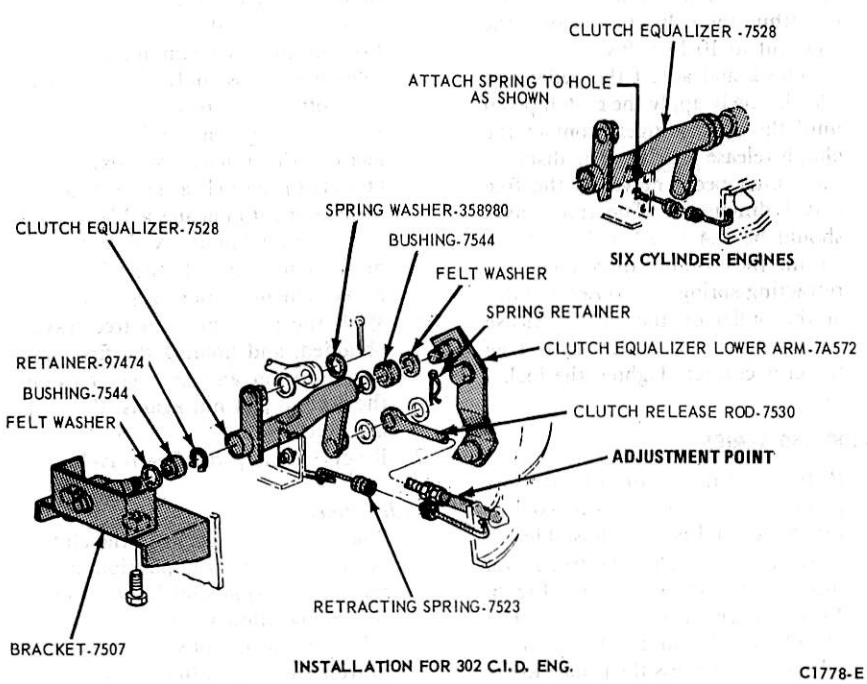

FIG. 2 Clutch Equalizer Shaft—Econoline

This reserve motion will vary with the engine used.

Spring Installation

1. Hook the short (reverse hook) end of the spring to the upper hole in the frame crossmember. Hook the long end hook into the release lever, on F-100-F-250 4 x 4 hook spring to frame bracket.

F-AND B-500 THROUGH 750 AND F-AND B-6000-7000

1. Adjust the clutch pedal stop to set total pedal travel within specification (Figs. 7 and 9). Torque the stop nut to specification.
2. On gas-engine models, adjust the clutch pedal free travel to specification by backing off the jam nut and adjusting the spherical nut on the release push rod (Fig. 9). There should be 1/4 inch clearance between the spherical nut and the release lever. Make this adjustment with the retracting spring in place.
3. Tighten the jam nut.
4. On diesel-engine models, adjust the

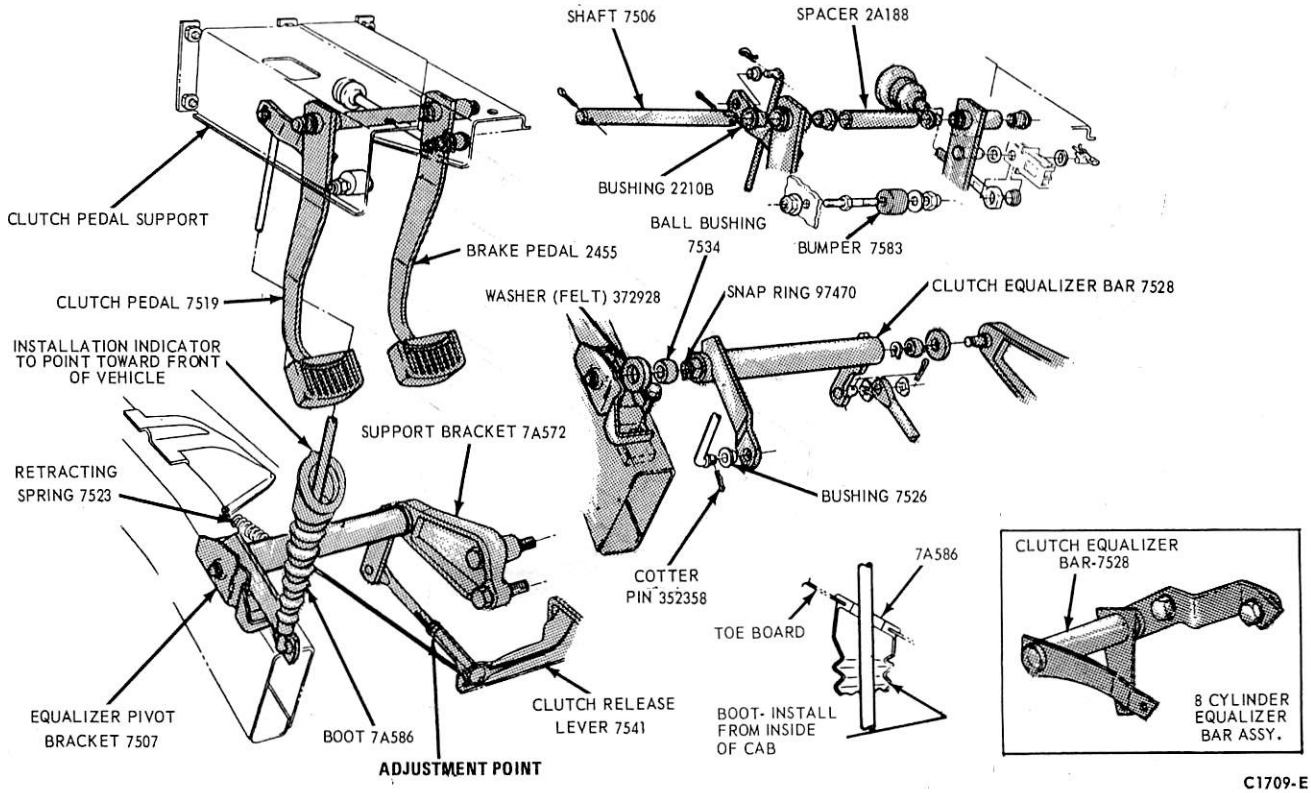

FIG. 3 Clutch Linkage—Bronco

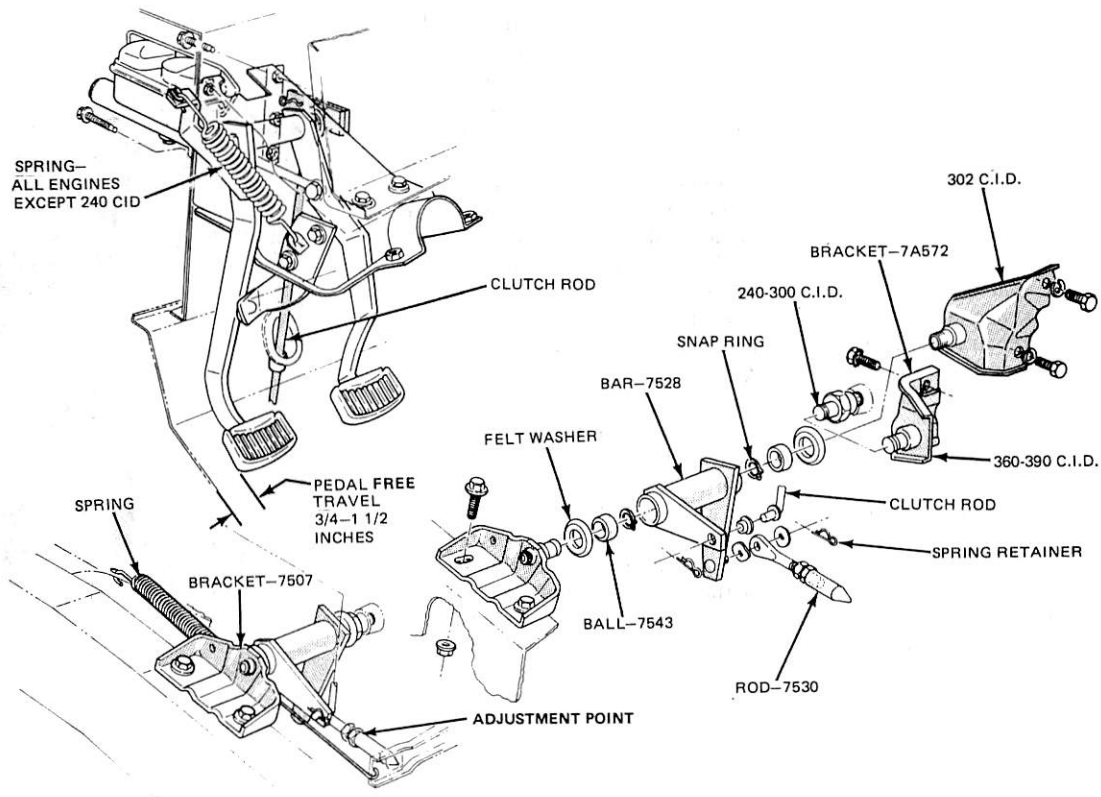

FIG. 4 F-100-350 Series Clutch

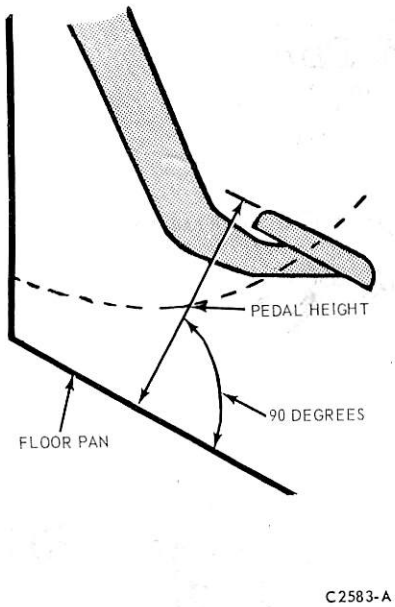

FIG. 5 Measuring Pedal Height

clearance between the sleeve and lever as shown in fig. 9. Clearance should be 1/8 inch.

5. Tighten the jam nut.

L-SERIES

A common pedal is used on all L-Series trucks (Fig. 10). Refer to Fig. 10 for instructions on adjusting pedal total travel and dimension locations for installation and free pedal measurements.

Refer to the appropriate illustration for linkage and clutch free pedal adjustments. Please note that it is not necessary to set the total clutch linkage each time the clutch is adjusted for pedal free travel. Also note that double disc spicer-type clutches are adjusted **internally** for pedal free travel. **This procedure must be used on these clutches to prevent premature clutch failure.**

W-SERIES

1. Adjust the clutch pedal stop to permit total pedal travel of 10 15/32 to 10 31/32 inches (Fig. 18). Torque the bracket attaching bolts to specifications.
2. Adjust the clutch pedal over-center assist spring by means of the spherical locking nut to provide a spring length of 7 3/16-7 5/16 inches for 500 pound clutch and 6 15/16-7 1/16 inches for 420 pound clutch. This distance should be measured inside of the spring eye ends (Fig. 19). When making the spring adjustment, hold the spring retainer from rotating and make certain the assist spring and anchor are aligned at right angles as shown in Fig. 18. When adjusting the assist spring anchor, use a deep socket wrench to avoid damaging the plastic-insert locknut.
3. Adjust the vertical tension rod turnbuckle so that the lever (Fig. 18) is perpendicular to the top of the frame. This adjustment to be made with the cab in the locked position and a 1/4 inch diameter aligning pin installed in the lever. After the adjustment, position the thin section of the turnbuckle toward the body sheet metal so as to provide maximum clearance between the sheet metal and radiator side support. Do not remove the aligning pin at this time.

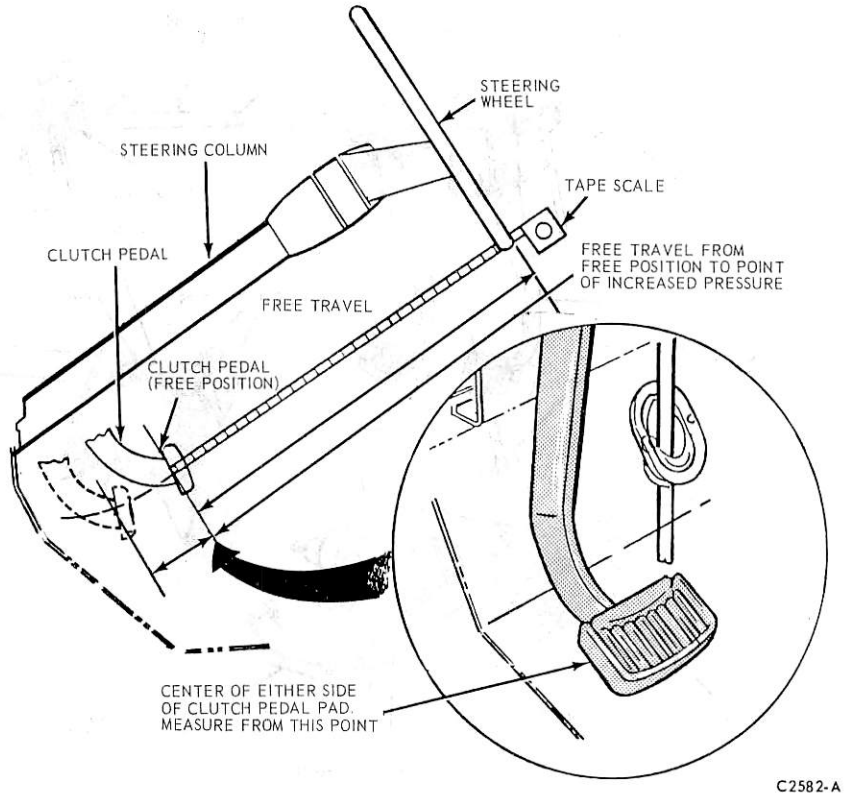

FIG. 6 Measuring Free Travel

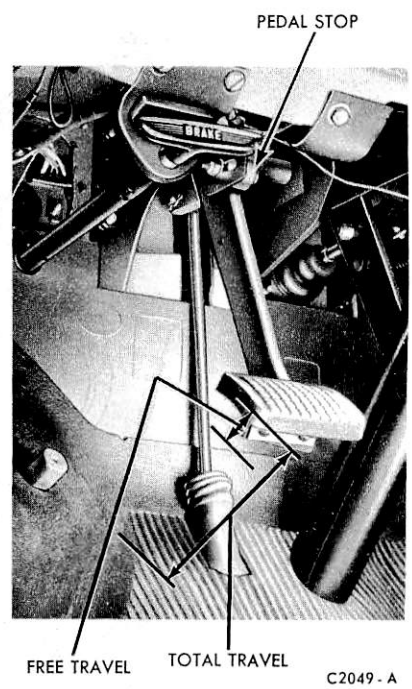

FIG. 7 Clutch Pedal Travel

4. With another 1/4 inch diameter aligning pin inserted through the frame bracket and outer equalizer lever, check the inner equalizer lever to be sure it is perpendicular to the top of the frame. If the lever is not perpendicular, adjust the rod length as required. Remove both aligning pins.
5. Position the linkage return spring clip to the dimension shown in Fig. 18.
6. Disconnect the equalizer rod at the clutch housing cross-shaft lever.
7. While holding the clutch housing cross-shaft lever in the rearward position, adjust the length of the equalizer rod so that the hole in the clevis and the hole in the cross-shaft lever are aligned. Then, back-off the clevis 7 1/2 turns and rotate the cross-shaft lever forward. Connect the equalizer rod at the cross-shaft lever and tighten the locknuts at all the clevis connections. The resulting clutch pedal free travel will be approximately 1 3/8-1 1/2 inches, corresponding to a 1/2 inch free bearing lash at the clutch bearing hub.
8. With linkage correctly set, make all further service adjustments for clutch facing wear by internally adjusting the clutch to the specified 1/2 inch clearance. This action should automatically restore the specified pedal free travel.

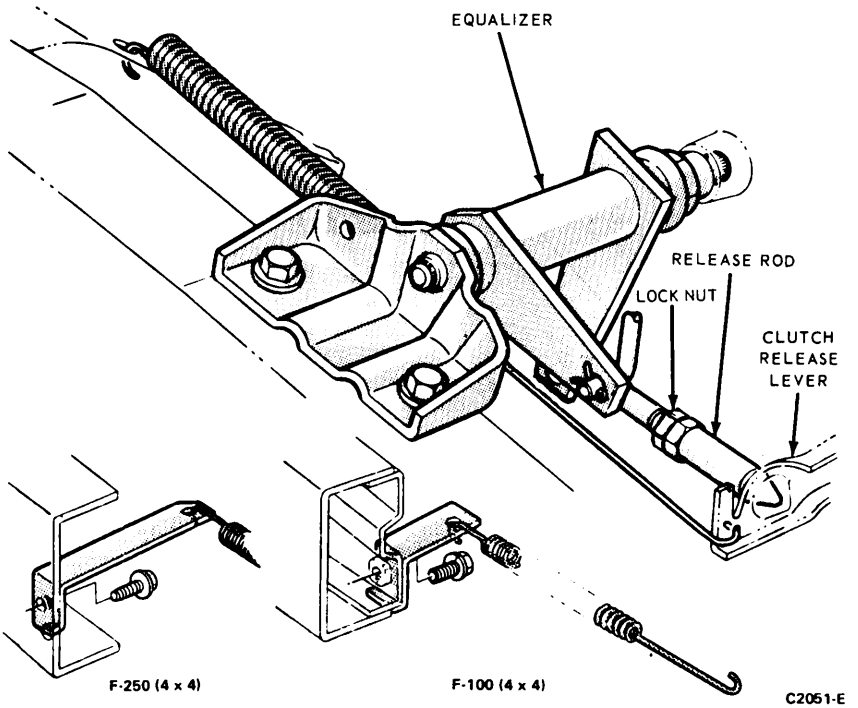

FIG. 8 Clutch Pedal Free Travel Adjustment—F-100-350 Series

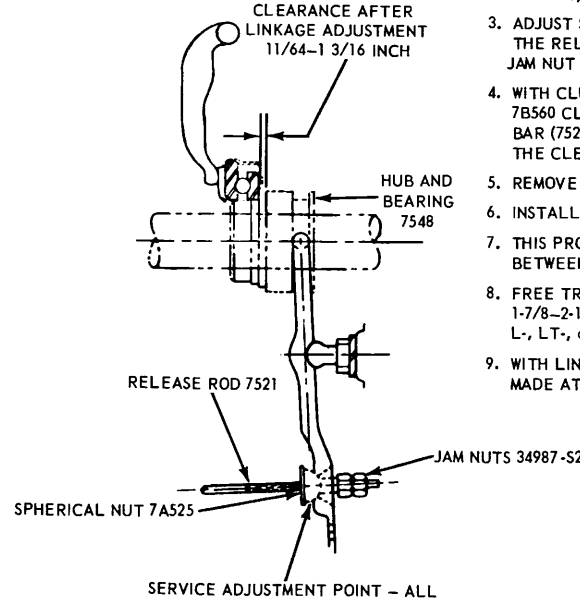
L, LT, LTS-800 WITH MODELS 280, 542, AND 5000 TRANSMISSIONS



1. ADJUST CLUTCH PEDAL TOTAL TRAVEL. DISCONNECT CLUTCH RETRACTING SPRING AND CLUTCH ROD 7B560.
2. INSTALL 0.25 GAUGE PIN AS SHOWN. ON L, LT, AND LTS-800 MODELS, ADJUST ROD 7604 TO DIMENSION SHOWN.
3. ADJUST SPHERICAL NUT 7A525 TO REMOVE ALL LASH BETWEEN THE RELEASE BEARING AND THE CLUTCH FINGERS. TIGHTEN JAM NUT 34987-S2.
4. WITH CLUTCH PEDAL HELD AGAINST ITS STOP, ADJUST CLUTCH ROD 7B560 CLEVIS UNTIL THE CLEVIS PIN FITS FREELY THROUGH THE BAR (7528) OR BELLCRANK (7B585). LENGTHEN THE ROD BY TURNING THE CLEVIS 5 FULL TURNS.
5. REMOVE THE GAUGE PIN AND INSTALL THE CLUTCH ROD 7B560.
6. INSTALL THE RETRACTING SPRING.
7. THIS PROCEDURE SHOULD GIVE A CLEARANCE OF 11/64– 3/16 INCH BETWEEN THE RELEASE BEARING AND THE CLUTCH FINGERS.
8. FREE TRAVEL AT CENTER OF CLUTCH PEDAL PAD SHOULD BE 1-7/8–2-1/8 INCH FOR LN-750 AND 2-1/4–2-1/2 INCH FOR LN-, LNT-, L-, LT-, and LTS-800 MODELS.
9. WITH LINKAGE CORRECTLY SET, ALL SERVICE ADJUSTMENTS ARE MADE AT THE CLUTCH RELEASE LEVER.

CLUTCH PEDAL
FREE TRAVEL 2-3/32 TO 2-5/16

CLUTCH LINKAGE ADJUSTMENT

1. DISCONNECT RETRACTING SPRING.
2. ADJUST CLUTCH PEDAL TOTAL TRAVEL AND RELEASE BEARING CLEARANCE.
3. DISCONNECT CLUTCH ROD 7B560 AT BAR 7528 AND INSTALL 0.25 INCH GAUGE PIN.
4. ADJUST ROD 7530 TO SECURE ZERO RELEASE BEARING LASH. BE SURE THAT BAR-TO-BELLCRANK DIMENSION IS AS SHOWN.
5. WITH THE PEDAL HELD AGAINST ITS STOP, ADJUST CLUTCH ROD 7B560 UNTIL THE CLEVIS PIN FITS FREELY IN BAR 7528.
6. REMOVE THE ALIGNMENT PIN.
7. LENGTHEN CLUTCH ROD 7B560 5 TURNS AND CONNECT TO BAR 7528. CONNECT RETRACTING SPRING.
8. CHECK RELEASE BEARING CLEARANCE, WHICH SHOULD BE AS SHOWN. IT IS NOT NECESSARY TO ADJUST CLUTCH LINKAGE EACH TIME THE PEDAL FREE TRAVEL IS ADJUSTED. MAINTAIN PEDAL FREE TRAVEL BY ADJUSTING AT THE POINT SHOWN.

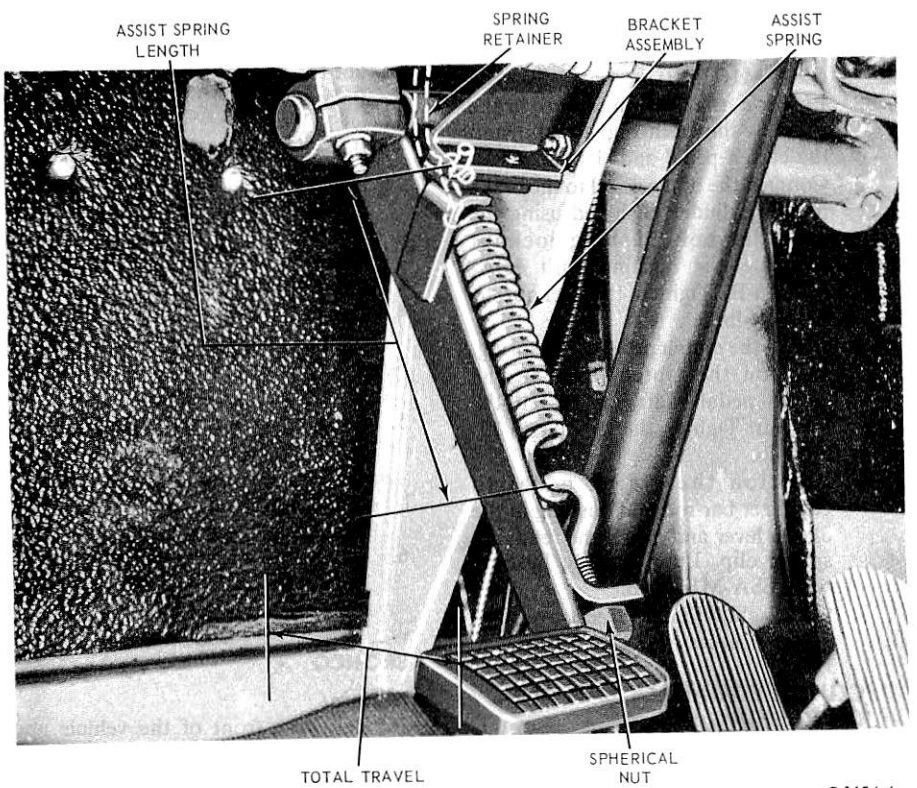

FIG. 19 Clutch Pedal and Assist Spring Adjustments—W-Series

REMOVAL AND INSTALLATION

CLUTCH PEDAL AND/OR BUSHING

ECONOLINE

Removal

1. Working under the dash, remove the retainer spring clip and disconnect the clutch pedal to equalizer bar rod (Fig. 1). Remove bushing from lever.
2. Remove the lock nut attaching the clutch lever to the clutch pedal assembly shaft and remove the lever.
3. Remove the shoulder bolt, bushing and locknut attaching the brake pedal to the master cylinder push rod.
4. Pull the clutch pedal and shaft outboard and remove the brake pedal and bushings along with the clutch pedal and shaft.

Installation

1. Lubricate the clutch pedal shaft and bushings with lithium base grease (ESA-M1C75-B).
2. Position the bushings and brake pedal as shown in Fig. 1 and install the clutch pedal and shaft.
3. Connect the brake pedal to the brake master cylinder push rod using the shoulder bolt, bushing and locknut Lubricate the bushing with ESA-M1C75-B. Tighten the locknut to 18-28 ft-lb.
4. Install the clutch pedal assist spring.
5. Position the clutch lever on the clutch pedal shaft and install the locknut. Tighten the locknut to 25-30 ft-lb.
6. Lubricate the bushing with ESA-M1C75-B and position the clutch pedal to equalizer bar rod and bushing in the clutch lever and install the retaining cotter pin.
7. Check clutch pedal free travel and adjust if necessary (Fig. 1).

BRONCO

Removal

1. Remove the spring retainer clip and disconnect the clutch pedal to equalizer bar rod from the clutch pedal (Fig. 3).
2. Remove the outboard spring retainer from the clutch pedal shaft and push the shaft inboard until the clutch pedal and bushings can be slid off the shaft.
3. Remove the pedal and bushings.

Installation

1. Lubricate the clutch pedal shaft and all bushings with lithium base grease (ESA-M1C75-B).
2. Position the shaft and bushings as shown in Fig. 3 and install the pedal.
3. Push the clutch pedal shaft outboard until it is in position. Install the spring retainer clip.
4. Connect the clutch pedal to equalizer bar rod and bushing to the clutch pedal and install the spring retainer clip. Lubricate the bushing with lithium base grease (ESA-M1C75-B).

F-100-350

Removal

1. Working under the dash, remove the retainer spring clip and disconnect the clutch pedal to equalizer bar rod (Fig. 4).
2. Remove the assist spring and insulators (if so equipped).
3. Remove the lock nut attaching the clutch lever to the clutch pedal assembly shaft and remove the lever.
4. Remove the shoulder bolt bushing and locknut attaching the brake pedal to the master cylinder push rod.
5. Pull the clutch pedal and shaft outboard and remove the brake pedal and bushings along with the clutch pedal and shaft.

Installation

1. Lubricate the clutch pedal shaft and bushngs with lithium base grease (ESA-M1C75-B).
2. Position the bushings and brake pedal as shown in Fig. 4 and install the clutch pedal and shaft.
3. Connect the brake pedal to the brake master cylinder push rod using the shoulder bolt bushing locknut lubricate the bushing with ESA-M1C75-B. Tighten the locknut to 18-28 ft-lb.
4. Install the clutch pedal assist spring.
5. Position the clutch lever on the clutch pedal shaft and install the locknut. Tighten the locknut to 25-30 ft-lb.
6. Position the clutch pedal to equalizer bar rod and bushing in the clutch lever and install the retaining spring clip. Lubricate the bushing with ESA-M1C75-B.
7. Check clutch pedal free travel and adjust if necessary (Fig. 4)

CLUTCH EQUALIZER BAR AND/OR BUSHING

ECONOLINE

Removal

1. Raise the front of the vehicle, and position safety stands.
2. Disconnect the clutch release lever retracting spring. Remove the spring retainer and washer from the equalizer bar lower pivot arm, and disconnect the clutch release rod (Fig. 2).
3. Remove the retainer and spring washer from the equalizer bar upper pivot arm, and disconnect the clutch pedal-to-equalizer bar rod.
4. Remove the locknuts and bolts that attach the equalizer bar mounting bracket to the under body side rail, then pull the bracket and equalizer bar assembly from the engine mounted pivot.
5. Remove the mounting bracket from the equalizer bar. Remove the bushings from both ends of the equalizer bar, if they did not remain on the pivots.

Installation

1. Assemble the integral mounting bracket and outer pivot and the bushing to the equalizer bar, then position the other end of the equalizer bar and bushing to the engine-mounted pivot (Fig. 2). Lubricate the bushings with ESA-M1C75-B lithium base grease.
2. Position the mounting bracket to the underbody side rail, and install the mounting bolts and locknuts. Do not torque the locknuts at this time.
3. Pack both ends of the equalizer bar with ESA-M1C75-B lube. Adjust the mounting bracket by pushing the bracket toward the center of the truck so that the equalizer bar covers both pivots and both bushings, then torque the mounting nuts to specification.
4. Connect the clutch pedal-to-equalizer bar rod to the equalizer bar upper pivot arm, and install the washer and retainer.
5. Connect the clutch release rod to the equalizer bar lower pivot arm, install the spring washers and cotter pin, and connect the clutch release lever retracting spring.
6. Adjust the clutch pedal free travel. Remove the safety stands, and lower the vehicle.

BRONCO

Removal

1. Raise the front of the vehicle and install safety stands.
2. Disconnect the clutch release lever retracting spring.
3. Remove the spring retainer and disconnect the clutch pedal to

equalizer bar rod and bushing from the equalizer upper arm (Fig. 3).
4. Remove the capscrews attaching the outer equalizer pivot bracket to the chassis frame and remove the bracket and equalizer bar.
5. Remove the spring retainer and disconnect the clutch release rod and spring washers from the equalizer bar (Fig. 3).
6. Remove the snap rings holding the equalizer bar bushings to the inner and outer pivot brackets and remove the bushings and washers.

Installation

1. Lubricate all bushings and pivot points with lithium base grease ESA-M1C75-B. Position the felt washers and ball-shaped bushings on the inner and outer pivot brackets as shown in Fig. 3 and install the snap rings.
2. Pack the cavities in the ends of the equalizer bar with lubricant ESA-M1C75-B. Position the equalizer bar over the inner pivot and install the outer pivot and bracket to the frame. Torque the attaching capscrews to specification (20-30 ft-lb).
3. Position the clutch release rod on the equalizer and install the spring washers and spring retainer.
4. Lubricate the clutch pedal to equalizer bar rod and bushing with ESA-M1C75-B. Connect to the equalizer bar and install the spring retainer.
5. Lubricate the clutch release rod with ESA-M1C75-B and connect to the clutch release lever. Connect the retracting spring.
6. Check clutch pedal free travel and adjust as necessary.
7. Remove the safety stands and lower the vehicle.

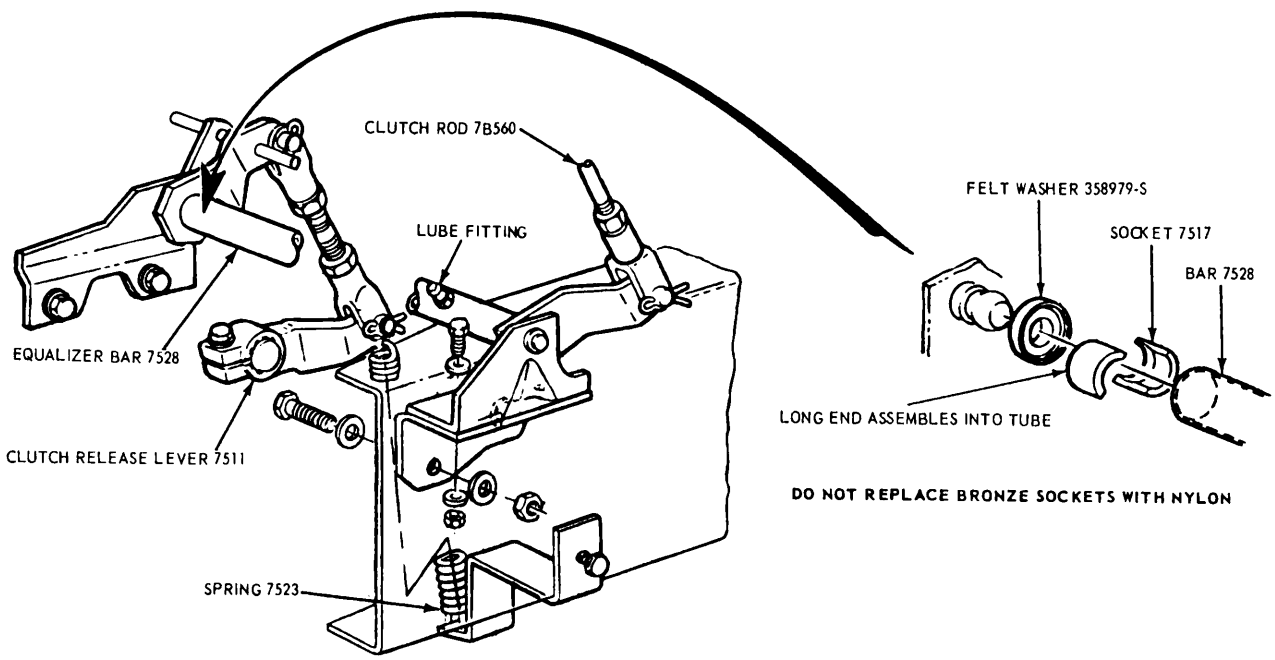
F-100-350 (4X2) (4X4)

Removal

1. Raise the front of the vehicle and install safety stands.
2. Disconnect the clutch release lever retracting spring.
3. Remove the retainer spring clip and disconnect the clutch pedal to equalizer bar rod and bushing from the equalizer outer arm (Fig. 4).
4. Remove the capscrews attaching the outer equalizer bar pivot bracket to the chassis frame and rmove the bracket and equalizer bar.
5. Remove the retainer spring clip and disconnect the clutch release rod assembly and spring washers from equalizer bar inner arm (Fig. 4).
6. Remove the snap rings holding the equalizer bar bushings to the inner and outer pivot brackets and remove the bushings and washers.

Installation

1. Lubricate all bushings and pivot points with lithium base grease. Position the felt washers and ballshaped bushings on the inner and outer pivot brackets as shown in Fig. 4 and install the snap rings.
2. Pack the cavities in the ends of the equalizer bar with lubricant ESA-M1C75-B. Position the equalizer bar over the inner pivot and install the outer pivot and bracket to the frame. Torque the attaching capscrews to specification (20-30 ft-lb). **Equalizer bar assembly should be parallel to dash panel and the ground and perpendicular to the engine crankshaft centerline.**
3. Position the clutch release rod assembly on the equalizer and install the spring washers and retainer sping clip.
4. Connect the clutch pedal to equalizer bar rod and bushing to the equalizer bar and install the cotter pin. Lubricate the bushing with lithium base grease ESA-M1C75-B.
5. Position the clutch release rod to the clutch release lever and connect the retracting spring. Lubricate release lever and release rod assembly with ESA-M1C75-B.
6. Check clutch pedal free travel and adjust as necessary (Fig. 4).
7. Remove the safety stands and lower the vehicle.



C 2604-A

FIG. 20 Clutch Equalizer Bar—L-Series

L-SERIES

Disconnect points for this equalizer bar are shown in fig. 20. Linkage adjustments for L-Series are shown in this Part.

When replacing bushings in this equalizer bar, be sure not to replace bronze bushings with nylon. Bronze bushings are used in some installations because of their heat resistance.

CLUTCH PEDAL ADJUSTMENT		CLUTCH HYDRAULIC SYSTEM BLEEDING METHOD – ALL VEHICLES	
P-Series	04-01	Pressure Tank Bleeding	04-01
C-Series	04-01	Gravity Bleeding Method	04-01

ADJUSTMENTS

CLUTCH PEDAL

Before making any adjustments, be sure that the system is free of air and that the master cylinder fluid is at the specified level.

P-SERIES

P-350-400

Adjust the clutch slave cylinder push rod per the instructions shown in Fig. 1.

P-500

Adjust the clutch master cylinder and slave cylinder push rods per the instructions shown in Fig. 2.

C-SERIES

Adjust the C-Series clutch pedal and clutch slave cylinder per the instructions shown in Fig. 3.

CLUTCH HYDRAULIC SYSTEM BLEEDING METHOD—ALL VEHICLES

An effective and simplified method has been developed for bleeding clutch hydraulic systems with a minimum waste of hydraulic clutch fluid. Instructions are given below:

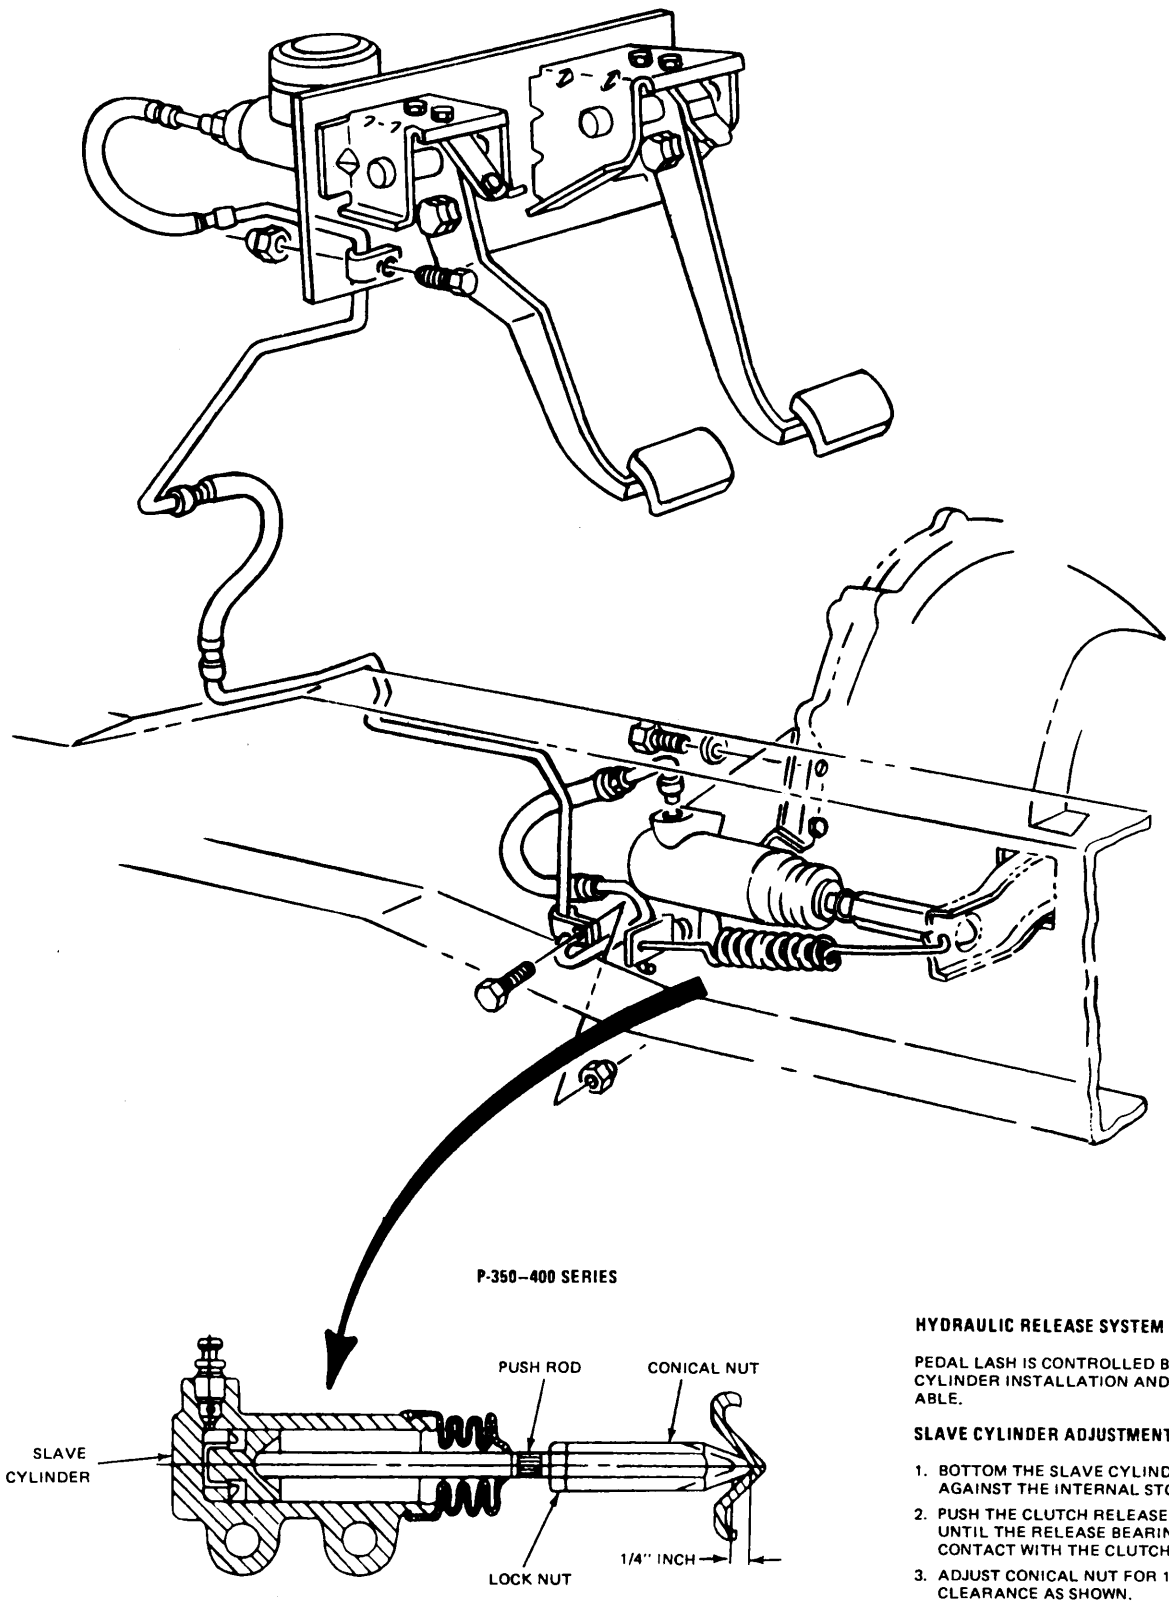
PRESSURE TANK BLEEDING

1. Connect a transparent bleeder hose to the pressure tank hose connector. Attach the bleeder hose to the slave cylinder bleeder screw and fill the empty cylinders.
2. Adjust the pressure tank fluid flow so that the master cylinder does not fill too fast. The C-Series cylinder can be filled faster than the P model master cylinders since the relief port is much larger. Too fast a flow rate will cause spillage, because a stream of fluid will be expelled from the small relief port of conventional type cylinders.
3. Close the bleeder screw on the slave cylinder when the fluid in the master cylinder reservoir is approximately 1/2 inch from the top. No further bleeding should be necessary, since all the air in the system would exhaust through the master cylinder relief port.
4. Check the slave cylinder push rod total travel, which should be at least 1 1/8 inch.

The clutch master cylinder relief port must be open in order to bleed the system. Clutch master cylinder push rod lash of 1/4 inch is required on the P-500 series vehicles to permit the conventional type master cylinder piston to return to the piston stop ring and open the relief port. The clutch master cylinder cannot be adjusted on the P-350 and 400 series vehicles. In C-Series master cylinders, the O-ring seal on the end of the push rod must not seat against the piston. Uncovering of the piston port is accomplished by adjustment of the push rod to a piston lash of 1/4 inch. Forcing the clutch pedal to compress the pedal bumper more than normal by jamming a screwdriver between the pedal pad and the floor insures a complete uncovering of the relief port.

GRAVITY BLEEDING METHOD

1. Attach a funnel to a transparent bleeder hose. Attach the hose to the bleeder screw of the slave cylinder. The funnel must be higher than the master cylinder. Pour hydraulic fluid in the funnel as the system is filling. Do not agitate the fluid more than necessary in order to prevent air bubbles forming in the fluid.
2. Repeat steps 3 and 4 as for pressure tank bleeding. **Note: The funnel method requires caution to prevent air entering the fluid as the system is being filled.**



HYDRAULIC RELEASE SYSTEM ADJUSTMENT

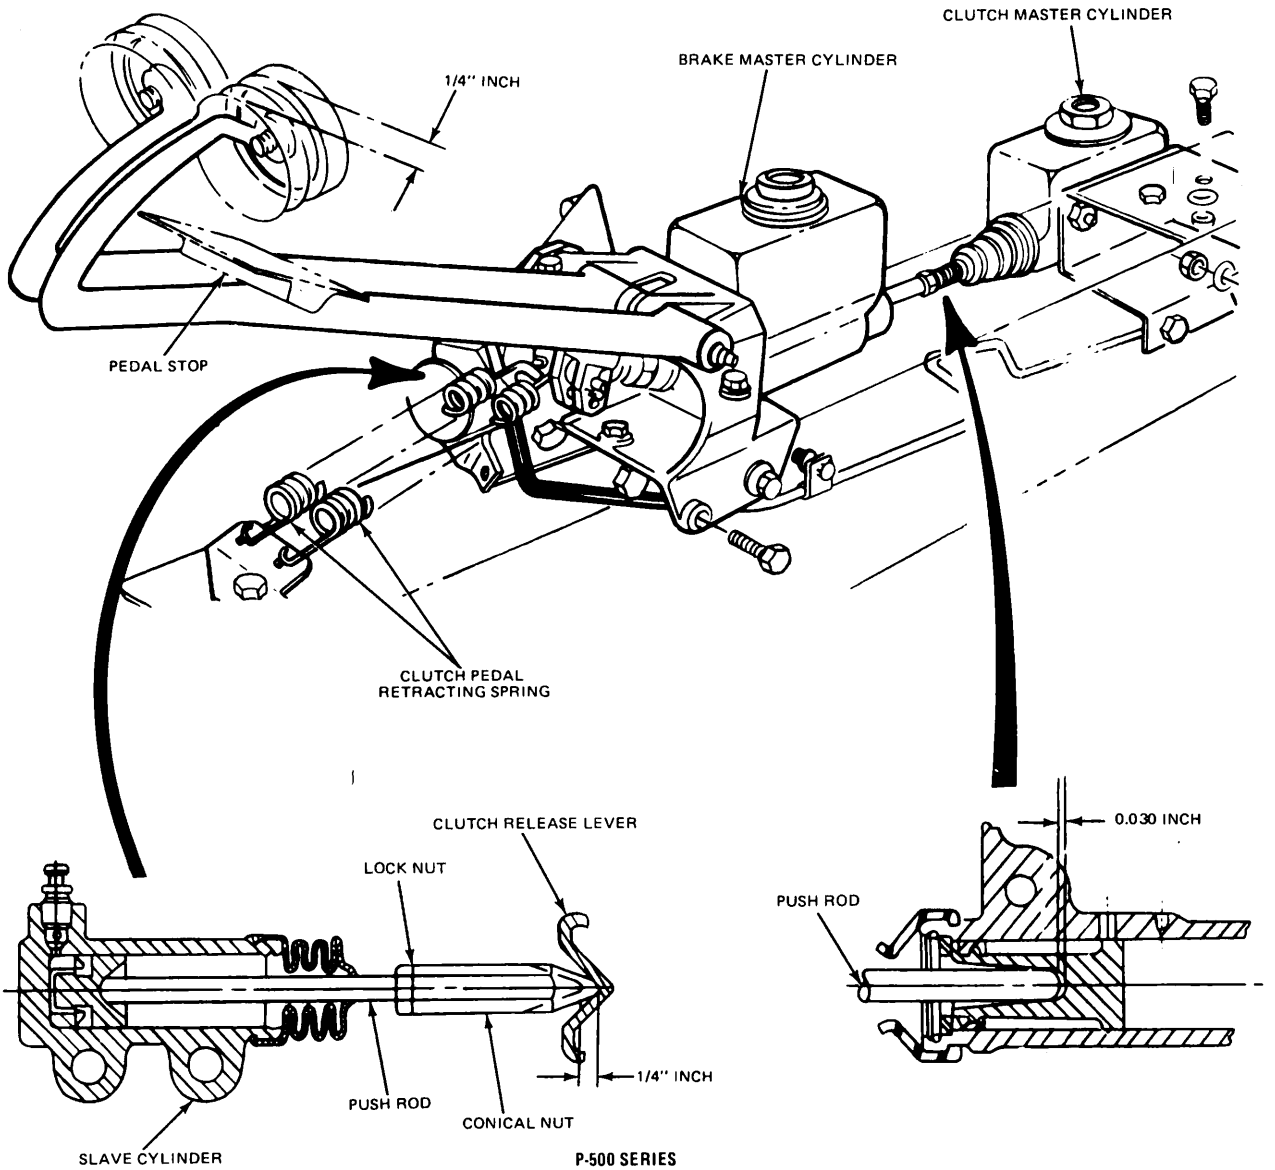
PEDAL LASH IS CONTROLLED BY THE MASTER CYLINDER INSTALLATION AND IS NOT ADJUSTABLE.

SLAVE CYLINDER ADJUSTMENT

1. BOTTOM THE SLAVE CYLINDER PUSH ROD AGAINST THE INTERNAL STOP.
2. PUSH THE CLUTCH RELEASE LEVER BACK UNTIL THE RELEASE BEARING MAKES CONTACT WITH THE CLUTCH FINGERS.
3. ADJUST CONICAL NUT FOR 1/4 INCH CLEARANCE AS SHOWN.
4. TIGHTEN THE JAM NUT AGAINST THE CONICAL NUT.

C2603-A

FIG. 1 Clutch Free Travel Adjustment—P-350-400

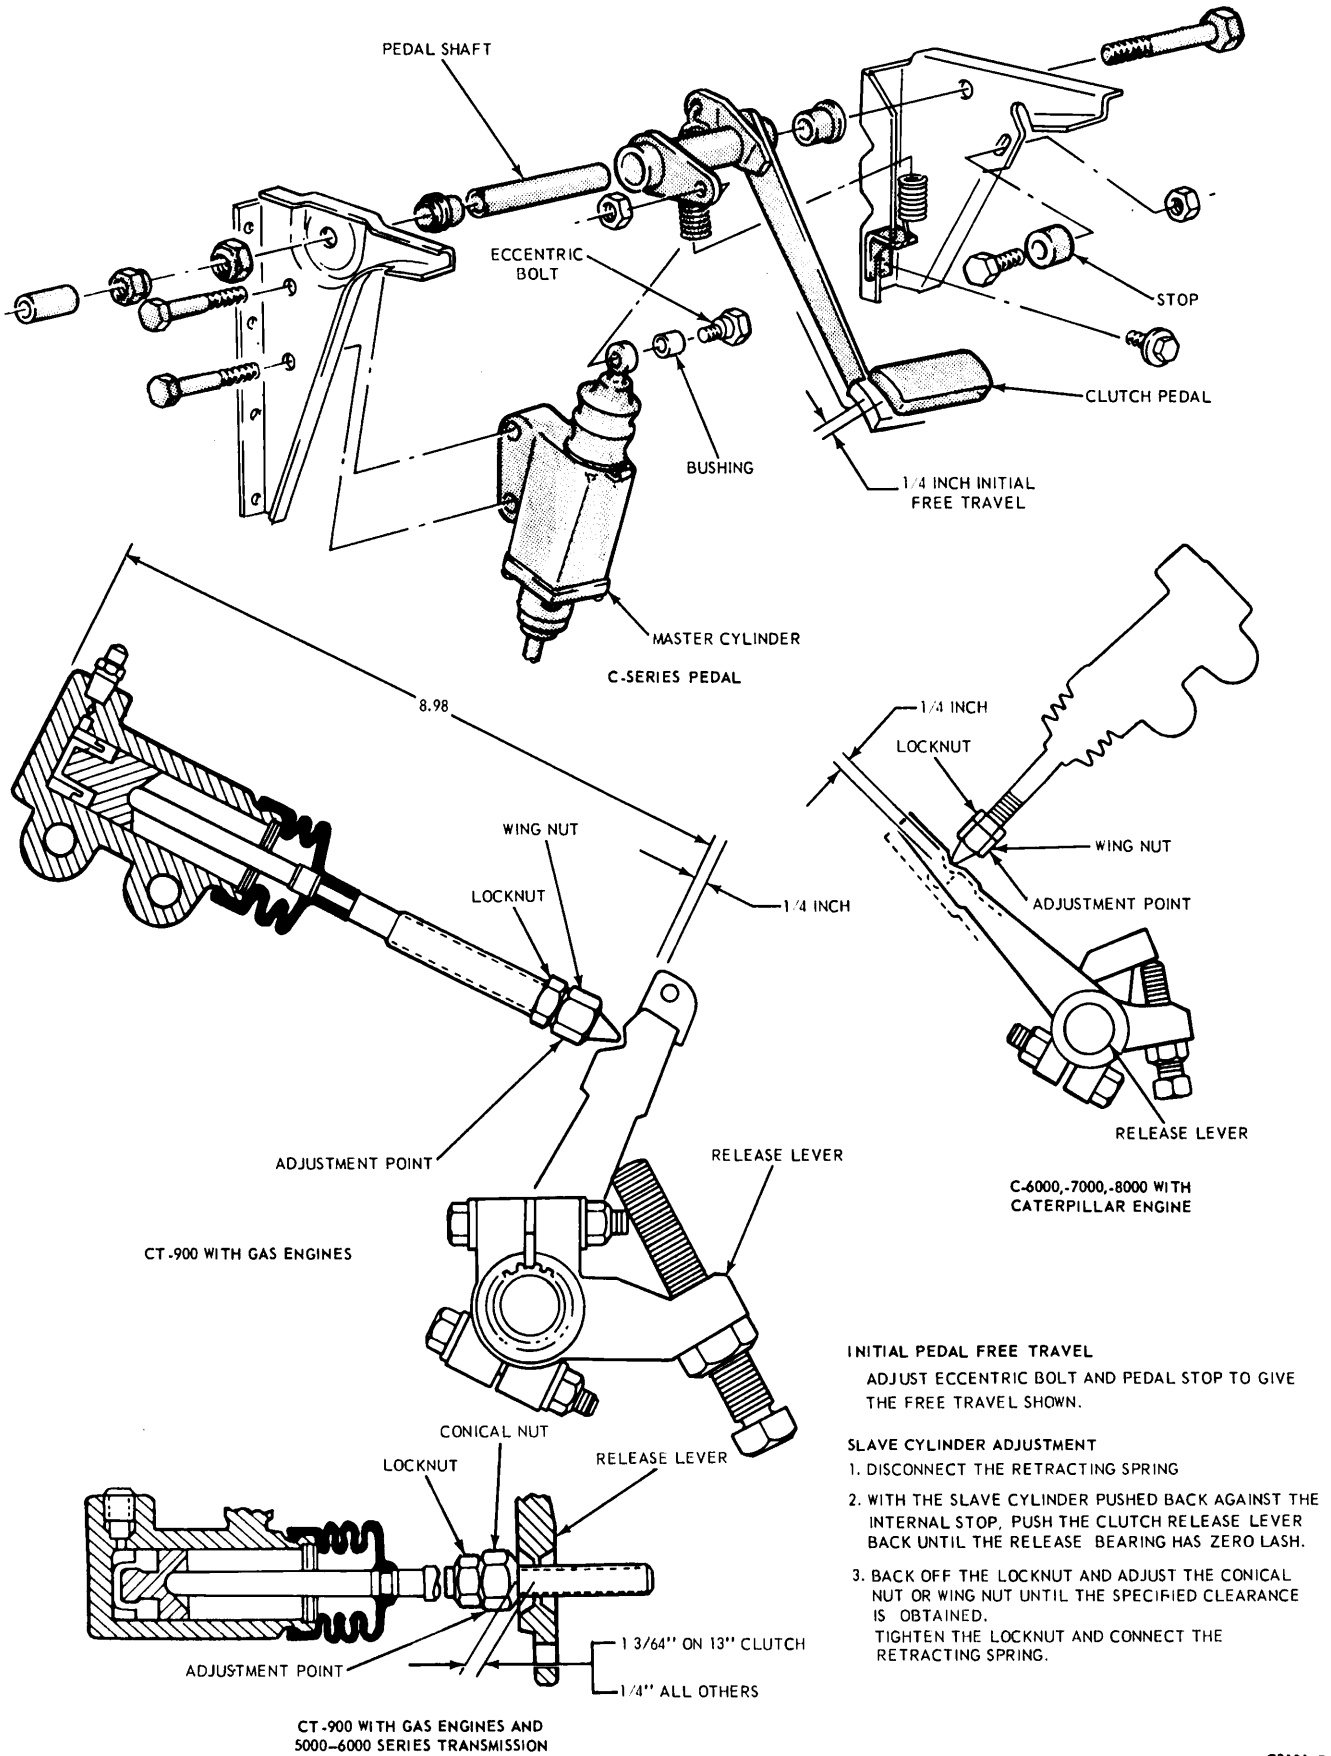


CLUTCH PEDAL AND HYDRAULIC RELEASE SYSTEM ADJUSTMENT

1. WITH RETRACTING SPRING ATTACHED AND THE PEDAL AGAINST STOP, ADJUST THE MASTER CYLINDER PUSH ROD TO GIVE 1/4-INCH FREE PLAY, MEASURED AT THE PEDAL AS SHOWN. (THIS PROVIDES A PUSH ROD CLEARANCE OF 0.030 INCH AT THE PISTON TO ALLOW UNCOVERING OF THE PISTON PORT WHEN THE PEDAL IS IN THE RELEASED POSITION).
2. TIGHTEN THE PUSH ROD JAM NUT SECURELY.
3. WITH THE SLAVE CYLINDER PISTON PUSHED BACK AGAINST THE INTERNAL STOP, PUSH THE CLUTCH RELEASE LEVER BACK UNTIL THE RELEASE BEARING IS AGAINST THE CLUTCH FINGERS.
4. BACK OFF THE JAM NUT AND ADJUST THE CONICAL NUT TO OBTAIN A 1/4-INCH CLEARANCE ON THE RELEASE LEVER AS SHOWN. (THIS ADJUSTMENT PROVIDES AN INTERNAL CLEARANCE OF 0.120 INCHES BETWEEN THE CLUTCH FINGERS AND THE RELEASE BEARING.)
5. TIGHTEN THE JAM NUT AGAINST THE CONICAL NUT.

C2275-B

FIG. 2 Clutch Free Travel Adjustment—P-500



INITIAL PEDAL FREE TRAVEL

ADJUST ECCENTRIC BOLT AND PEDAL STOP TO GIVE THE FREE TRAVEL SHOWN.

SLAVE CYLINDER ADJUSTMENT

1. DISCONNECT THE RETRACTING SPRING
2. WITH THE SLAVE CYLINDER PUSHED BACK AGAINST THE INTERNAL STOP, PUSH THE CLUTCH RELEASE LEVER BACK UNTIL THE RELEASE BEARING HAS ZERO LASH.
3. BACK OFF THE LOCKNUT AND ADJUST THE CONICAL NUT OR WING NUT UNTIL THE SPECIFIED CLEARANCE IS OBTAINED.
   TIGHTEN THE LOCKNUT AND CONNECT THE RETRACTING SPRING.

GENERAL INFORMATION

IDENTIFICATION

See Figure 1 for the codes used to identify the various manual and auxiliary transmissions available in 1972 truck vehicles.

T.R.S. SWITCH

Certain manual transmissions are equipped with a Transmission Regulated Spark switch which signals the distributor spark advance control when the transmission is in high gear. This switch is used on three and four-speed transmissions. A typical Ford 3-speed transmission installation is shown in Fig. 2.

The Ford three-speed transmission T.R.S. switch should not be removed unless it is to be replaced with a new switch because the sealant tape on the switch threads will be damaged. **Never use a gasket with this switch.**

The four-speed T.R.S. switch used in trucks is sealed with a gasket and can be removed and installed without requiring replacement.

DIAGNOSIS

TRANSMISSION

Refer to the Truck Diagnosis Manual for diagnosis information and procedures.

ADJUSTMENTS

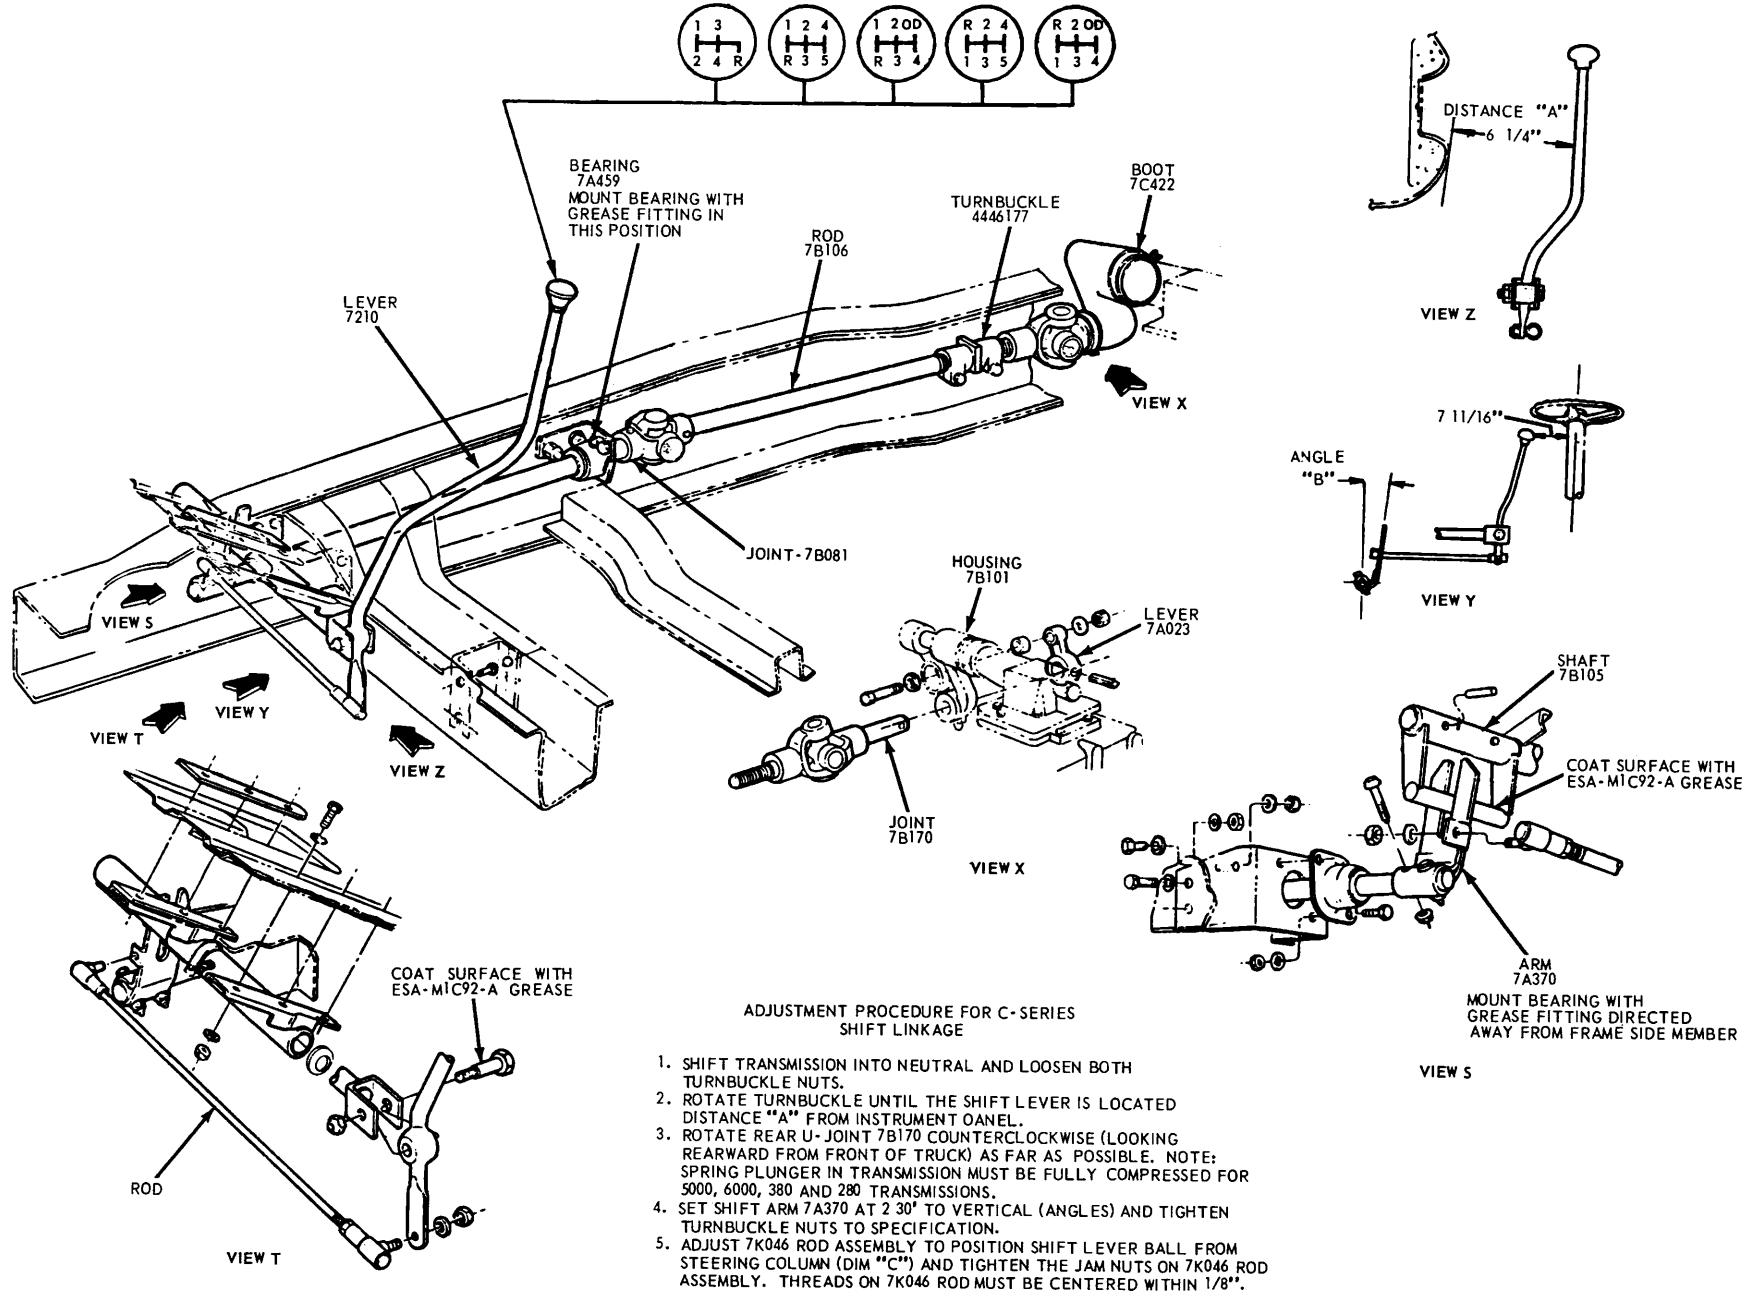
GEAR SHIFT LINKAGE

C-SERIES

Refer to Fig. 3 for instructions on C-Series shift linkage adjustments.

AUXILIARY TRANSMISSION

Refer to Fig. 4 for instructions on adjusting auxiliary transmission shift linkage.



ADJUSTMENT PROCEDURE FOR C-SERIES SHIFT LINKAGE

1. SHIFT TRANSMISSION INTO NEUTRAL AND LOOSEN BOTH TURNBUCKLE NUTS.
2. ROTATE TURNBUCKLE UNTIL THE SHIFT LEVER IS LOCATED DISTANCE "A" FROM INSTRUMENT OANEL.
3. ROTATE REAR U-JOINT 7B170 COUNTERCLOCKWISE (LOOKING REARWARD FROM FRONT OF TRUCK) AS FAR AS POSSIBLE. NOTE: SPRING PLUNGER IN TRANSMISSION MUST BE FULLY COMPRESSED FOR 5000, 6000, 380 AND 280 TRANSMISSIONS.
4. SET SHIFT ARM 7A370 AT 2 30' TO VERTICAL (ANGLES) AND TIGHTEN TURNBUCKLE NUTS TO SPECIFICATION.
5. ADJUST 7K046 ROD ASSEMBLY TO POSITION SHIFT LEVER BALL FROM STEERING COLUMN (DIM "C") AND TIGHTEN THE JAM NUTS ON 7K046 ROD ASSEMBLY. THREADS ON 7K046 ROD MUST BE CENTERED WITHIN 1/8".

FIG. 3 Typical Gear Shift Linkage C-Series

C2607-A

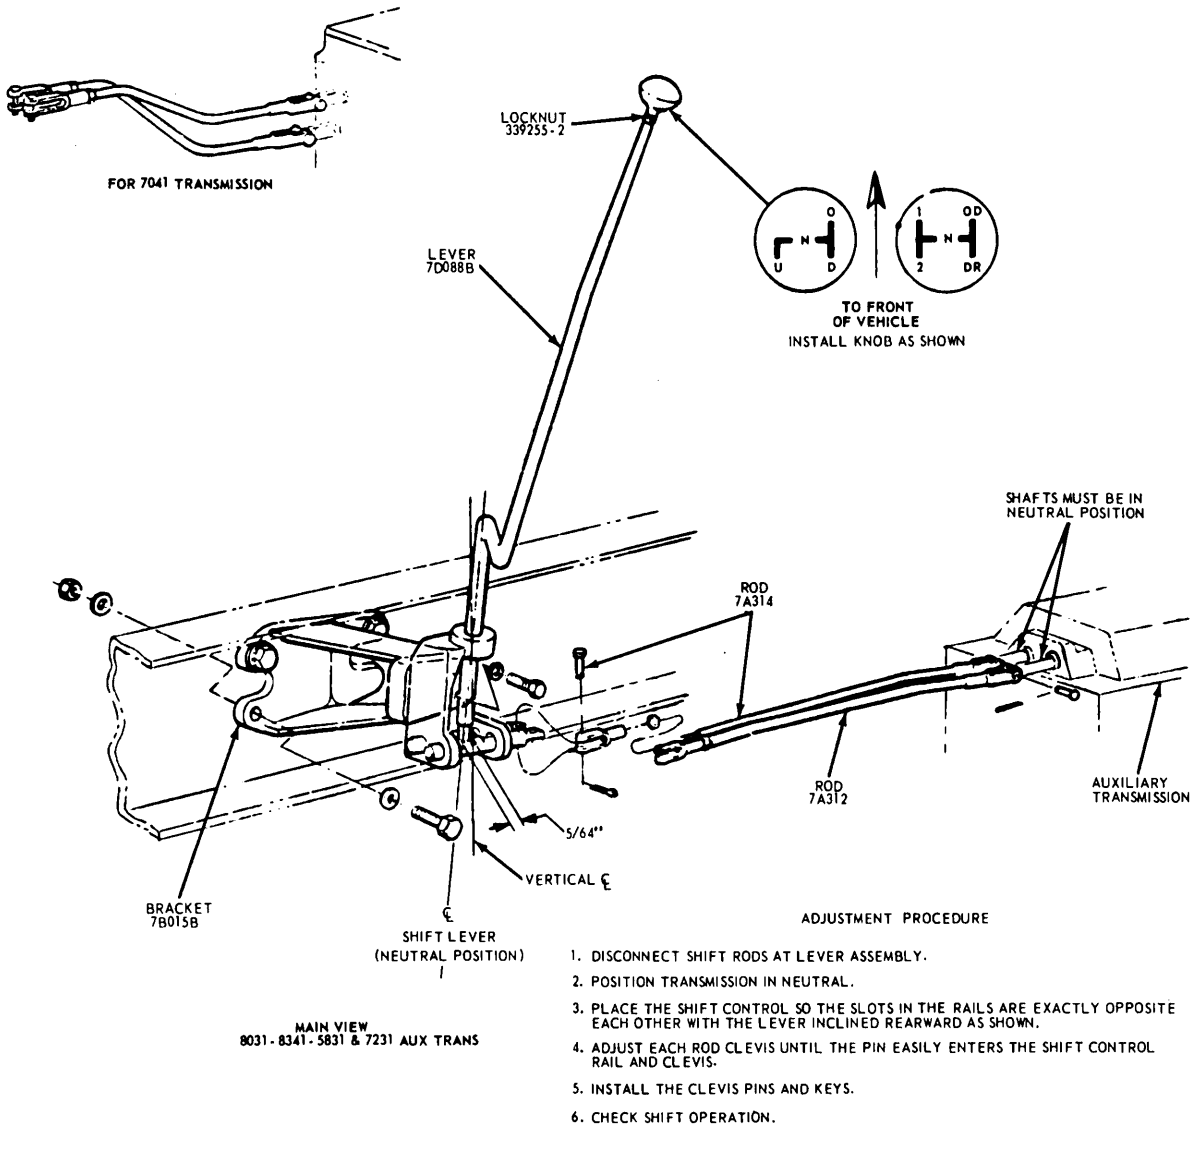


FIG. 4 Typical Auxiliary Transmission Linkage

REMOVAL AND INSTALLATION

GEAR SHIFT LINKAGE

C-SERIES

Removal

1. Disconnect points for this linkage are shown in Fig. 3.

Installation

1. Connection points for this linkage are shown in Fig. 3, along with lubrication and adjustment instructions.

AUXILIARY TRANSMISSION

Removal

Disconnect points for this linkage are shown in fig. 4.

Installation

Connection points and adjustment instructions for this linkage are given in Fig. 4.

REAR CROSS-SHAFT HOUSING AND LINKAGE

Removal

1. Shift the transmission into neutral, remove the protective boot from the linkage, drive out the pin that attaches the U-joint shaft to the lower selector lever (Fig. 3).
2. Remove the lower selector lever from the U-joint shaft, and remove the U-joint.
3. Drive out the pin that holds the upper selector lever on the cross-shaft, and remove the lever.
4. Remove the snap ring from housing bore that holds the shift lever on the cross-shaft. Remove the lever and remove the snap ring from the lever.

5. Remove the bolts that attach the cross-shaft housing on the transmission adapter, and remove the housing by lifting it straight up.
6. After removing the safety wire, loosen the shift finger retaining bolts and remove the cross-shaft and the shift finger.
7. Remove the shift finger Woodruff key from the cross-shaft.

Installation

1. Position the shift finger Woodruff key in the cross-shaft.
2. Position the cross-shaft and the shift finger in the housing.
3. Tighten the shift finger attaching bolts, and install the safety wire.
4. Position the housing on the adapter by lowering the housing vertically, and install the housing bolts. Torque the bolts to specification.
5. Apply Lubriplate or equivalent to the splines on the cross-shaft, the shift lever, and the upper selector lever. Position the snap ring on the shift lever, and position the lever on the cross-shaft. Install the snap ring in the housing bore.
6. Install the upper selector lever on the cross-shaft.
7. Position the U-joint, install the lower selector lever, and lubricate it at all fittings (Fig. 3).
8. Install the protective boot and adjust the linkage.

REAR SEAL

BRONCO, E-100-300, F-100-350 AND P-SERIES

Removal

1. Remove the drive shaft.
2. Remove the seal from the extension housing with the tool shown in Fig. 5.

Installation

1. Install the new seal in the extension housing with the tool shown in Fig. 6. Lubricate the seal with ESA-M1C75B.
2. Install the drive shaft.

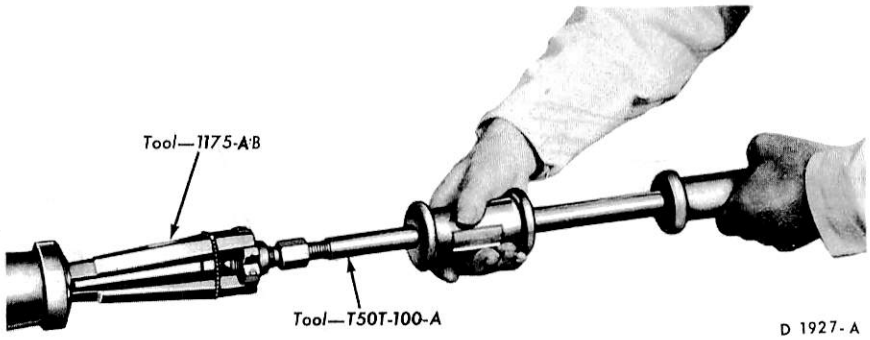

FIG. 5 Removing Extension Housing Seal

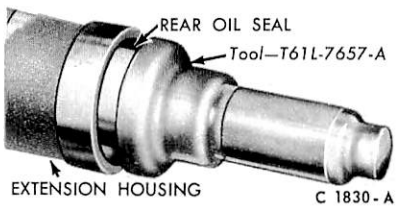

FIG. 6 Installing Extension Housing Seal

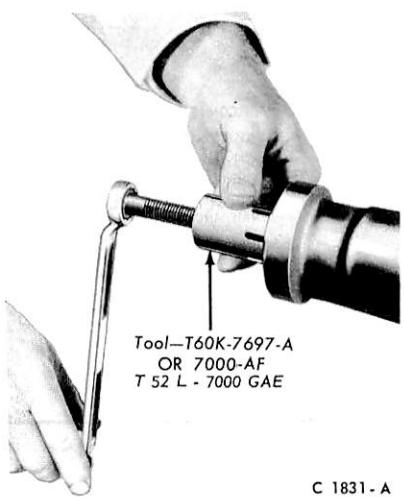

FIG. 7 Removing Extension Housing Bushing and Seal

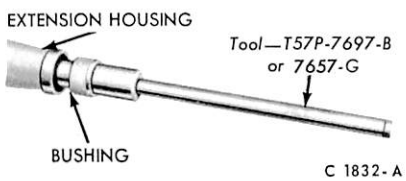

FIG. 8 Installing Extension Housing Bushing

REAR BUSHING AND SEAL

BRONCO, ECONOLINE, E-100-300, F-100-350 AND P-SERIES

Removal

1. Disconnect the drive shaft from the transmission.
2. Insert the tool shown in Fig. 7 into the extension housing until it grips on the front side of the bushing.
3. Turn the screw clockwise until the seal and the bushing are free of the housing.

Installation

1. Lubricate with ESA-M1C75-B; then drive a new bushing into the extension housing with the tool shown in Fig. 8.
2. Install a new seal in the housing as shown in Fig. 6. Lubricate the seal with ESA-M1C75-B.
3. Connect the drive shaft to the transmission.

CLEANING AND INSPECTION

TRANSMISSION

CLEANING

After the transmission has been disassembled, soak the parts except the bearings, in a cleaning solvent until all the old lubricant is dissolved or loosened. Brush or scrape all foreign matter from the parts. Be careful not to damage any of the parts with the scraper.

An excessive amount of foreign material usually results from a bearing failure, gear seizure, tooth breakage, extreme synchronizer wear, or clashing gears. **In such cases, the input and output shaft bearings should be carefully inspected and replaced if necessary. Since countershaft bearings, output shaft pilot bearings, and reverse idler bearings are not so susceptible to damage from foreign material in the lubricant they need not be replaced if they seem satisfactory.**

Wipe the parts or blow compressed air on them until they are thoroughly dry.

To clean the bearings, rotate them in clean solvent until all lubricant is removed. Hold the bearing assembly, to prevent it from rotating and dry it with compressed air.

When the bearings are dry, lubricate them thoroughly with transmission lubricant, and cover them with a clean, lint-free cloth until ready for use.

INSPECTION

Inspect all transmission parts before assembly to determine if they should be replaced.

SUB-ASSEMBLIES

GEAR SHIFT HOUSING

Check the operation and condition of the shift levers, forks and shift rails. If binding occurs when the levers are operated, disassemble the housing assembly, and replace the worn or damaged parts. Lubricate the shift lever ball seat and trunnion with Chassis Lube, Specification ESA-MIC 75-B.

Replace a cover that is bent or distorted. Make sure that the vent hole in the case is open.

TRANSMISSION CASE

Inspect the case for cracks, worn or damaged bearing bores, damaged threads, or other similar damage. If any of these conditions are present, replace the case. Cases may be welded or brazed if the cracks do not extend into bearing bores or bolt holes in machined surfaces.

Holes smaller than 1/4 inch diameter, such as sand holes or casting porosity can be repaired using Metallic Plastic Repair Kit, Part No. C6AZ-19554-A as directed below.

Holes larger than 1/4 inch can be repairedd by drilling, tapping and plugging.

The recommended procedure for using the Metallic Plastic Repair Kit is as follows:

Steam clean the transmission or transfer unit case to remove grease, oil, or road dirt. Clean the repair area thoroughly. Metallic plastic will not

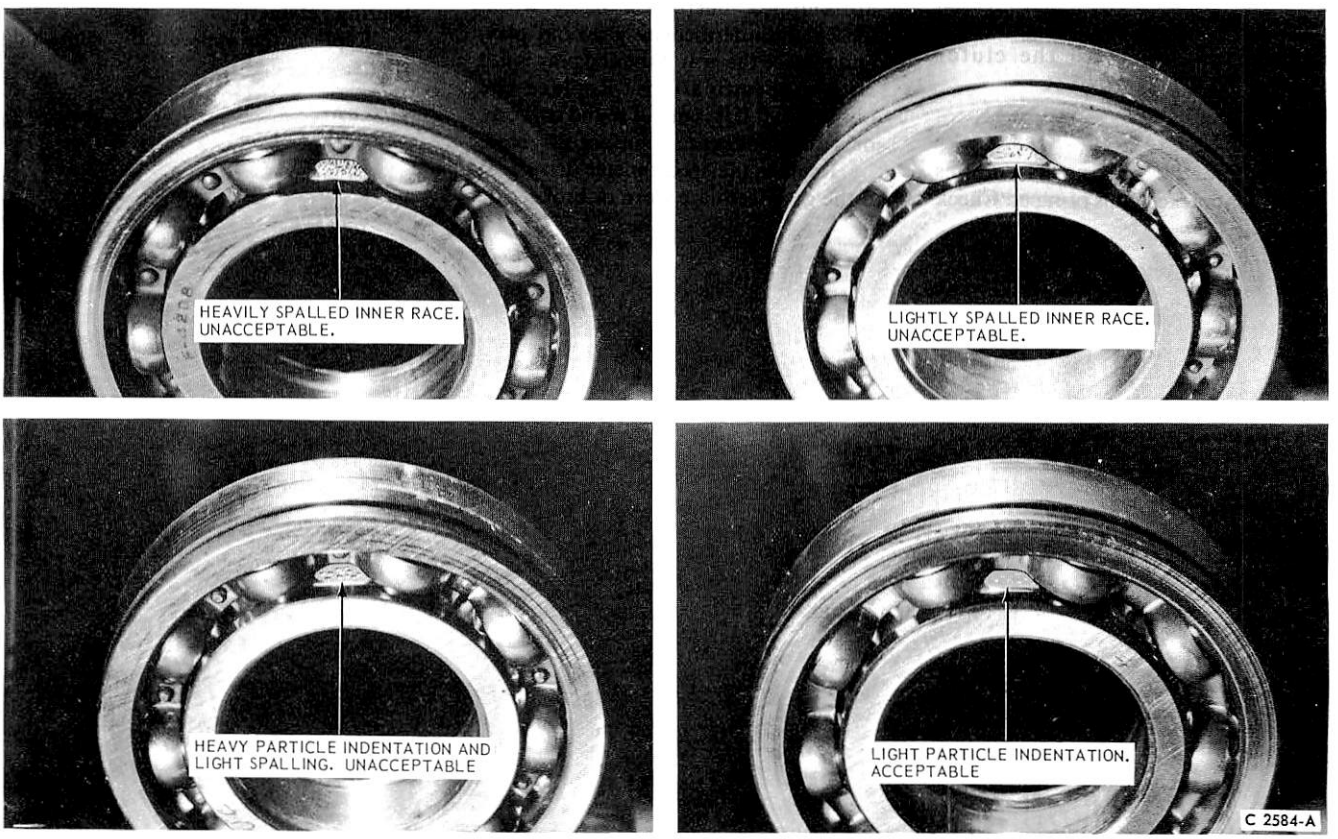

FIG. 9 Ball Bearing Inspection

stick to a dirty or oily surface.

1. Prepare the surface to be repaired by grinding or rotary filing to a clean bright metal surface. Chamfer or undercut the hole or porous area to a greater depth than the rest of the cleaned surface. Solid metal must surround the hole.
2. Mix the metallic plastic base and hardener as directed on the container. Stir thoroughly until uniform.
3. Apply the repair mixture with a suitable clean tool (putty knife, wood spoon, etc.), forcing the epoxy into the hole or porosity.
4. Allow the repair mixture to harden. This can be accomplished by two methods -heat cure with a 250 watt lamp placed 10 inches from the repaired surface, or air dry for 10-12 hours at temperatures above 50 degrees F.
5. Sand or grind the repaired area to blend with the general contour of the surrounding surface.

Do not use this method to repair casting cracks.

Inspect the extension housing seal and bushing or the bearing retainer oil seal. Replace the seal.

Inspect the front face of the case, and file or grind off any minor nicks or burrs that could cause misalignment of the transmission with the clutch housing.

BEARINGS

Examine the bearing assemblies (Fig. 9) for cracked cups or races. Check the races for roughness. Inspect the balls and rollers for looseness, wear, chipping, flaking or other damage. Check the bearings for binding on the shafts or looseness in the bores. If any of these conditions are present, replace the bearings.

COUNTERSHAFT GEAR AND COUNTERSHAFT

Replace the countershaft gear if the teeth are chipped or excessively worn. Replace the countershaft if the shaft is bent or grooved.

REVERSE IDLER GEAR

Replace the reverse idler gear if the gear or bushing is badly worn or if the teeth are chipped or burred. Replace the reverse idler gear shaft if it is excessively worn or scored.

INPUT SHAFT

Replace the input shaft if it is worn, bent, twisted, or if the gear has chipped, worn, or missing teeth, or if the cone surface is damaged. If the pilot bearing bore is scored, replace the gear and gear rollers.

OUTPUT SHAFT

Replace all output shaft gears that are chipped, burred, or badly worn. Check the intermediate gear end play, and replace the gear if the end play is not within specifications. Replace the output shaft if it is out of round or worn, or if the pilot bearing surface is scored.

Replace the speedometer drive gear if the gear teeth are worn or broken. Be sure to install the correct replacement gear.

THRUST WASHERS, SYNCHRONIZER DISCS, BEARING COVERS

Check the surfaces of all thrust washers. Washers scored and/or reduced in thickness should be replaced.

Synchronizer discs scored, burned, or warped should be replaced. Bearing covers grooved or showing wear from the thrust or adjacent bearings should be replaced. Check the oil return threads in the bearing covers. If the sealing action of the threads has been destroyed by contact from the input and output shafts, replace the covers.

SYNCHRONIZER BLOCKING RINGS

Inspect the synchronizer blocking rings for widened index slots, rounded clutch teeth and smooth internal surfaces (must have machined grooves). With the blocker ring on the cone, the distance between the face of the gear must not be less than 0.010 inches.

Check the synchronizer sleeves for free movement on their hubs. Make sure the alignment marks (etched marks) are properly indexed.

Replace the seal in the input shaft bearing retainer.

Replace the seals on the cam and shafts.

SPECIAL SERVICE TOOLS

GENERAL TORQUE SPECIFICATIONS

Unless otherwise specified, the following torque ranges are to be used for fitting or fastener diameters as indicated.			
Bolt or Nut Diameter	**Torque Range**	**Bolt or Nut Diameter**	**Torque Range**
1/4"	85–115 IN-LBS	9/16"	110–150 FT-LBS
5/16"	12–17 FT-LBS	5/8"	150–205 FT-LBS
3/8"	31–42 FT-LBS	3/4"	220–300 FT-LBS
7/16"	50–70 FT-LBS	7/8"	360–480 FT-LBS
1/2"	75–105 FT-LBS	1.0"	540–730 FT-LBS
Above Torque Specifications apply to both Fine and Coarse Threads.

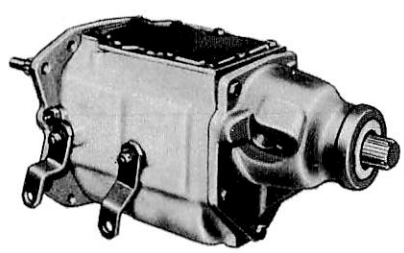
DESCRIPTION

TRANSMISSION

The 3.03 three-speed transmission (Fig. 1) is available in the F-100-250-Series, Econoline and Bronco vehicles.

A transmission service identification tag is located on the right front side of the case (Fig. 2). The tag will show the transmission model and service identification code (when required). The second line will show the transmission serial number.

The transmission is of the fully synchronized type with all gears except the reverse gear and sleeve being in constant mesh. All forward speed changes are accomplished with synchronizer sleeves. The synchronizers permit quicker shifts, greatly reduce gear clash and permit down-shifting from high to intermediate between 40-15 mph and from intermediate to low below 20 mph.



C1838-B

ADJUSTMENTS

GEAR SHIFT LINKAGE

F-100-250

Refer to Figure 4 for adjustment instructions.

BRONCO

Refer to Figure 5 for adjustment instructions.

ECONOLINE

Refer to Figures 3 and 6 for adjustment instructions.

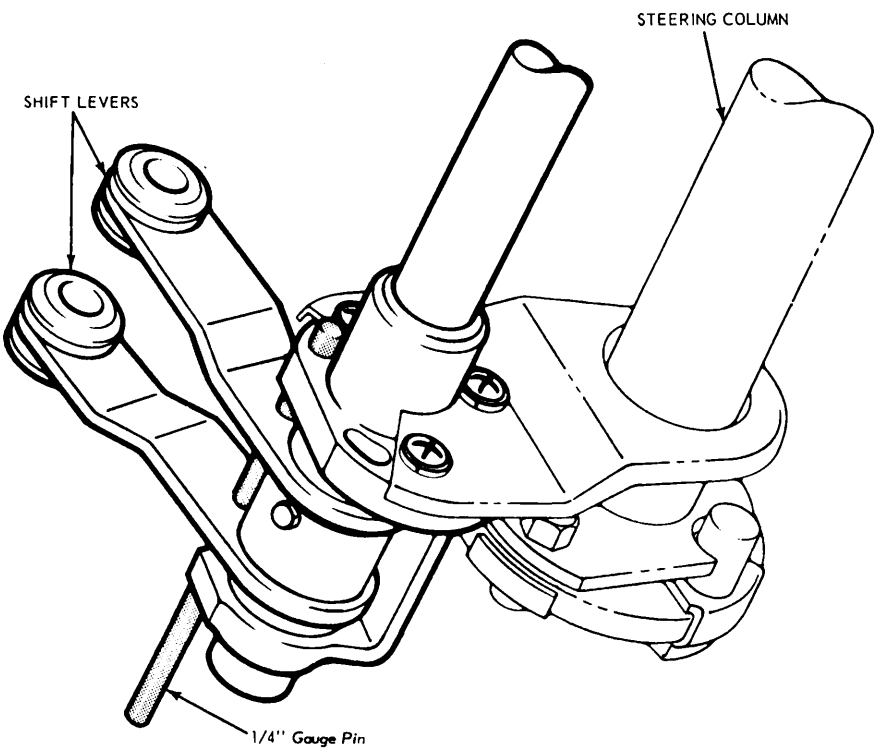

FIG. 3 Gauge Pin Installation—Econoline

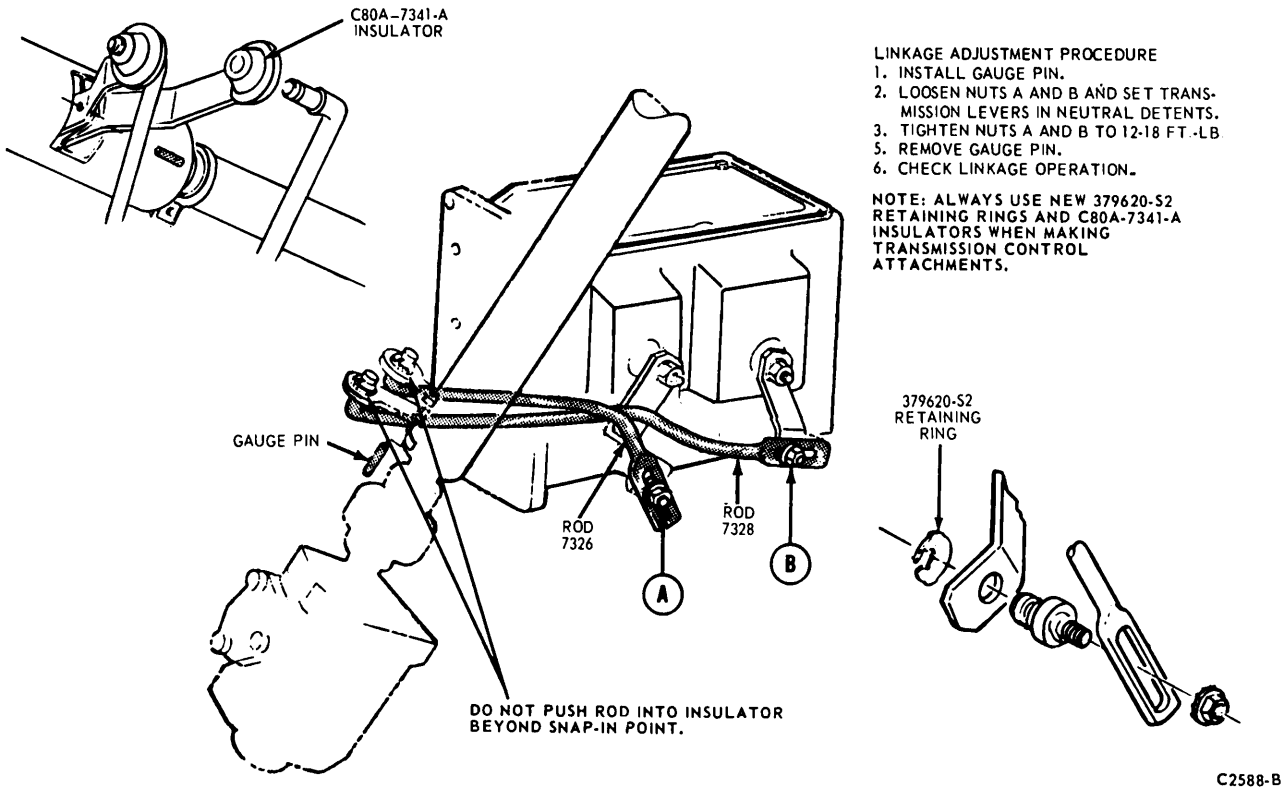

FIG. 4 Gearshift Linkage Adjustment—F-100-250

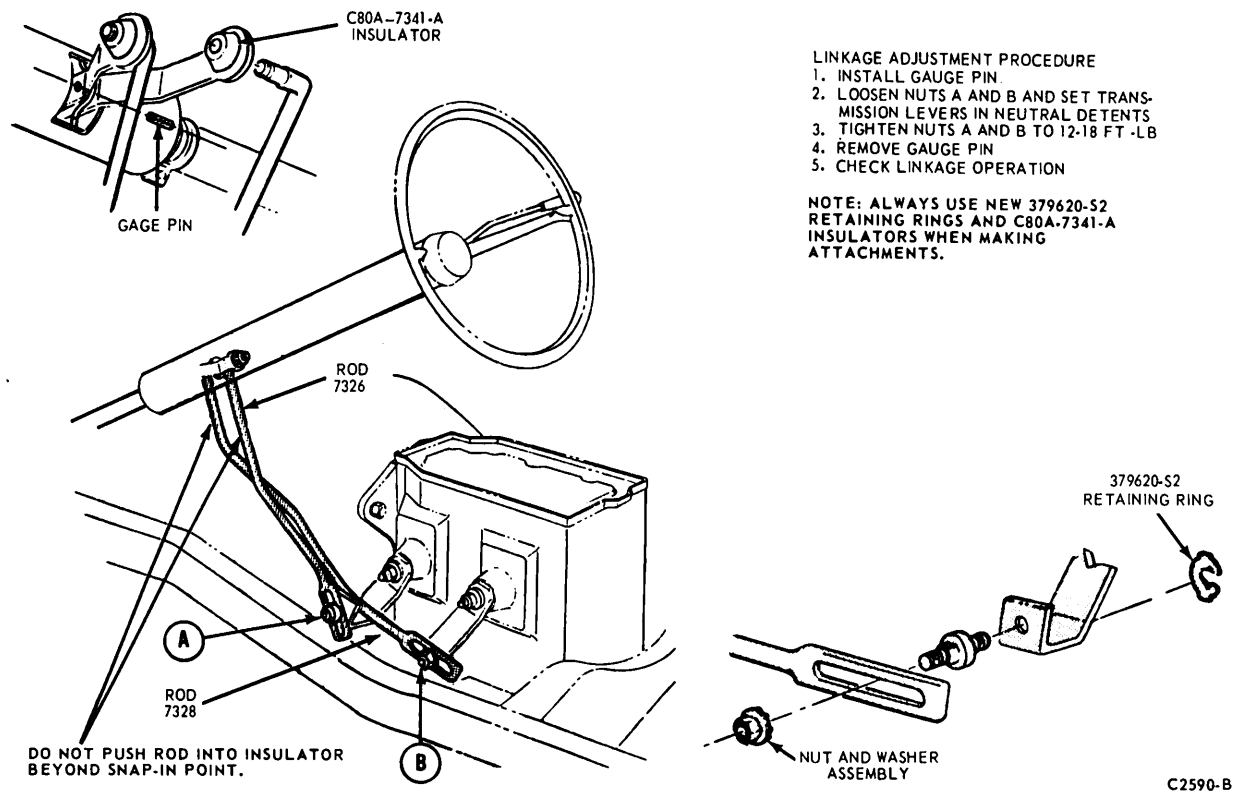

FIG. 5 Gearshift Linkage Adjustment—Bronco

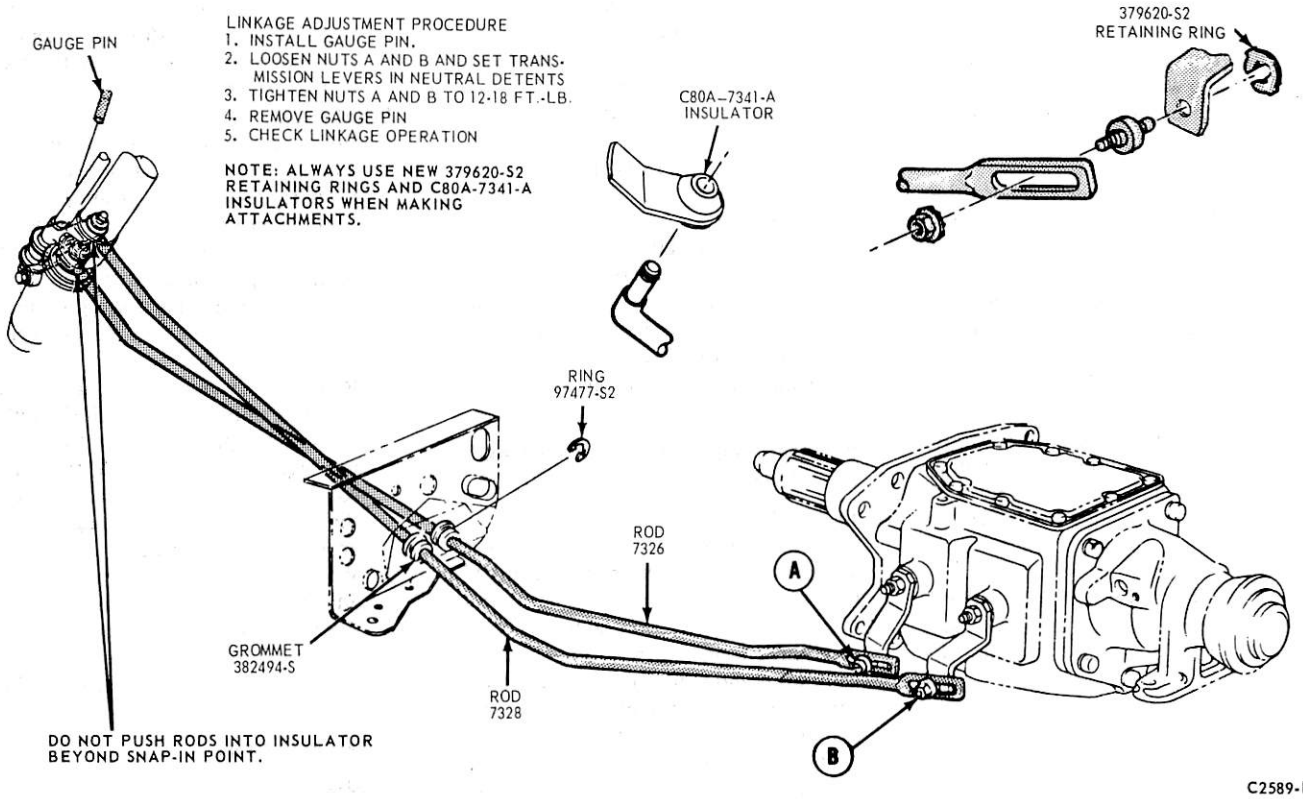

FIG. 6 Gearshift Linkage Adjustment—Econoline

REMOVAL AND INSTALLATION

GEAR SHIFT TUBE

ECONOLINE

Removal

1. Disconnect the horn and turn signal wires. Remove the steering wheel.
2. Fold the floor mat back, remove the steering column floor cover retaining screws, the steering column floor cover and position the rubber weather seal out of the way.
3. Remove the selector lever roll pin and disconnect the selector lever at the lever socket.
4. Working under the hood, remove the windshield washer reservoir to gain access to the shift levers.
5. Remove the shift rod metal retainers from the shift rods. Remove the shift rods from the shift levers.
6. Working inside the vehicle, remove the three bolts retaining the shift lever bracket to the steering column lower bracket (Fig. 7). Lift the shift tube clear of the steering column.
7. Remove the clamp bolt and five attaching bolts from the steering column lever retainer and remove the retainer from the column. Loosen the steering column-to-instrument panel clamp attaching bolts.
8. Remove the snap ring from he steering shaft upper bearing.
9. Pull the steering column up just enough to disengage the shift tube at the upper end of the column. Lift the shift tube out of the vehicle.
10. Remove the lock screw from the shift tube and align the slot in the cross-over sleeve with the cross-over pin.
11. Remove the cross-over pin from the shift lever retaining bracket and slide the shift tube out of the bracket.
12. Remove the cross-over sleeve, shift levers, spring washer and bushings from the shift lever retaining bracket (Fig. 8).

Installation

1. Insert bushing into the upper portion of the shift lever retaining bracket (shift lever side).
2. Assemble the two shift levers, cross-over sleeve, two bushings and spring washer as a sub-assembly (Fig. 8).
3. Position sub-assembly in the shift lever retaining bracket. Insert shift tube through shift lever retaining bracket and the sub-assembled

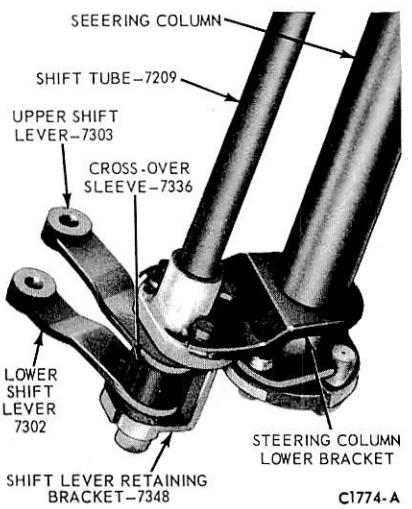

FIG. 7 Shift Tube and Levers—Econoline

parts, positioning spring washer from inside shift lever bracket hole.
4. Align the cross-over pin hole in the shift tube with the hole in the cross-over sleeve and the notches in the shift levers. Insert the cross-over pin.
5. Rotate the cross-over sleeve so that the lock screw hole in the shift tube is aligned with the notch in the cross-over sleeve. Insert the lock screw into hole and tighten. This will keep the cross-over pin in position.
6. Position the shift tube on the steering column. Lift the column up just enough to fit the shift tube into its seat in the column upper flange. Slide the column back into position and install the snap ring (bevel side up) on the steering shaft upper bearing.
7. Position the lower end of the tube in the steering column lower bracket. Install the three bolts attaching the shift lever retaining bracket to the steering column lower bracket.
8. Position the rubber weather seal and the steering column lower retainer on the floor pan and install the clamp bolts and the five retaining bolts. Do not tighten the retaining bolts at this time.
9. Check for free rotation of the steering shaft. Torque the steering column lower retaining attaching bolts to specification. Tighten the steering column-to-instrument panel clamp attaching bolts.
10. Connect the shift rods to the shift levers.
11. Install the windshield washer reservoir.
12. Position the selector lever in its socket and install the roll pin.
13. Install the steering wheel and connect the horn and turn signal wires. Check the operation of the horn and turn signals.
14. Adjust the shift linkage as outlined in this section.

COLUMN-MOUNTED SHIFT LINKAGE GROMMET

Removal

The column-mounted shift lever assembly incorporates an oil impregnated plastic grommet in the end of each lever arm. A special tool (Fig. 9) is required to install the grommet in the shift lever, and to install the shift linkage rod into the grommet. Remove and install the grommet as follows:

1. Place the lower jaw of the tool between the shift lever and the shift rod. Position the stop pin against the end of the shift rod (Fig. 9) and force the rod out of the grommet. Remove the grommet from the shift lever by cutting off the large shoulder with a sharp knife. **The grommet must be removed from the shift lever and a new one installed each time the rod is disconnected.**

Installation

1. Before installing a new grommet, adjust the stop pin as necessary to properly install the grommet and coat the outside of the grommet with lubricant. Then, place the grommet on the stop pin and force it into the shift lever hole. Turn the grommet several times to be sure it is properly seated.
2. Readjust the stop pin to a length which is sufficient to install the shift rod into the grommet (Fig. 9). If the pin height is not adjusted, the shift rod may be pushed too far through the grommet, causing damage to the grommet retaining lip.
3. With the pin height properly adjusted, position the shift rod on the tool and force the rod into the grommet until the groove in the rod seats on the inner retaining lip of the grommet.

TRANSMISSION

F-100-250

Removal

1. Raise the vehicle and position safety stands. Support the engine with a jack and wood block placed under the oil pan.

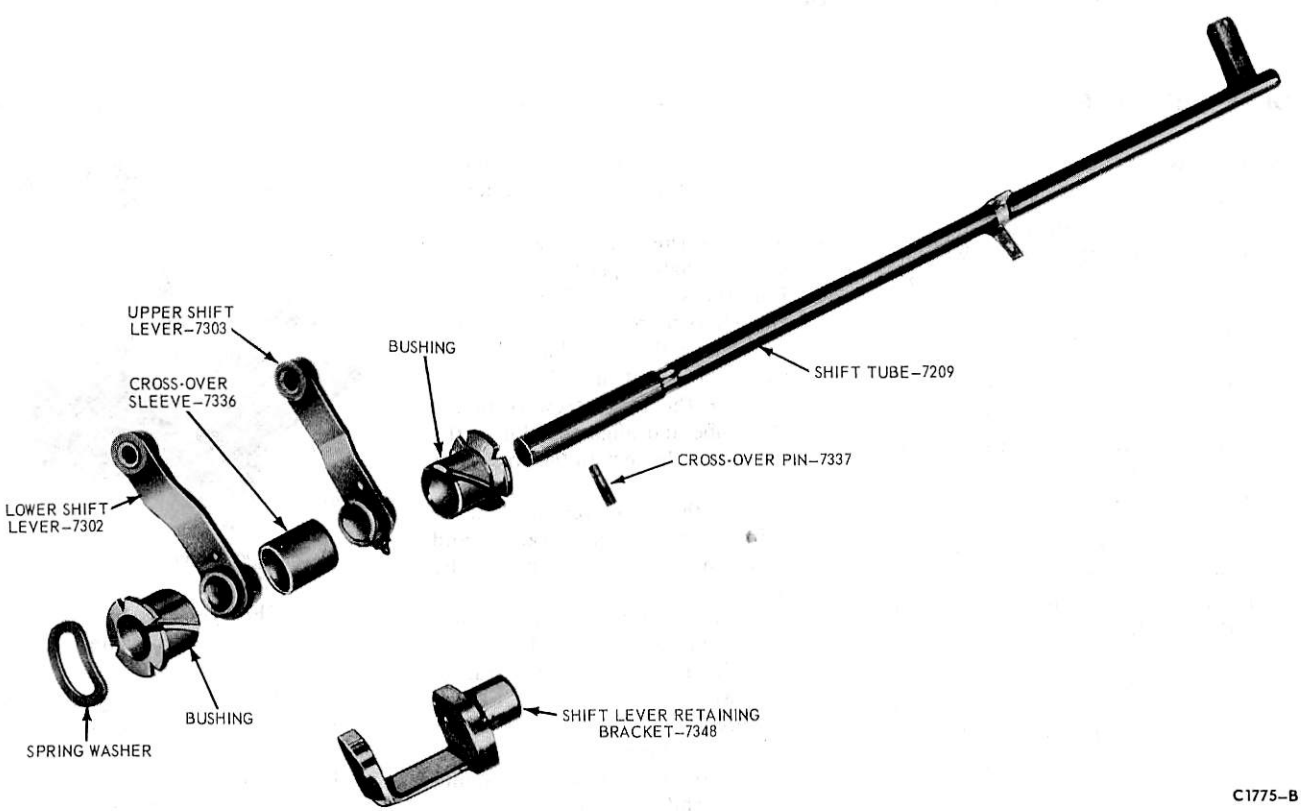

FIG. 8 Shift Levers Disassembled Econoline

2. Drain the transmission lubricant by removing the lower extension housing-to-transmission bolt.
3. Position a transmission jack under the transmission.
4. Disconnect the gear shift linkage at the transmission.
5. If the vehicle has a four-wheel drive, remove the transfer case shift lever bracket from the transmission.
6. Disconnect the speedometer cable.
7. Disconnect the T.R.S. switch wire if so equipped.
8. Disconnect the drive shaft from the transmission as detailed in Group 15.
9. Raise the transmission if necessary and remove the rear support (Figs. 10 and 11).
10. Remove the transmission-to-clutch housing attaching bolts.
11. Move the transmission to the rear until the input shaft clears the clutch housing and lower the transmission.

Do not depress the clutch pedal while the transmission is removed.

Installation

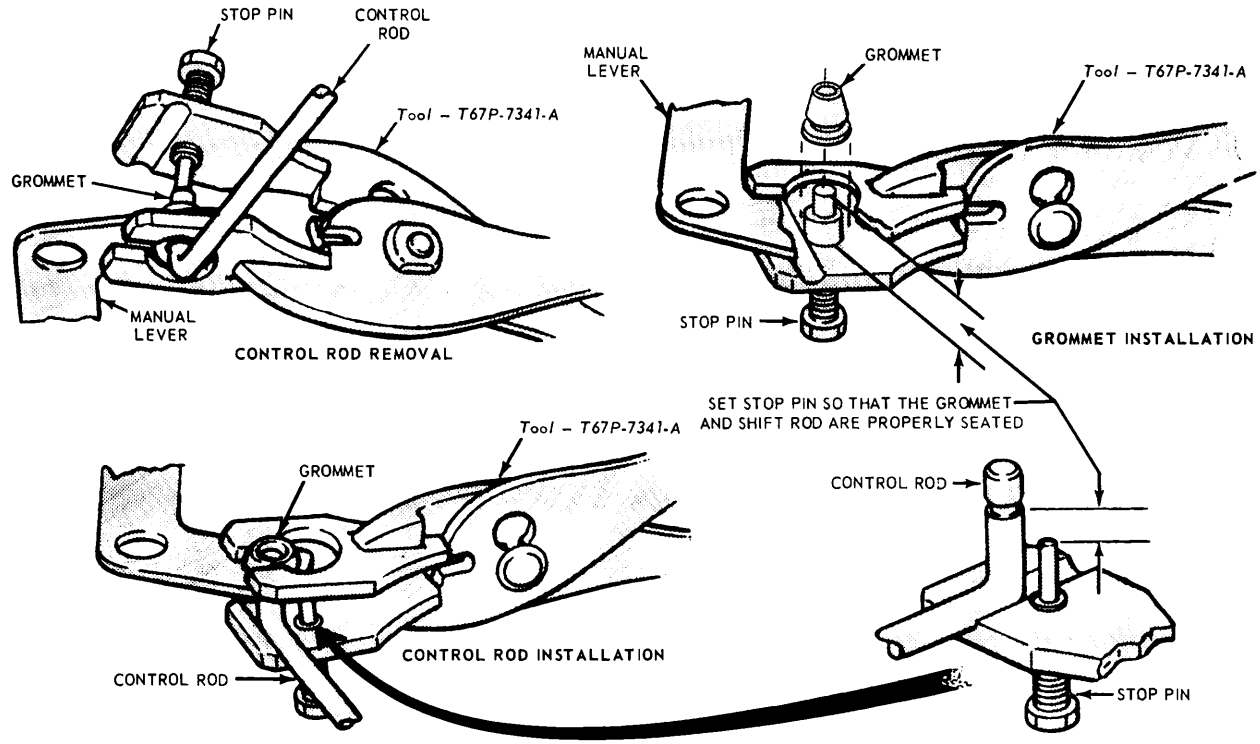
Before installing the transmission, apply a light film of lubricant (C1AZ-19590-B) to the release bearing inner hub surfaces, release lever fulcrum and fork and the transmission front bearing retainer. Exercise care to avoid contaminating the clutch disc with excessive grease.

1. Place the transmission on a transmission jack. Raise the transmission until the input shaft splines are in line with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork.
2. Install a guide stud in each lower clutch housing-to-transmission case mounting bolt and align the splines on the input shaft with the splines on the clutch disc.
3. Slide the transmission forward on the guide studs until it contacts the clutch housing.
4. Install the two transmission to flywheel housing upper mounting bolts and nuts. Remove the two guide studs and install the lower mounting bolts. Torque the four mounting bolts to specifications. Install the rear support and torque the attaching bolts and nuts to specifications (Figs. 10 and 11). Remove the transmission jack and engine jack.
5. Connect the speedometer cable and the driven gear.
6. Connect the T.R.S. switch wire if so equipped.
7. Install the drive shaft as detailed in Group 15.
8. Connect each shift rod to its respective lever on the transmission.
9. If the vehicle is equipped with four-wheel drive, install the four wheel drive shaft bracket and torque the bolts to specifications.
10. Fill the transmission to the proper level with an approved lubricant.
11. Adjust the clutch pedal free travel and shift linkage as required.

ECONOLINE

Removal

1. Raise the vehicle on a hoist and drain the lubricant from the transmission by removing the lower extension housing-to-transmission bolt.
2. Disconnect the drive shaft from the flange at the transmission. Secure the front end of the drive shaft out of the way with lock wire.
3. Disconnect the speedometer cable from the extension housing and disconnect the gear shift rods from the transmission shift levers.
4. Disconnect the T.R.S. switch wire if so equipped.
5. Position a transmission jack under the transmission. Secure the transmission to the jack.
6. Raise the transmission slightly and remove the four bolts retaining the transmission support crossmember to the frame side rails. Remove the bolt retaining the transmission extension housing to the crossmember.



C 2090-A

FIG. 9 Removing or Installing Shift Linkage Grommet

7. Remove the four transmission-to-flywheel housing bolts.
8. Position engine support bar (Tool T65E-6000-J) to the frame (Fig. 12).
9. Lower the transmission.

Installation

1. Make certain that the machined surfaces of the transmission case and the flywheel housing are free of dirt, paint and burrs.
2. Install a guide pin in each lower mounting bolt hole.
3. Start the input shaft through the release bearing. Align the splines on the input shaft with the splines in the clutch disc. Move the transmission forward on the guide pins until the input shaft pilot enters the bearing or bushing in the crankshaft. If the transmission front bearing retainer binds up on the clutch release bearing hub, work the release bearing lever until the hub slides onto the transmission front bearing retainer. Install the two transmission-to-flywheel housing upper mounting bolts and lock washers. Remove the two guide pins and install the lower mounting bolts and lock washers. Torque the four mounting bolts to specifications.
4. Raise the jack slightly and remove the engine support bar.
5. Position the support crossmember on the frame side rails and install the retaining bolts. Install the extension housing-to-crossmember retaining bolt. Torque all retaining bolts to specification.
6. Connect the gear shift rods and the speedometer cable.
7. Connect the T.R.S. switch if so equipped.
8. Install the drive shaft and torque the attaching bolts to specification.
9. Fill the transmission to the bottom of the filler hole with the recommended lubricant.
10. Adjust the clutch pedal free travel and shift linkage as required.

BRONCO

Removal

1. Shift the transfer case into neutral.
2. Remove the bolts attaching the fan shroud to the radiator support.
3. Raise the vehicle on a hoist.
4. Support the transfer case shield with a jack and remove the bolts that attach the shield to the frame side rails. Remove the shield.
5. Drain the transmission and transfer case lubricant. To drain the transmission lubricant, remove the lower extension housing-to-transmission bolt.

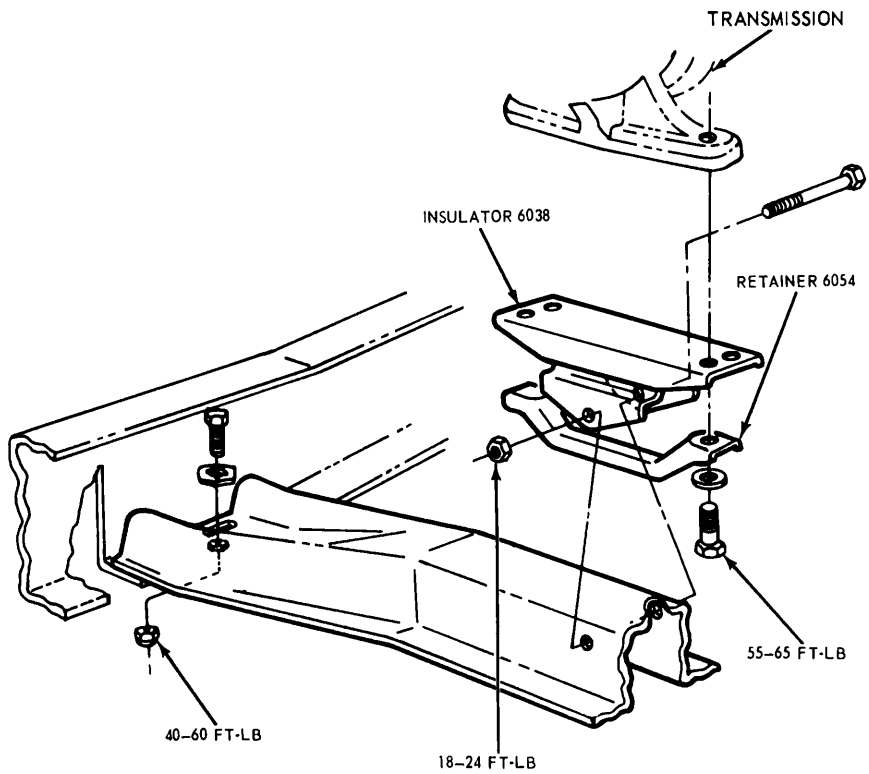


FIG. 10 Removing and Installing Crossmember-F-100-250

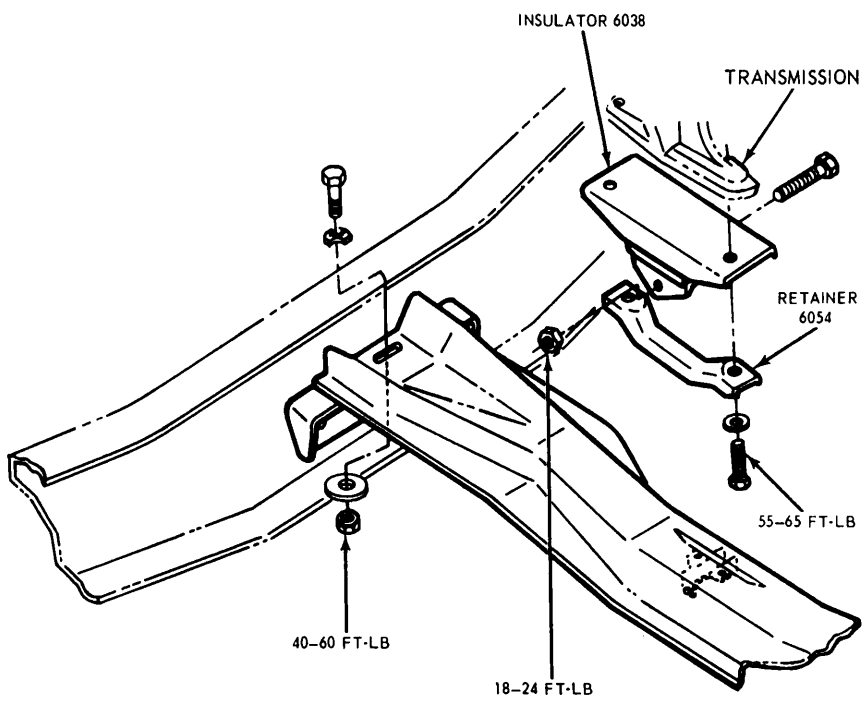

FIG. 11 Removing and Installing Crossmember—F-250 W/140" W.B.

6. Disconnect the front and rear drive shafts at the transfer case. (Fig. 13).
7. Disconnect the speedometer cable at the transfer case.
8. Disconnect the T.R.S. switch if so equipped.
9. Disconnect the shift rods from the transmission. shift levers. Place the first-reverse gear shift lever into the first gear position and insert the fabricated tool (Fig. 14). This tool will prevent the input shaft roller bearings from dropping into the transmission case when separating the transfer case from the transmission and output shaft.
10. Support the engine with a jack.
11. Remove two cotter pins, bolts, washers, plate and insulators that secure the crossmember to the transfer case adapter.
12. Remove the crossmember-to-frame side support attaching bolts.
13. Position a transmission jack under the transfer case. Raise the transmission and transfer case and remove the upper insulators from the crossmember. Remove the crossmember.
14. Roll back the boot enclosing the transfer case shift linkage. Remove the threaded cap holding the shift lever assembly to the shift bracket. Remove the shift lever assembly.
15. Remove the two lower bolts attaching the transmission to the flywheel housing.
16. Reposition the transmission jack under the transmission and secure with the chain.
17. Remove the two upper bolts securing the transmission to the flywheel housing. Move the transmission and transfer case rearward and downward out of the vehicle.
18. Move the assembly to a bench and remove the transfer case-to-transmission attaching bolts.
19. Slide the transmission assembly off the transfer case.

Installation

1. Position transfer case to transmission, apply C9AZ-19554-A sealer to bolt threads and install attaching bolts. Torque bolts to specifications.
2. Position the transmission and transfer case on a transmission jack and secure with the safety chain.
3. Raise the transmission and transfer case assembly into position and install the transmission case to the flywheel housing.
4. Install the two upper and two lower transmission attaching bolts and torque to specifications.
5. Position the transfer case shift lever and install the threaded cap to the shift bracket. Reposition the rubber boot.
6. Raise the transmission and transfer case high enough to provide clearance for installing the crossmember. Position the upper insulators to the crossmember and install the crossmember-to-frame side support attaching bolts. Torque to specifications (Fig. 13).
7. Align the bolt holes in the transfer case adapter with those in the crossmember, then lower the transmission and remove the jack.
8. Install the crossmember-to-transfer case adapter bolts, nuts, insulators, plates and washers. Torque the nuts to specifications (Fig. 13). Secure the nuts with cotter pins.
9. Remove the engine jack.
10. Remove the fabricated tool and connect each shift rod to its respective lever on the transmission. Refer to Part 16-11 for rod adjustment instructions.
11. Connect the speedometer cable.

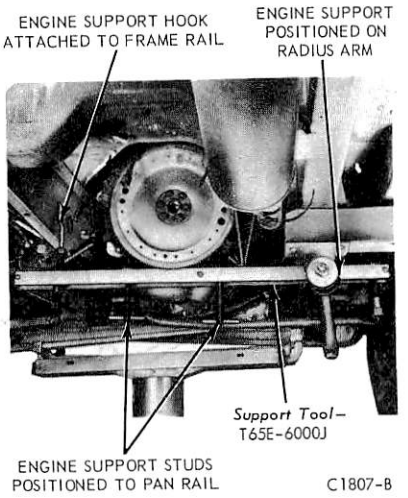

FIG. 12 Installing Engine Support Bar—Econoline

12. Connect the T.R.S. switch if so equipped.
13. Install the rear axle drive shaft to the transfer case. Torque the attaching bolts to specifications (Fig. 13).
14. Install the front wheel drive shaft to the transfer case. Torque the attaching bolts to specifications (Fig. 13).
15. Fill the transmission and transfer case to the bottom of the filler hole with the recommended lubricant.
16. Position the transfer case shield to the frame side rails and install the attaching bolts.
17. Lower the vehicle.
18. Install the fan shroud.
19. Check transfer case operation.

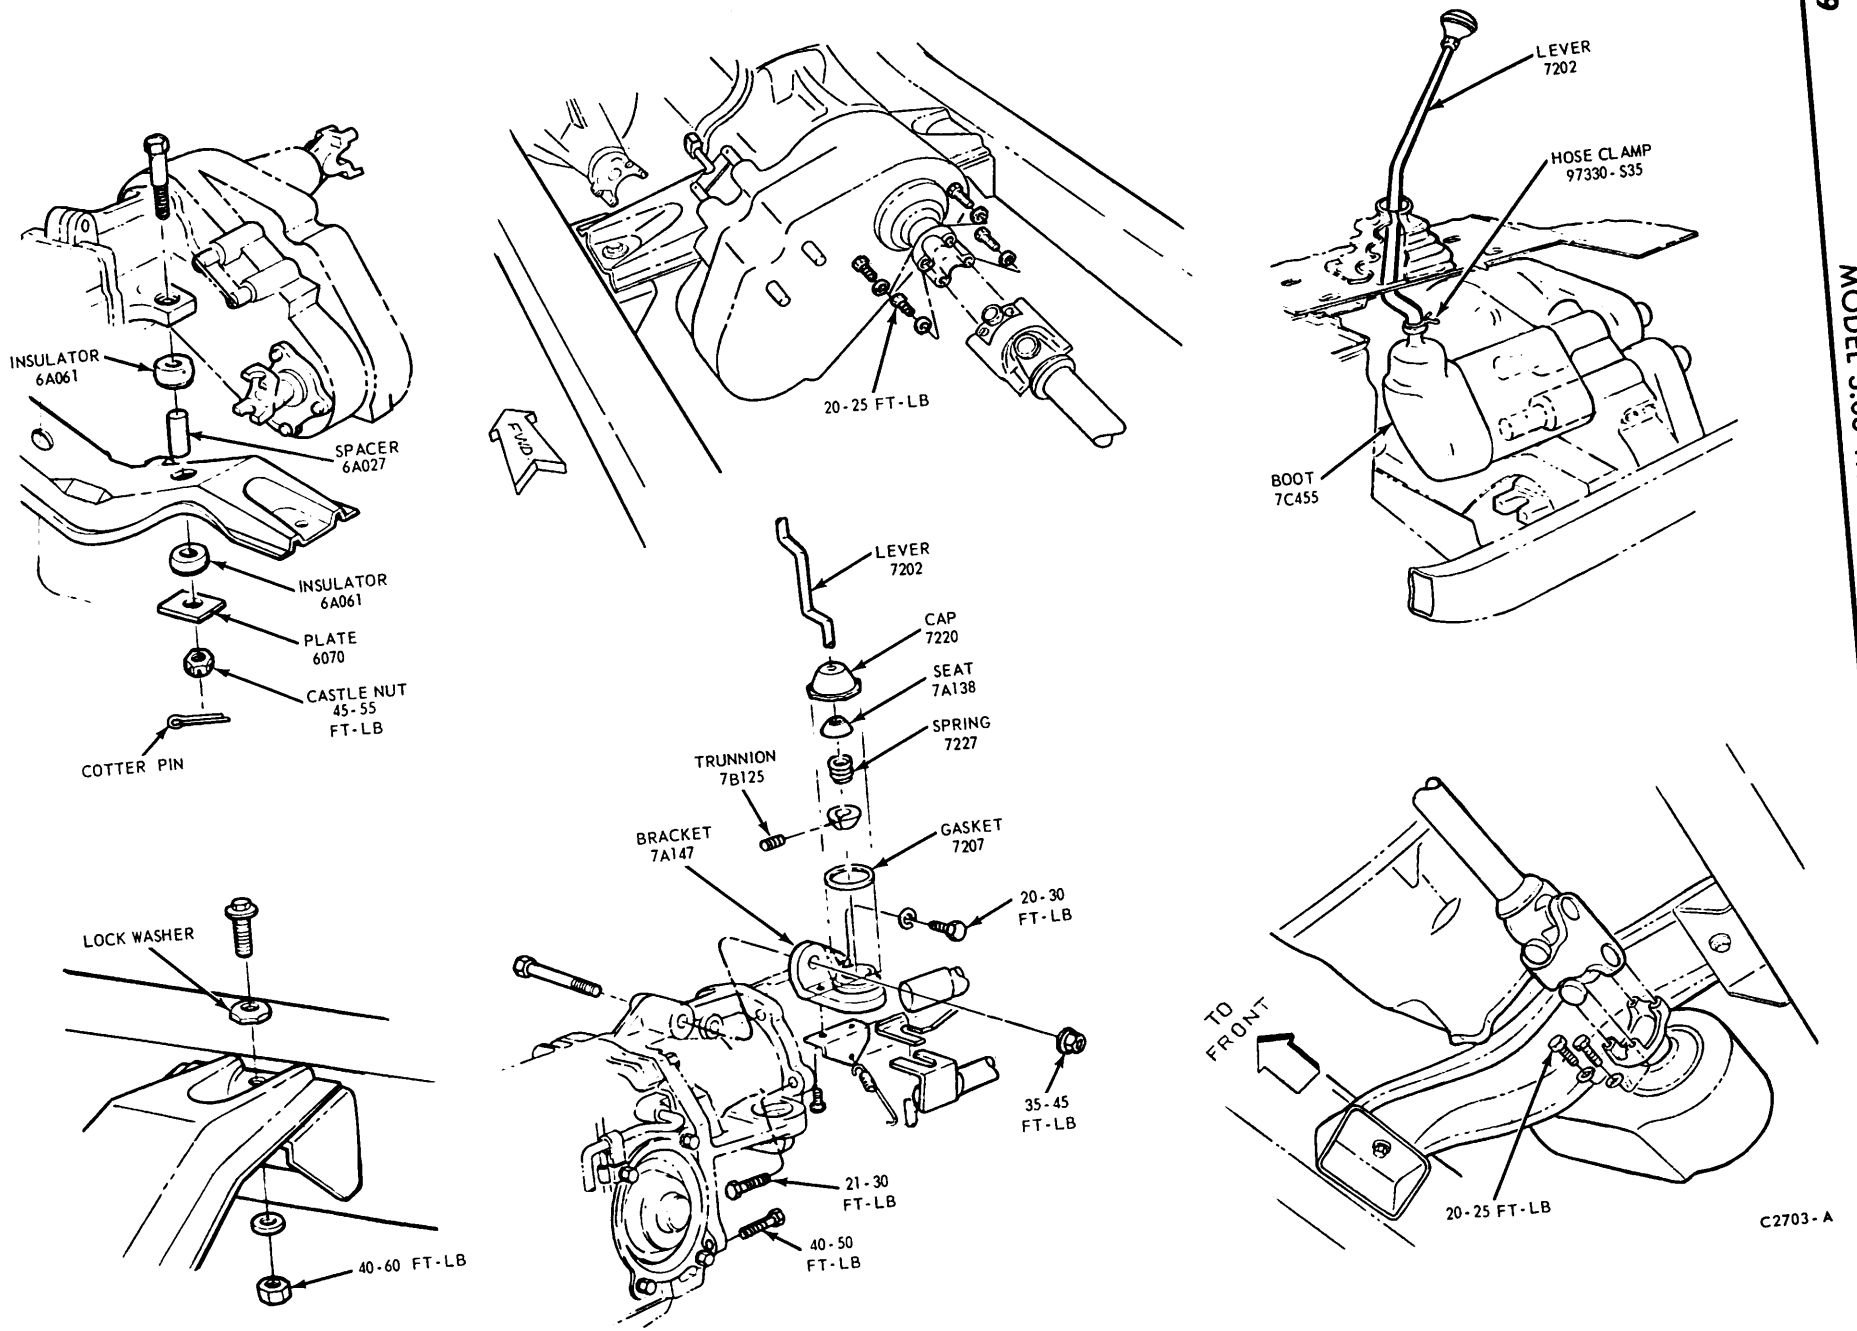

FIG. 13 Transfer Case Installation

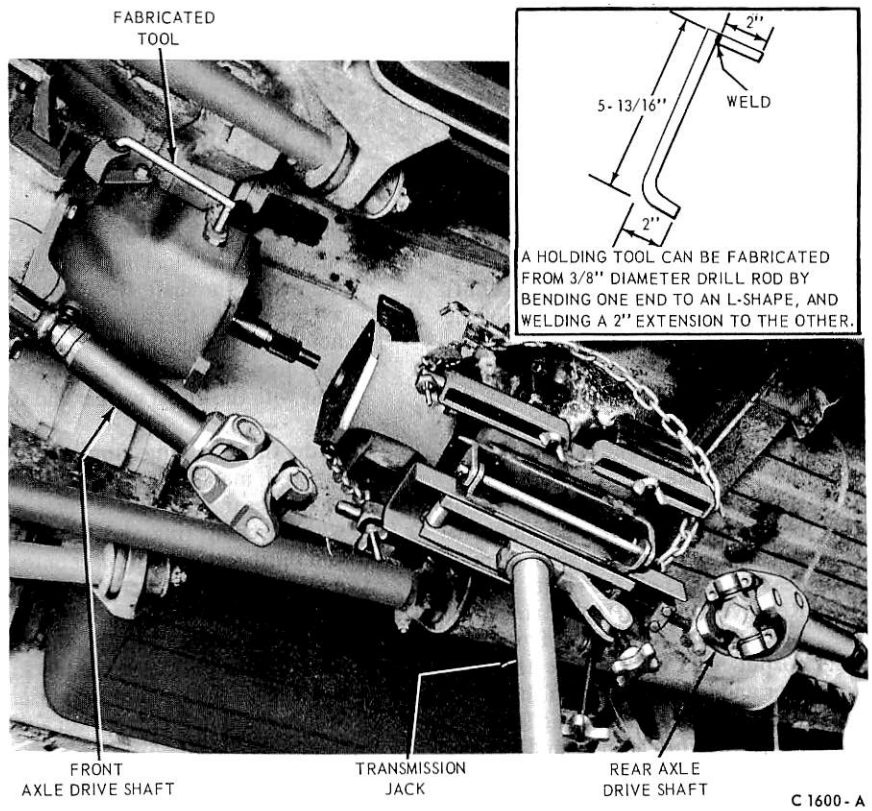

FIG. 14 Removing or Installing Transfer Case—Bronco-Manual Transmission

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Mount the transmission in a holding fixture and drain the lubricant by removing the lower extension housing bolt.
2. Remove the capscrews that attach the cover to the case. Remove the cover and the gasket (Fig. 11) from the case.
3. Remove a long spring that retains the detent plug in the case (Fig. 20). Remove the detent plug with a small magnet.
4. Remove the capscrews and lock washers that attach the extension housing to the case. Remove extension and gasket from the case.
5. Remove the capscrews and lock washers that attach the front bearing retainer to the case. Remove the front bearing retainer and gasket from the case.
6. Remove the lubricant filler plug from the right side of the case. Working through the plug opening, drive the roll pin out of the case and countershaft with 1/4 inch punch (Fig. 16).
7. Hold the countershaft gear with a hook and with the tool shown in Fig 17 push the countershaft out the rear of the case.

The countershaft (cluster) gear and thrust washers (Fig. 13) can now be lowered to the bottom of the case.

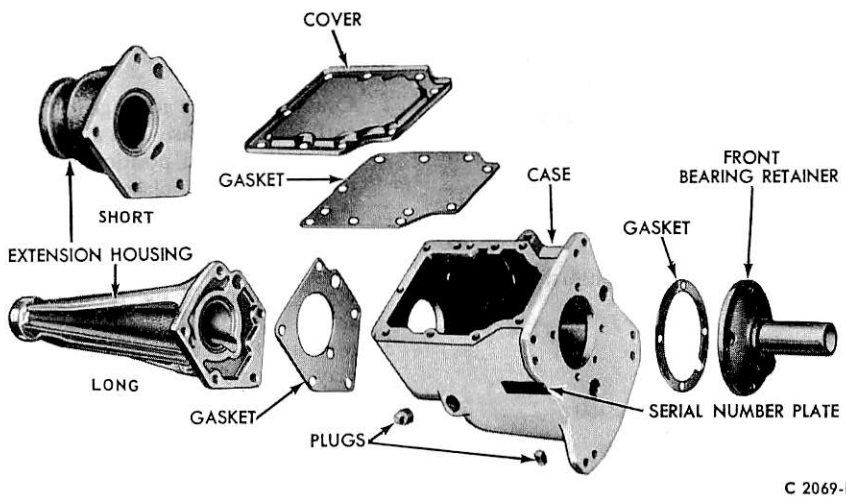

FIG. 15 Transmission Case and Related Parts

Remove the countershaft from the rear of the case.

8. Remove the snap ring that secures the speedometer drive gear on the output shaft. Slide the speedometer drive gear off the shaft. Remove the speedometer drive gear lock ball from the shaft.
9. Remove the snap ring that retains the output shaft bearing on the shaft. Remove the bearing from the case and shaft as shown in Fig. 18.
10. Place both shift levers in the neutral (center) position.
11. Remove the set screw that secures the first and reverse shift fork to the shift rail. Slide the first and reverse shift rail out through the rear of the case.
12. Slide the first and reverse synchronizer forward as far as possible, and rotate the first and reverse shift fork upward. Then lift it from the case.
13. Move the second and third-speed shift fork to the second-speed position to gain access to the set screw. Remove the set screw from the fork. Rotate the shift rail 90 degrees as shown in Fig. 19.
14. Lift the interlock plug (Fig. 20) from the case with a magnet.
15. Tap on the inner end of the second and third-speed shift rail to remove the expansion plug (Fig. 20) from the front of the case. Remove the shift rail.
16. Remove the second and third-speed shift rail detent plug and spring from the detent bore.
17. Pull the input gear and shaft from the case.
18. Rotate the second and third-speed shift fork upward, and lift it from the case.
19. Carefully lift the output shaft assembly out through the top of the case.
20. Lift the reverse idler gear and two thrust washers (Fig. 21) from the case. Lift the countershaft gear, thrust washer, and dummy shaft from the case.
21. Remove the snap ring from the front of the output shaft, and slide the synchronizer and the second-speed gear (Fig. 22) off the shaft.
22. Remove the next snap ring and tabbed thrust washer from the output shaft. Then slide the first gear and blocking ring off the shaft.
23. Remove the next snap ring from the output shaft. The first and reverse synchronizer hub is a press fit on the output shaft. To eliminate the possibility of damaging the synchronizer assembly, remove the synchronizer hub using an Arbor Press as shown in Fig. 23. **Do not attempt to remove or install the hub by hammering or prying.**
24. **Do not remove the T.R.S. switch from the case, if so equipped, unless the switch is damaged. Removal of the switch will damage the plastic sealing tape.**

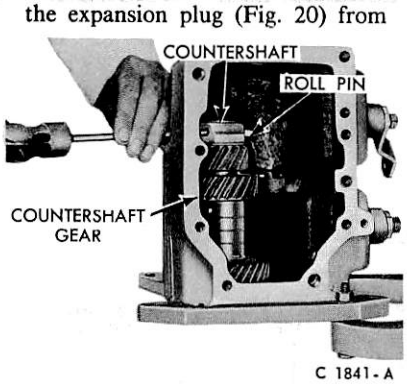

FIG. 16 Removing Countershaft Roll Pin

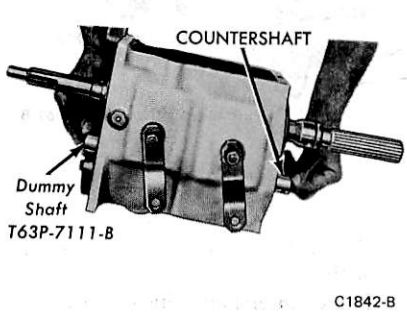

FIG. 17 Removing Countershaft

Assembly

1. Coat the reverse idler gear thrust surfaces in the case with a thin film of lubricant and position the two thrust washers in place.
2. Position the reverse idler gear and shaft in place. Align the gear bore and thrust washers with the case bores and install the reverse idler shaft.
3. Measure the reverse idler gear end play with a feeler gauge. End play should be within specification. If the end play is not within specification, replace the thrust washers. If the end play is within limits, leave the reverse idler gear installed.
4. Lubricate the output shaft splines and machined surfaces with transmission lubricant.
5. The first and reverse synchronizer hub is a press fit on the output shaft. To eliminate the possibility of damaging the synchronizer assembly, install the synchronizer hub with the teeth end of the gear facing toward the rear of the shaft, using an Arbor Press as shown in Fig. 23. **Do not attempt to remove or install the hub by hammering or prying.**
6. Place the blocking ring on the tapered machined surface of the first gear.
7. Slide the first gear onto the output shaft with the blocking ring toward the rear of the shaft. Rotate the gear as necessary to engage the three notches in the blocking ring with the synchronizer inserts. Secure the first gear with the thrust washer and snap ring.
8. Slide the blocking ring onto the tapered machined surface of the second gear. Slide the second gear with blocking ring and the second and third gear synchronizer onto the mainshaft. The tapered machined surface of the second gear must be toward the front of the shaft. Make sure that the notches in the blocking ring engage the synchronizer inserts. Secure the synchronizer with a snap ring.
9. Coat the bore of the input shaft and gear with a **thin** film of grease. **A thick film of grease will plug the lubricant holes and prevent lubrication to the bearings.** Install the 15 bearings (Fig. 26) in the bore.
10. Install the input shaft through the front of the transmission. Install the snap ring in the bearing groove.
11. Position the output shaft assembly in the case. Position the second and third-speed shift fork on the second and third-speed synchronizer.
12. Place a detent plug spring and a plug in the case (Fig. 20). Place the second and third-speed synchronizer in the second-speed position (toward rear of transmission). Align the fork and install the second and third-speed shift rail. It will be necessary to depress the detent plug to enter the rail in the bore. Move the rail inward until the detent plug engages the forward notch (second-speed position).
13. Secure the fork to the shaft with the set screw. Move the synchronizer to the neutral position.
14. Install the interlock plug in the case. If the second and third-speed shift rail is in the neutral position, the top of the interlock will be slightly lower than the surface of the first and reverse shift rail bore.
15. Move the first and reverse synchronizer forward to the first-speed position. Place the first and reverse shift fork in the groove of the first and reverse synchronizer.

Rotate the fork into position and install the first and reverse shift rail. Move the rail inward until the center notch (neutral) is aligned with the detent bore. Secure the fork to the shaft with the set screw.

16. Install a new shift rail expansion plug in the front of the case.
17. Hold the input shaft and blocking ring in position. Then move the output shaft forward to seat the pilot in the roller bearings of the input gear.
18. Tap the input gear bearing into place in the case while holding the output shaft to prevent the roller bearings from dropping. Install the front bearing retainer and new gasket making sure that the oil return slot is at the bottom of the case. Install and torque the attaching screws to specification.
19. Install the large snap ring on the rear bearing. Place the bearing on the output shaft with the snap ring end toward the rear of the shaft. Press the bearing into place with the tool shown in Fig. 20. Secure the bearing to the shaft with a snap ring.
20. Hold the speedometer drive gear lock ball in the detent and slide the speedometer drive gear into place. Secure the gear with a snap ring.
21. Place the transmission in the vertical position. Working through the drain hole in the bottom of the case, align the bore of the countershaft gear and the thrust washers with the bore of the case with a screwdriver.
22. Working from the rear of the case, push the dummy shaft out of the countershaft gear with the countershaft. Before the countershaft is completely inserted in the bore, make sure that the hole that accommodates the roll pin is aligned with the hole in the case. Drive the shaft into place and install the roll pin.
23. Coat a new extension housing gasket with sealer and position it on the case.
24. Install lock washers on the five attaching screws. Dip the threads of the capscrews in the sealer. Secure the housing to the case and torque the capscrews to specification.
25. Place the transmission in gear. Pour lubricant over the entire gear train while rotating the input or output shaft.
26. Install the remaining detent plug in the case. Install the long spring (which is retained by the case) to secure the detent plug. Install a new T.R.S. switch, if required. Torque the switch to specifications.
27. Coat a new cover gasket (Fig. 15) with sealer. Secure the cover with capscrews. Attach the T.R.S. switch wire clip with the left front capscrew. Torque the screws to specification.
28. Check the operation of the transmission in all of the gear positions.

SUB-ASSEMBLIES

SHIFT LEVERS AND SEALS

1. Remove the nut, lock washer, and flat washer that secure each shift lever (Fig. 25) to the lever and shaft in the transmission case. Lift the levers off the shaft. Slide each lever and shaft out of the case. Discard the O-ring from each shaft.
2. Lubricate the new seals with transmission lubricant and install them on the shafts.
3. Install the lever and shafts in the case.
4. Position a shift lever on each shaft and secure them with a flat washer, lock washer, and nut.

INPUT SHAFT BEARING

1. Remove the snap ring securing the input shaft bearing (Fig. 26), and press the input shaft out of the bearing.
2. Press the input shaft bearing onto the input shaft with the tool shown in Fig. 27 and install the snap ring on the shaft.

SYNCHRONIZERS

1. Punch or etch alignment marks on the hub of the synchronizer before disassembly. Push the synchronizer hub from each synchronizer sleeve.
2. Separate the inserts and insert springs from the hubs. Do not mix the parts from the second and third-speed synchronizer with the first and reverse synchronizer (Figs. 28 and 29).

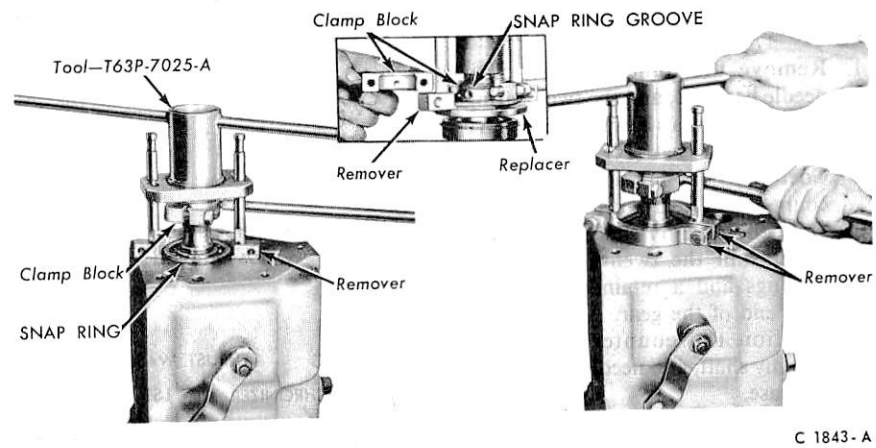

FIG. 18 Removing Output Shaft Bearing

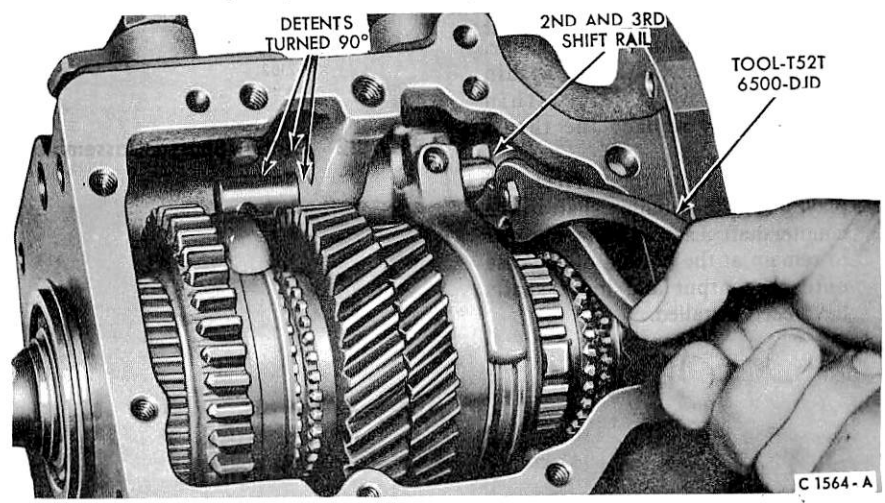

FIG. 19 Rotating Second and third-Speed Shift Rail

3. Install the insert spring in the hub of the first and reverse synchronizer. Make sure that the spring covers all the insert grooves. Start the hub on the sleeve, making sure that the alignment marks are properly indexed. Position the three inserts in the hub, making sure that the small end is on the inside of the hub. Slide the sleeve and reverse gear onto the hub.
4. Install one insert spring (Fig. 30) into a groove of the second and third-speed synchronizer hub, making sure that all three insert slots are fully covered. With the alignment marks on the hub and sleeve aligned, start the hub into the sleeve. Place the three inserts on top of the retaining spring and push the assembly together. Install the remaining insert spring so that the spring ends cover the same slot as does the other spring. Do not stagger the springs. Place a synchronizer blocking ring on each end of the synchronizer sleeve.

COUNTERSHAFT GEAR BEARINGS

1. Remove the dummy shaft, fifty needle bearings, and the two bearing retainer washers from the countershaft gear (Fig. 31).
2. Coat the bore in each end of the countershaft gear with grease.
3. Hold the dummy shaft in the gear and install the twenty-five needle bearings and a retainer washer in each end of the gear.
4. Position the countershaft gear, dummy shaft, and needle bearings in the case.
5. Place the case in a vertical position. Align the gear bore and the thrust washers with the bores in the case and install the countershaft.
6. Place the case in a horizontal position and check the countershaft gear end play with a feeler gauge. The end play should be within specification. If not within specification, replace the thrust washers.
7. After establishing the correct end play, install the dummy shaft in the countershaft gear and allow the gear to remain at the bottom of the case until the output and input shafts have been installed.

DESCRIPTION

TRANSMISSION

This three-speed heavy duty transmission incorporates both helical cut and spur gears (Fig. 1). A blocking-ring type synchronizer is used to shift the second and third-speed gears. Spur tooth gears are used for the low and reverse gears. Helical cut gears are used for second and third-speed gears. Ball bearings support the input shaft and the output shaft. Roller bearings, located in the input shaft, support the front end of the output shaft. The cluster gear is also mounted on roller bearings. All gears and bearings are splash lubricated by oil in the transmission case. The housing assembly, mounted on the top of the case, incorporates the remote control shift mechanism (Fig. 2).

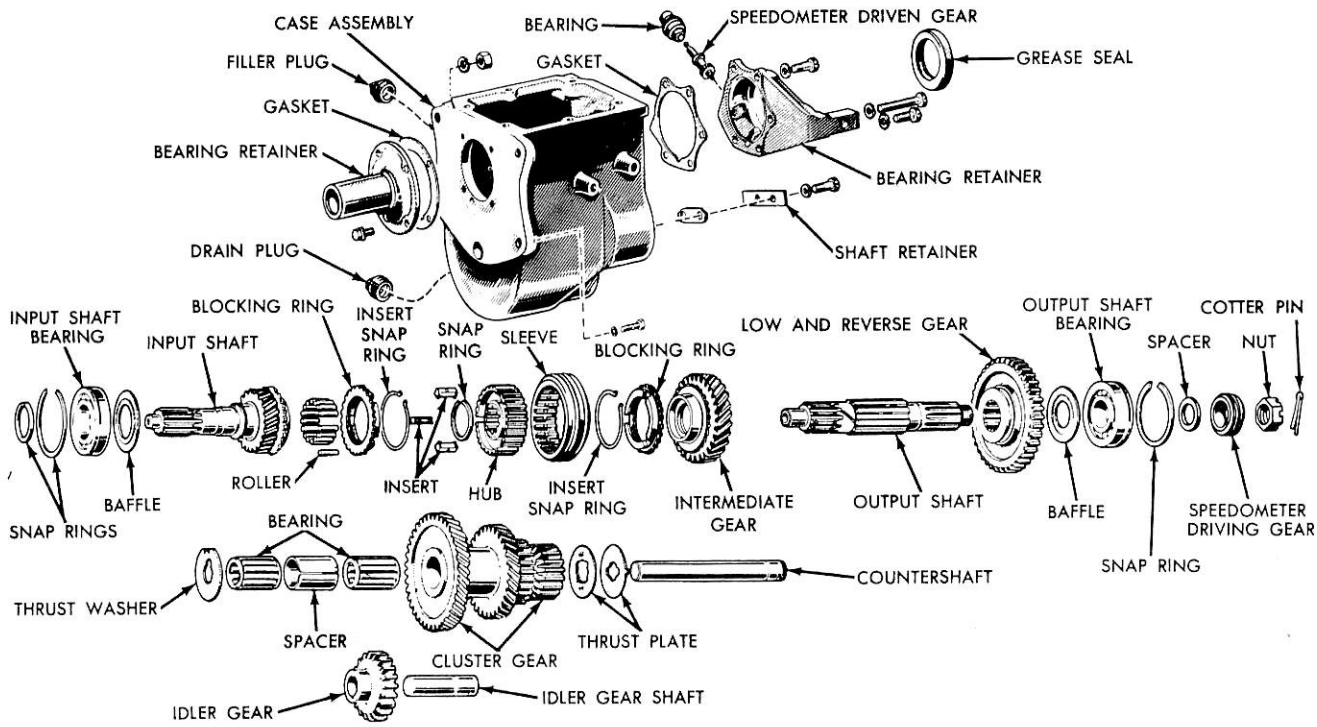

FIG. 1 Model T-87G Three-Speed Heavy Duty Transmission

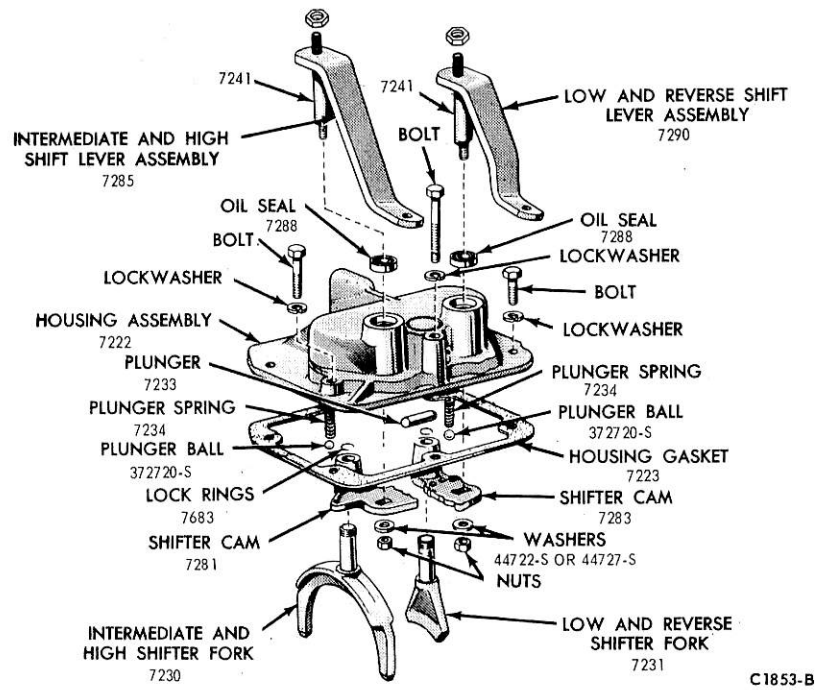

FIG. 2 Model T-87G Gear Shift Housing

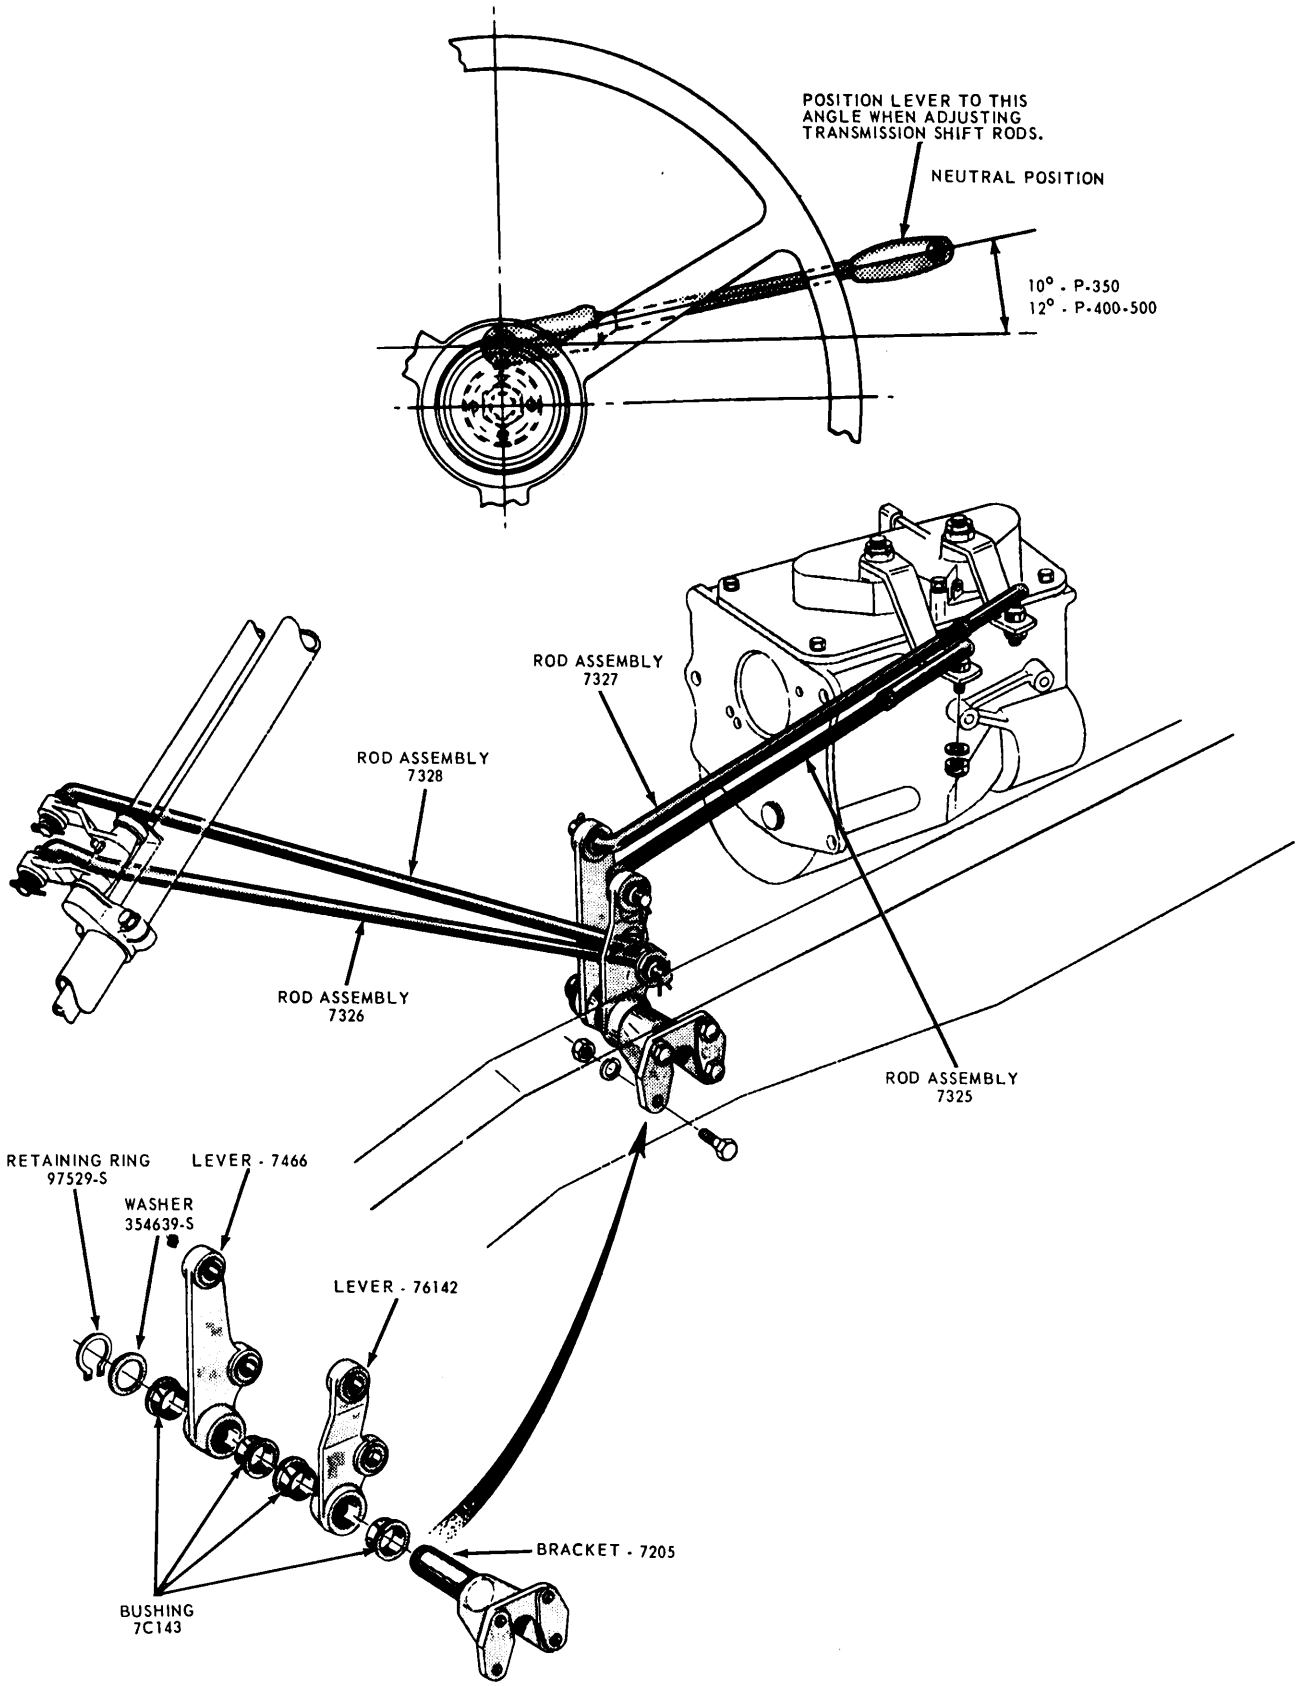

FIG. 3 Gear Shift Linkage Adjustment—P-Series

ADJUSTMENTS

GEAR SHIFT LINKAGE

1. Check the operation of the gear shift linkage for smooth cross-over operation.
2. To adjust the gear shift linkage, move the selector lever to the neutral position. Refer to Fig. 3 for correct position of the lever and neutral specifications.
3. If the selector lever position must be changed, disconnect the adjustable rods at the transmission.
4. Position the sleeves on the rods so that the ends enter the levers freely. Connect the rods.
5. Move the gear shift lever through all shift pattern positions as a final check for smooth operation.

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Raise the vehicle and position safety stands. Drain and discard the transmission lubricant. Position a transmission jack under the transmission, and disconnect the speedometer cable.
2. Disconnect the gear shift linkage at the transmission.
3. If the vehicle is equipped with a band-type parking brake, disconnect the brake cable clevis at the cam. Remove the brake conduit clamp.
4. Remove the front U-joint flange attaching bolts. Remove the bolts that attach the coupling shaft center support to the crossmember and wire the coupling shaft and drive shaft to one side.
5. Remove the transmission attaching bolts, and install guide studs.
6. Move the transmission to the rear until the input shaft clears the clutch housing, then lower the transmission.

Installation

Before installing the transmission, apply a light film of lubricant (C1AZ-19590-B) to the clutch disc splines, release bearing inner hub surfaces, release lever fulcrum and fork, and the transmission front bearing retainer. Care must be exercised to avoid excessive grease contaminating the clutch disc.

1. Place the transmission on a jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork.
2. Install guide studs in the two lower tapped holes in the clutch housing and slide the transmission forward on the guide studs until it contacts the clutch housing. It may be necessary to place the transmission in gear and rotate the output shaft to engage the clutch splines with the input shaft. Install the two upper attaching bolts and nuts, and torque them to specifications. Remove the guide pins and install the lower bolts.
3. Connect the speedometer cable and driven gear and parking brake clevis. Install the brake cable conduit clamp, and shift linkage.
4. Install the bolts attaching the coupling shaft center support to the crossmember. Torque the bolts to specifications.
5. Install the bolts attaching the front U-joint flange to the transmission output shaft flange. Torque the bolts and nuts to specifications.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Mount the transmission in an overhaul stand.
2. Remove the gear shift housing and the gasket from the case.
3. Lock the output shaft by shifting the transmission into two gears. Remove the output shaft nut and washer, and the parking brake anchor and bracket.
4. Remove the parking brake band assembly, the brake drum, and the flange as an assembly.
5. Remove the output shaft bearing retainer, speedometer driving gear, and spacer.
6. Remove the countershaft and reverse idler shaft retainer (Fig. 1).
7. Drive the countershaft out through the rear of the case.
8. Pull the output shaft bearing with the tool shown in Fig. 4.
9. Remove the input shaft bearing retainer and gasket. Tap the input shaft and bearing as far forward as they will go.
10. Remove the output shaft assembly from the case. Slide the low and reverse sliding gear off the end of the output shaft (Fig. 1). Remove the snap ring and then remove the synchronizer assembly and intermediate gear from the output shaft.
11. Remove the snap ring from the input shaft bearing outer race. Tap the input shaft bearing outer race toward the rear until it clears the case. Remove the shaft and bearing.

If the input shaft bearing is to be replaced, press the old bearing off. When the new bearing is pressed on, make sure the baffle at the rear of the bearing does not rub the bearing outer race. Install the thickest bearing retaining snap ring that will fit. Snap rings are available in the following

thicknesses: 0.094, 0.097, 0.100, 0.103 inch.

12. Pull the reverse idler shaft with Tool T50T-7140-B.
13. Remove the reverse idler gear and the cluster gear from the case.
14. If repair is necessary on the gear shift housing, remove the nuts and flat washers from the inner ends of the shift lever assemblies (Fig. 2). Tap the inner ends of the levers until the shifter cams are forced off the shafts.
15. Raise the cams slowly and remove the shaft lock plunger springs and balls. Slide the plunger out of the bore in the housing. Remove the snap rings which retain the shifter forks in the cams, and remove the forks. Remove the shift lever oil seals from the housing.
16. Clean and inspect the parts as outlined in Part 16-10.

Assembly

1. Position the reverse idler gear in the transmission case, and position the reverse idler shaft.
2. Drive the reverse idler shaft into the case until the inner edge of the retainer notch in the shaft is 1/16 inch from the rear face of the case.
3. Install the spacer and the two countershaft bearings in the cluster gear. Coat the thrust washer and the thrust plates with enough grease to hold them in position on the ends of the cluster gear.
4. Install the cluster gear front thrust washer, with the washer tip hooked into the groove on the inside of the case. Position the cluster gear assembly in the case, with the larger gear toward the front. Temporarily install the countershaft, and check the cluster gear end play. Change the thrust washers as required to obtain 0.006 to 0.020 inch end play. Remove the countershaft.
5. Slide the intermediate gear onto the front end of the output shaft. Coat the synchronizer blocking ring with grease, and install the ring on the intermediate gear. Install the synchronizer assembly on the shaft. The cutouts on the synchronizer ring must mate with the inserts on the hub. Install the snap ring on the shaft.
6. With a feeler gauge, check the end play between the intermediate gear and the shaft spline shoulder (Fig. 5). If the end play exceeds 0.020 inch inspect the gear and the shaft for wear. Replace any worn parts. Install the low and reverse sliding gear on the rear end of the output shaft.
7. Position the input shaft in the case, and tap it as far forward as it will go.
8. Position the output shaft assembly in the case.
9. Place a short 2 x 4 block between the input and output shafts (Fig. 6).
10. Slide the output shaft bearing baffle and bearing onto the output shaft. The baffle is not flat. It must be installed so that it does not rub the bearing outer race. Drive the bearing onto the shaft with the tool shown in Fig. 6.
11. Remove the 2 x 4 block, and place the output shaft pilot roller bearings in the input shaft. Retain them with grease. Place the front blocking ring on the synchronizer.
12. Start the input shaft bearing into the case so that the input shaft is in proper alignment.
13. With the tool shown in Fig. 6, drive the output shaft bearing into the case.
14. Tap the input shaft and bearing into place. Install the input shaft bearing retainer without a gasket, and tighten the bolts to bottom the retainer on the bearing outer race snap ring. With a feeler gauge, check the clearance between the bearing retainer gasket surface and the case.

Select a gasket or gaskets which will seal the oil between the bearing retainer and case, and at the same time prevent any end play between the bearing outer race snap ring and the retainer. Install the bearing retainer. Gaskets are available in the following thickness: 0.008-0.012, 0.0135-0.0165, 0.018-0.022, and 0.0225-0.0275 inch.

15. Raise the cluster gear assembly until the bore in the gear is aligned with the countershaft holes in the transmission case. The thrust washer and thrust plates must be properly aligned. Insert the end of the countershaft in the hole in the rear end of the case.

Drive the countershaft forward until the edge of the notch in the shaft is 1/16 inch from the face of the transmission case.

The countershaft notch must be aligned with the notch in the reverse idler shaft.

16. Install the countershaft and reverse idler shaft retainer and gasket. Do not tighten the bolts. Drive both shafts toward the front (1/16 inch) so that the retainer is tight against its gasket. Torque the shaft retainer bolts to specification.
17. Install the speedometer gear and spacer. After installing a new rear oil seal, install the output shaft bearing retainer and gasket, apply grease to the seal lips and cavity and install the drive flange.
18. Shift the transmission into two gears to lock the output shaft. Install the output shaft nut and washer, and torque to specification.
19. If the gear shift housing cover was disassembled, press new oil seals into the shift lever bores in the gear shift housing. Place the shifter forks in the cams, and install the snap rings which retain the forks in the cams (Fig. 2).
20. Install the shaft lock plunger in the bore in the housing, and place the springs and balls in the holes provided for them. Install the shift lever assemblies in the housing.
21. Position the shifter cams on the inner ends of the lever shafts, and drive the cams onto the shafts until they are seated against the shaft shoulders. Install the flat washers and nuts on the inner ends of the shift lever assemblies, and tighten the nuts securely. Shift the forks and cams into the neutral position.
22. Shift the transmission into neutral. Place a new gasket on the gear shift housing, and install the housing on the case.
23. Check transmission operation in all gears.
24. Fill the transmission with the correct amount of the proper lubricant (SAE 50 motor oil). This should be done through the speedometer cable attachment hole.

DESCRIPTION

TRANSMISSION

The four-speed Model T-18 synchro-silent transmission is equipped with a center, floor-mounted gear shift lever.

The first and reverse gears are spur gears and the second, third, and fourth-speed gears are helical.

The input shaft is supported by a ball bearing (Fig. 1), which is pressed onto the shaft and into the transmission case.

The front end of the output shaft is supported by a pilot bearing installed in the input shaft. The rear end of the output shaft is supported by a ball bearing which is pressed onto the shaft and into the transmission case. The bearing and shaft are retained in the case by a snap ring. Rear oil seal, speedometer gear and rear bushing are contained in the extension housing bolted to the rear of the case.

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Disconnect the back-up light switch located at the rear of the gearshift housing cover.
2. Remove the rubber boot, floor mat, and the body floor pan cover, and remove the transmission shift lever. Remove the weather pad.
3. Raise the truck and position safety stands. Position a transmission jack under the transmission, and disconnect the speedometer cable.
4. Disconnect the drive shaft from the transmission and wire to one side.
5. Remove the transmission rear support.
6. Remove the transmission attaching bolts.
7. Move the transmission to the rear until the input shaft clears the clutch housing, and lower the transmission.

Installation

Before installing the transmission, apply a light film of lubricant (C1AZ-19590-B) to the clutch release bearing inner hub surfaces, release lever fulcrum and fork, and the transmission front bearing retainer. Care must be exercised to avoid excessive grease contaminating the clutch disc.

1. Place the transmission on a transmission jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork.
2. Install guide studs in the clutch housing and slide the transmission forward on the guide studs until it is in position on the clutch housing. Install the attaching bolts and nuts, and torque them to specifications. Remove the guide studs and install the two lower attaching bolts.
3. Connect the speedometer cable and driven gear.
4. Install the bolts attaching the front U-joint to the transmission output shaft flange. Torque the bolts and nuts to specifications. Install the transmission rear support.
5. Connect the back-up light switch.
6. Install the shift lever and lubricate the spherical ball seat with lubricant M1C75B (C1AZ-19590-B).
7. Install the weather pad. Install the floor pan cover, floor mat and boot.

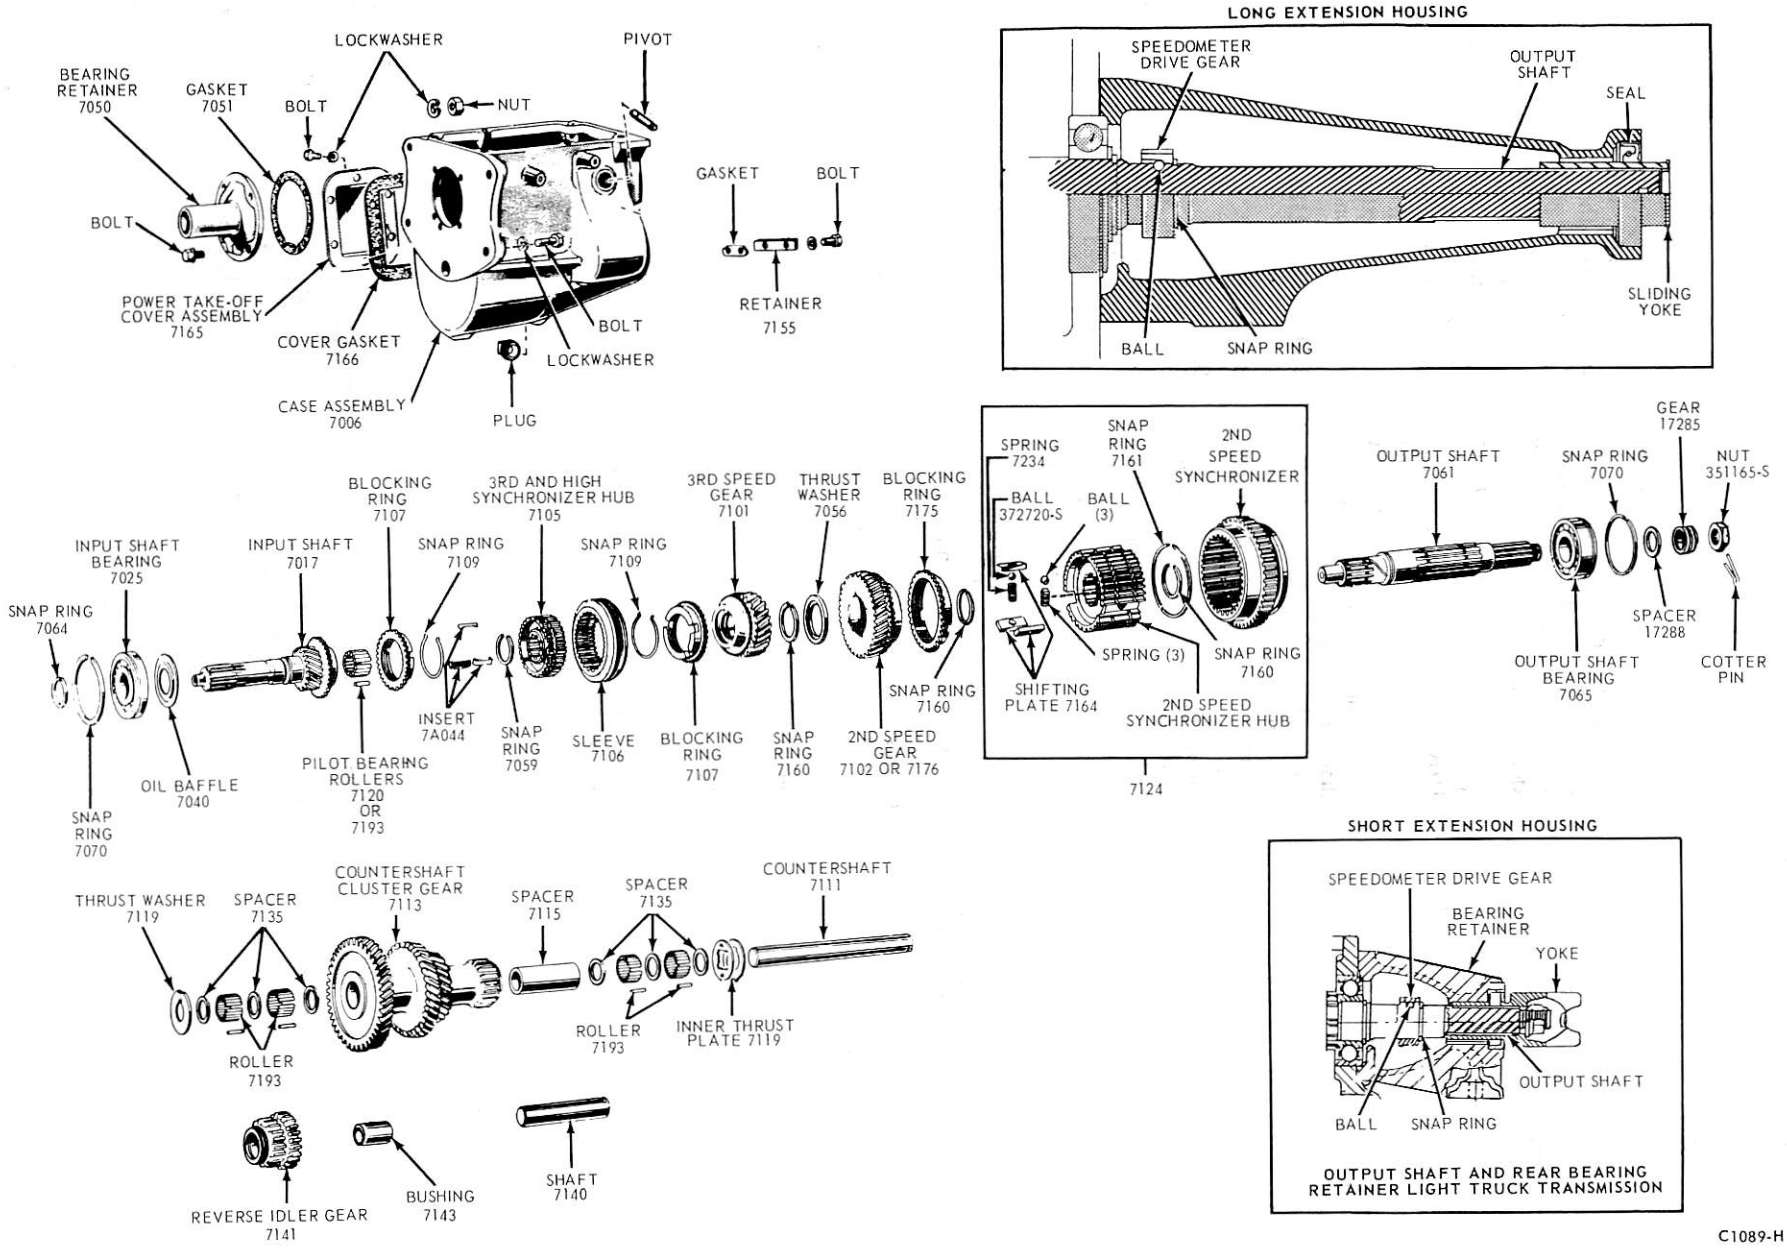

FIG. 1 Warner T-18 Four Speed Transmission

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. After draining the transmission and removing the gear shift housing lock the transmission in two gears and remove the U-joint flange and oil seal.
2. Remove the speedometer driven gear and bearing assembly.
3. Remove the output shaft bearing retainer (or extension) and the speedometer drive gear and spacer.
4. Remove the output shaft bearing snap ring, and remove the bearing using tools OTC951 and 927.
5. Remove the countershaft and idler shaft retainer and the power takeoff cover.
6. After removing the input shaft bearing retainer, remove the snap rings from the bearing and the shaft.
7. Remove the input shaft bearing. Remove the oil baffle.
8. Use the tool shown in Fig. 2 to drive out the countershaft (from the front). **Keep the dummy shaft in contact with the countershaft to avoid dropping any rollers.**
9. After removing the input shaft and the synchronizer blocking ring, pull the idler shaft, using the tool shown in Fig. 3.
10. Remove the reverse gear shifter arm. Then remove the output shaft assembly, the idler gear, and the countershaft gear. When removing the countershaft gear, do not lose any of the rollers.

Assembly

1. Coat all parts, especially the bearings, with the specified transmission lubricant to prevent scoring when the transmission is first operated.

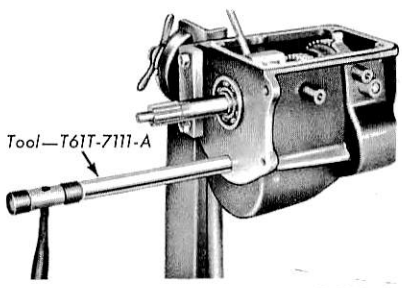

FIG. 2 Removing Countershaft

2. Position the countershaft gear assembly in the case. **Do not lose any rollers.**
3. Position the idler gear assembly in the case, and install the idler shaft. **Position the slot in the rear of the shaft so that it can engage the retainer.** Install the reverse shifter arm.
4. Drive out the countershaft gear dummy shaft by installing the countershaft from the rear. **Position the slot in the rear of the shaft so that it can engage the retainer.**
5. Check the countershaft gear end play, and use thrust washers as required to get 0.006 to 0.020 inch end play.
6. Install the countershaft and idler shaft retainer.
7. Position the input shaft pilot rollers and the oil baffle, placing the baffle so that it will not rub the bearing race. Position the input shaft in the case and install the blocking ring.
8. Install the output shaft assembly in the case, and position the tool shown in Fig. 4 to prevent jamming the blocking ring when the input shaft bearing is installed.
9. Drive the input shaft bearing onto the shaft, using the tool shown in Fig. 5. Install the thickest select-fit snap ring that will fit on the bearing. This snap ring is available in the following thicknesses: 0.117-0.119, 0.120-1.122, 0.123-0.025, and 0.127-0.129 inch. Install the input shaft snap ring.
10. Install the output shaft bearing, using the tool shown in Fig. 5. If the output shaft bearing is to be replaced, be sure it is a maximum load rated bearing.
11. Install the input shaft bearing retainer **without a gasket,** and tighten the bolts only enough to bottom the retainer on the bearing snap ring.

Measure the clearance between the retainer and the case, and select a gasket (or gaskets) that will seal in the oil and at the same time prevent end play between the retainer and the snap ring. Gaskets are available in the following thicknesses: 0.008-0.011, 0.0135-0.0165, 0.018-0.022 and 0.0225-0.0275 inch. Torque the bolts to specifications.

12. Position the speedometer drive gear and spacer, if required, and install a new output shaft bearing retainer gasket.
13. Install the output shaft bearing retainer (or extension). Torque the bolts to specification. If required, install safety wire.
14. Lubricate the extension housing bushing and seal and U-joint flange with ball joint grease.
15. Install the U-joint flange. Lock the transmission in two gears and torque the nut to specification.
16. Fill the transmission to the proper level (through the speedometer cable hole in the extension housing) with the recommended lubricant.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the third and high speed synchronizer hub snap ring from the output shaft, and slide the third and high-speed synchronizer assembly and the third-speed gear off the shaft.
2. Remove the synchronizer sleeve and the inserts from the hub. Before removing the two snap rings from the ends of the hub, check the end play of the second-speed gear. There should be 0.005 to 0.024 inch of end play.
3. Remove the second-speed synchronizer snap ring. Slide the second-speed synchronizer gear off the hub.

Be careful not to lose any of the balls, springs or plates, nor the anti-rattle spring and ball. Pull the hub synchronizer off the shaft, and remove the second-speed synchronizer from the second-speed gear.

4. Remove the snap ring from the rear of the second-speed gear, and remove the gear, and thrust washer from the output shaft.

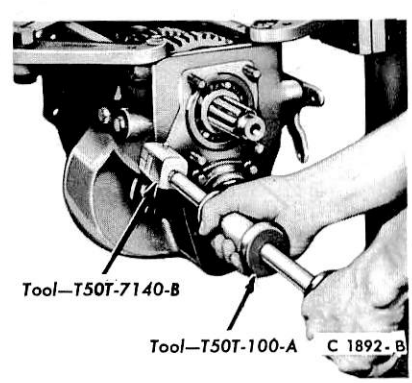

FIG. 3 Removing Reverse Idler Shaft

Assembly

1. Install the second-speed gear thrust washer and snap ring on the output shaft. Hold the shaft in a vertical position, and slide the second-speed gear onto the shaft.
2. Install the snap ring on the output shaft at the rear of the second-speed gear. Position the blocking ring on the second-speed gear. **Do not invert the shaft because the bearing rollers will slide out of the gear.**
3. Press the second-speed synchronizer hub onto the shaft, and install the snap ring.
4. Position the output shaft vertically in a soft-jawed vise. Position the springs and plates in the second-speed synchronizer hub, and place the hub gear on the hub.
5. Hold the gear above the hub spring and ball holes, and position one ball at a time in the hub. Push the ball down into the hole, and slide the hub gear downward to hold the ball in the hub. Push the plate upward, and insert a small block to hold the plate in position, thereby holding the ball in the hub. Repeat these procedures to install the remaining balls in the hub. Install the anti-rattle spring and ball.
6. Remove the output shaft from the vise, and install the third-speed gear and synchronizer blocking ring on the shaft.
7. Install the snap rings at both ends of the third and high-speed synchronizer hub. Stagger the openings of the snap rings so that they are not in line with each other.
8. Place the inserts in the synchronizer sleeve, and position the sleeve on the hub.
9. Slide the synchronizer assembly onto the output shaft. The slots in the blocking ring must be in line with the synchronizer inserts. Install the snap ring at the front of the synchronizer assembly.

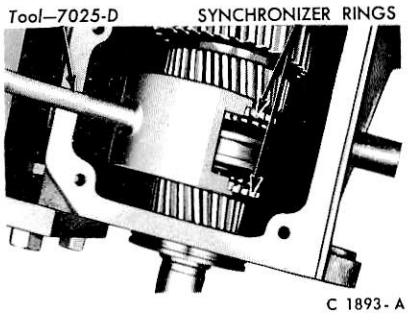

FIG. 4 Stop Yoke Tool

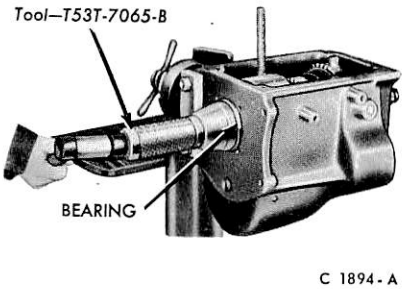

FIG. 5 Installing Input Shaft Bearing

COUNTERSHAFT GEAR

Disassembly

Remove the dummy shaft, pilot bearing rollers, bearing spacers, and the center spacer from the countershaft gear.

Assembly

1. Slide the long bearing spacer (Fig. 1) into the countershaft gear bore, and insert the dummy shaft in the spacer.
2. Hold the gear in a vertical position, and install one of the bearing spacers. Position the 22 pilot bearing rollers in the gear bore.
3. Place a spacer on top of the rollers, and install 22 more rollers and another spacer.
4. Hold a large thrust washer against the end of the countershaft gear to prevent the rollers from dropping out, and turn the assembly over. Install the rollers and spacers in the other end of the gear.

REVERSE IDLER GEAR

Disassembly

Replace the reverse idler gear if the gear or bushing is badly worn or if the

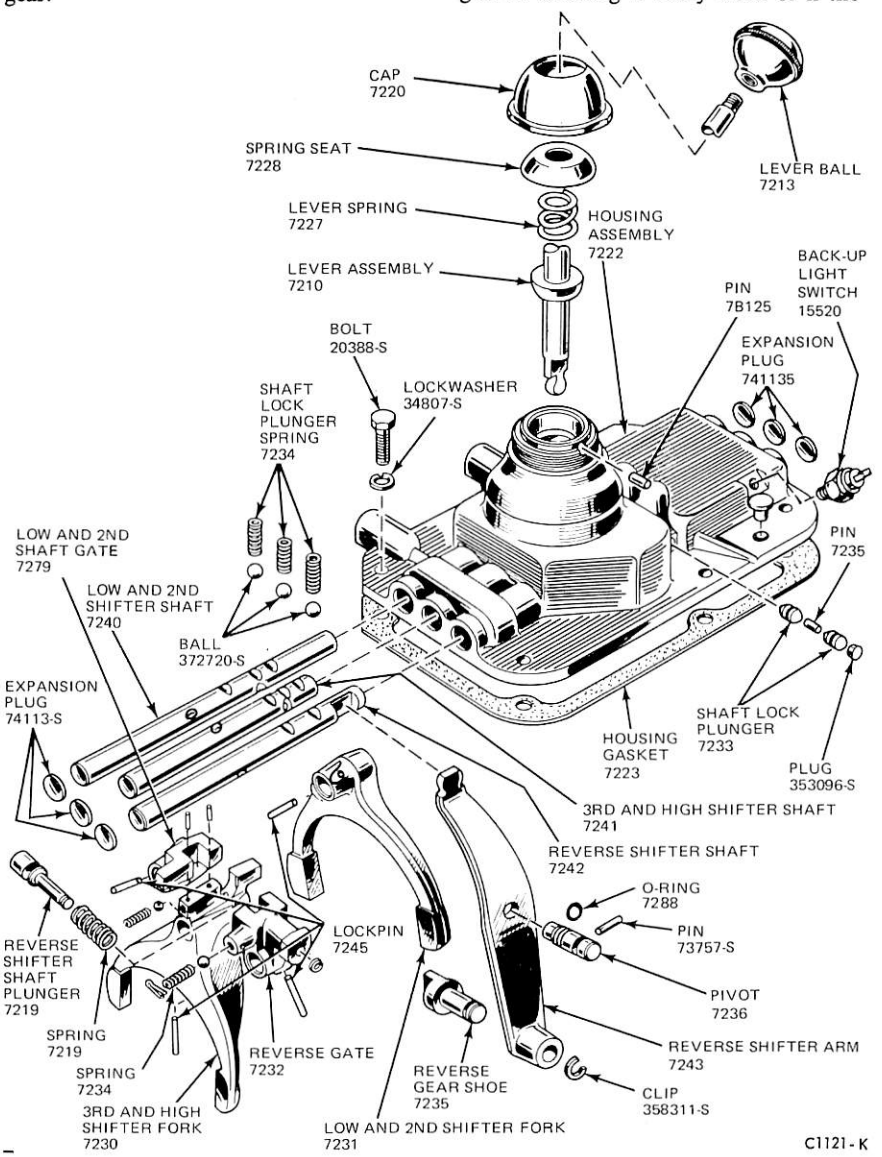

FIG. 6 Conventional Cab Gear Shift Housing

teeth are chipped or burred. Replace the reverse idler gear shaft if it is excessively worn or scored.

GEAR SHIFT HOUSING

Disassembly

1. Remove the back-up lamp switch from the housing (Fig. 6).
2. Remove the gear shift lever housing cap, and lift the lever out of the housing (Fig. 6). Be sure all shafts are in neutral before disassembly.
3. Remove the lock pin from the shifter forks and shifter shaft gates. Remove the expansion plugs from the forward end of the housing.
4. Tap the shifter shafts out of the housing while holding one hand over the holes in the housing to prevent loss of the springs and balls. Lift the two shaft lock plungers out of the housing.

Assembly

1. Place the spring on the reverse gear shifter shaft gate plunger, and install the spring and plunger in the reverse gate (Fig. 6). Press the plunger through the gate, and fasten it in place with the clip.
2. Place the spring and ball in the reverse gate poppet hole. Compress the spring and install the cotter pin.
3. Place the spring and ball in the reverse shifter shaft hole in the gear shift housing. Press down on the ball with a long, thin drift, and position the reverse shifter arm notch so that it does not slide over the ball. Insert the shaft part way into the housing.
4. Slide the reverse gate onto the shaft, and drive the shaft into the housing until the ball snaps into the groove of the shaft. Install the lock pin that fastens the gate to the shaft.
5. Insert the two interlocking plungers in the pockets between the shifter shaft holes. Place the spring and ball in the low and second shifter shaft hole. Press down on the ball, and insert the shifter shaft part way into the housing.
6. Slide the low and second shifter shaft gate onto the shaft, and install the low and second shifter fork on the shaft so that the offset of the fork is toward the rear of the housing. Push the shaft all the way into the housing until the ball snaps into the shaft groove. Install the roll pin that fastens the fork to the shaft.
7. Install the third and high shifter shaft in the same manner. Check the interlocking system. Install new expansion plugs in the ends of the shaft bores.
8. Install the back-up lamp switch in the housing. Torque the switch to specifications.

DESCRIPTION

TRANSMISSION

The four-speed fully synchronized T-19 transmission is equipped with a center, floor-mounted gear shift lever.

The reverse gear and the first, second, third and fourth-speed gears are helical.

The input shaft is supported by a ball bearing (Fig. 1) which is pressed onto the shaft and into the transmission case.

The front end of the output shaft is supported by a pilot bearing installed in the input shaft. The rear end of the output shaft is supported by a ball bearing which is pressed onto the shaft and into the transmission case. The bearing and shaft are retained in the case by a snap ring.

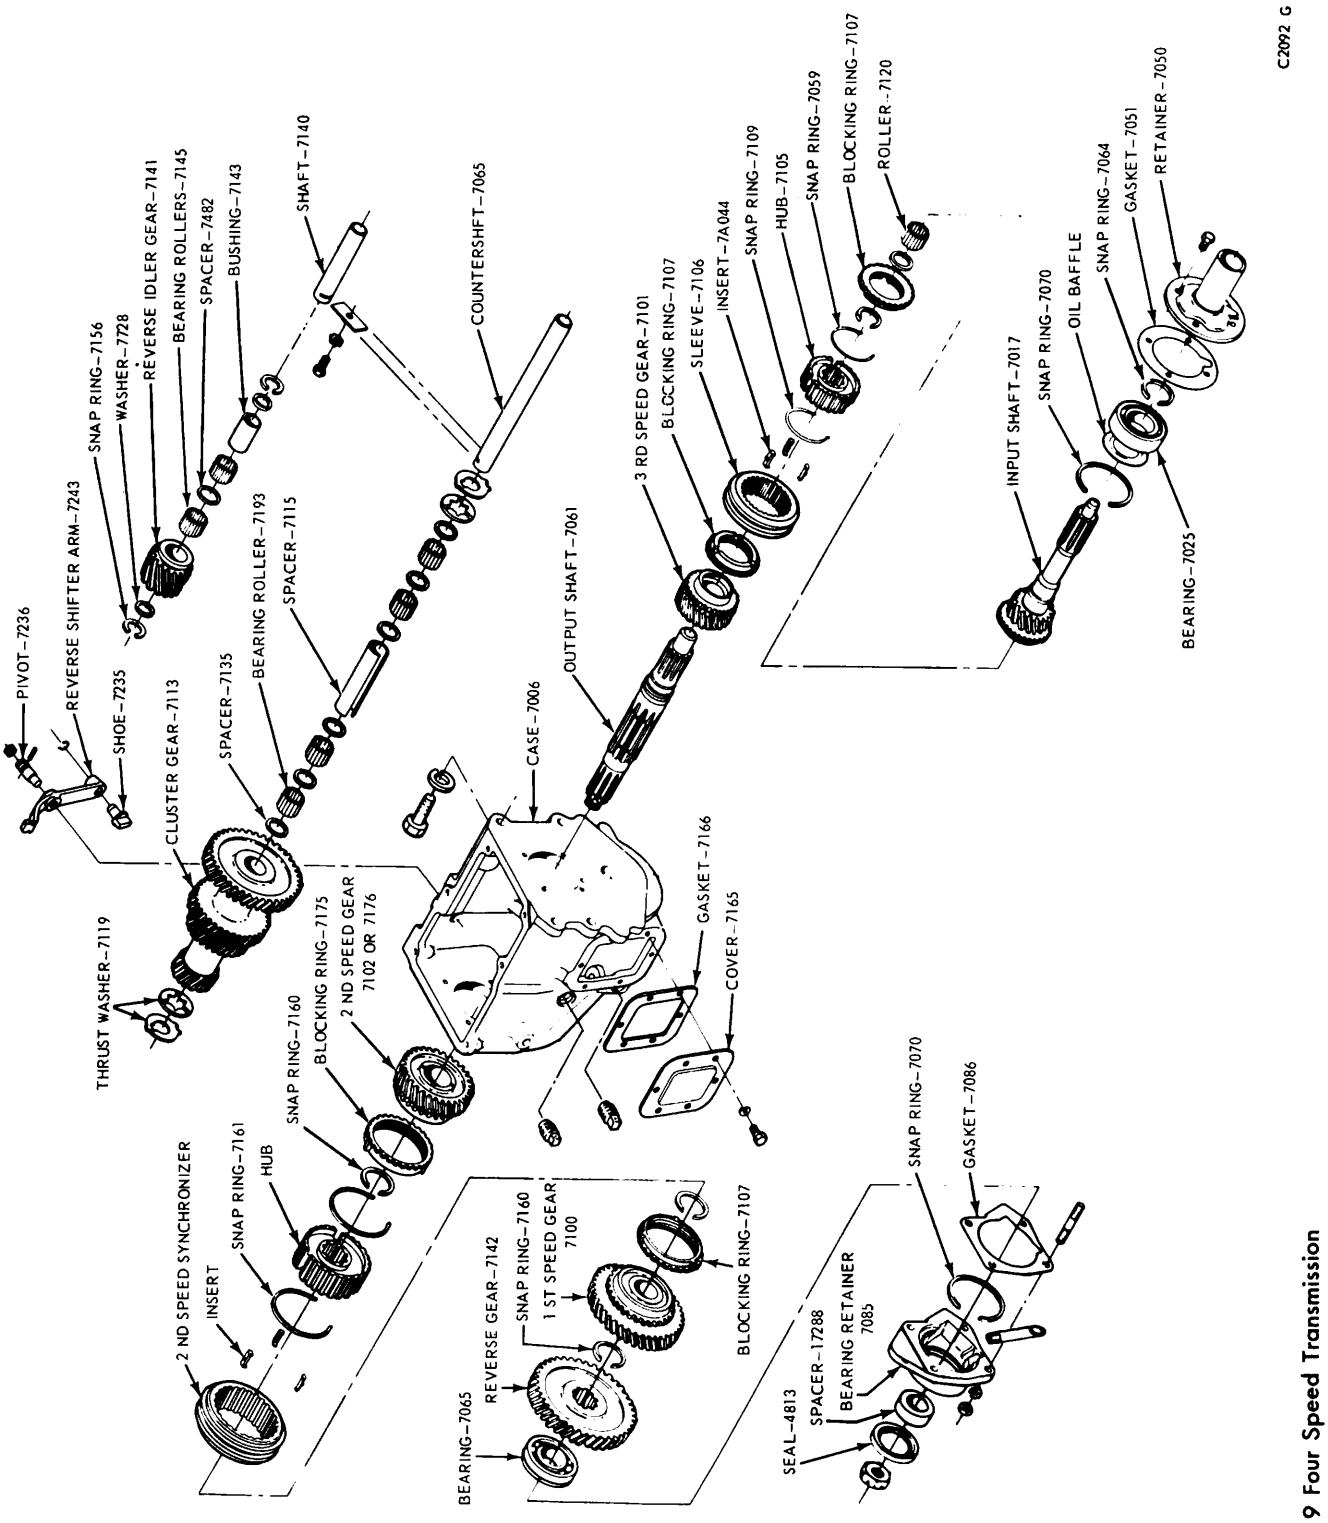

FIG. 1 Warner T-19 Four Speed Transmission

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Disconnect the back-up light switch located at the rear of the gear shift housing cover.
2. Remove the rubber boot, floor mat and body floor pan cover. Remove the transmission shift lever. Remove the weather pad and pad retainer.
3. Raise the truck and position safety stands. Position a transmission jack under the transmission and disconnect the speedometer cable.
4. If the truck is equipped with a band-type parking brake, disconnect the brake cable clevis at the cam. Remove the brake cable conduit clamp.
5. Remove the front U-joint flange attaching bolts. remove the bolts that attach the coupling shaft center support to the crossmember and wire the coupling shaft and drive shaft to one side.
6. Remove the transmission attaching bolts.
7. Move the transmission to the rear until the input shaft clears the clutch housing. Lower the transmission.

Installation

Before installing the transmission, apply a light film of lubricant (C1AZ-19590-B) to the release bearing inner hub surfaces, release lever fulcrum and fork, and the transmission front bearing retainer. Exercise care to avoid contaminating the clutch disc with excessive grease.

1. Place the transmission on a transmission jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork.
2. Install guide studs in the clutch housing and slide the transmission forward on the guide studs until it is in position on the clutch housing. Install the attaching bolts and nuts and torque them to specifications. Remove the guide studs and install the two lower attaching bolts.
3. Connect the speedometer cable and driven gear and parking brake clevis. Install the brake cable conduit clamp and shift linkage.
4. Install the bolts attaching the coupling shaft center support to the crossmember. Torque the bolts to specifications.
5. Install the bolts attaching the front U-joint flange to the transmission output shaft flange. Torque the bolts and nuts to specifications.
6. Connect the back-up light switch.
7. Install the shift lever and lubricate the spherical ball seat with ball joint lubricant (C1AZ-19590-B).
8. Install the weather pad and pad retainer. Install the floor pan cover, floor mat and boot.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. After draining the transmission and removing the gear shift housing and parking brake drum (or shoe assembly), lock the transmission in two gears and remove the U-joint flange and oil seal.
2. Disconnect the parking brake linkage, remove the brake shoe assembly (or drum) and remove the speedometer driven gear and bearing assembly.
3. Remove the output shaft bearing retainer (or extension) and the speedometer drive gear and spacer. Also remove the output shaft bearing retainer studs from the case.
4. Remove the output shaft bearing snap ring and remove the bearing using Tools OTC951 and 927.
5. Remove the countershaft and idler shaft retainer and the power takeoff cover.
6. After removing the input shaft bearing retainer, remove the snap rings from the bearing and the shaft.
7. Remove the input shaft bearing. Remove the oil baffle.
8. Remove the roll pin from the reverse gear shifter arm shaft and remove the shaft from the shifter. Lift the shifter out of the case.
9. Remove the output shaft and gear assemblies from the case.
10. Use the tool shown in Fig. 2 to drive out the countershaft (from the front). **Keep the dummy shaft in contact with the countershaft to avoid dropping the rollers.**
11. After removing the input shaft and the synchronizer blocking ring, pull the idler shaft, using the tool shown in Fig. 3.
12. Remove the idler gear and the countershaft gear. When removing the countershaft gear, do not lose any of the rollers.

Assembly

1. Coat all parts, especially the bearings, with the specified transmission lubricant to prevent scoring when the transmission is first operated.
2. Position the countershaft gear assembly in the case. **Do not lose any rollers.**
3. Position the idler gear assembly in the case and install the idler shaft. **Position the slot in the rear of the shaft so that it can engage the retainer.** Install the reverse shifter arm.
4. Drive out the countershaft gear dummy shaft by installing the countershaft from the rear. **Position**

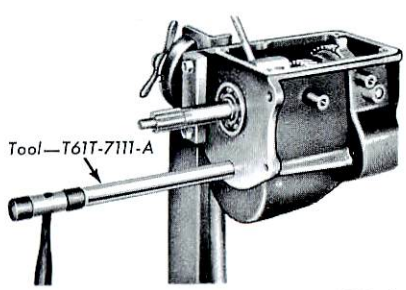

FIG. 2 Removing Countershaft

the slot in the rear of the shaft so that it can engage the retainer.

5. Check the countershaft gear end play. Use thrust washers as required to get 0.006 to 0.020 inch end play.
6. Install the countershaft and idler shaft retainer.
7. Position the input shaft pilot rollers and the oil baffle, placing the baffle so that it will not rub the bearing race. Position the input shaft in the case and install the blocking ring.
8. Install the output shaft assembly in the case.
9. Drive the input shaft bearing onto the shaft, using the tool shown in Fig. 4. Install the thickest select-fit snap ring that will fit on the bearing. This snap ring is available in the following thicknesses: 0.117-0.119, 0.120-0.122, 0.123-0.125, and 0.127-0.129 inch. Install the input shaft snap ring.
10. Install the output shaft bearing. If the output shaft bearing is to be replaced, be sure it is a maximum load rated bearing.
11. Install the input shaft bearing retainer (Fig. 1) **without a gasket and tighten the bolts only enough to bottom the retainer on the bearing snap ring.**

Measure the clearance between the retainer and the case and select a gasket (or gaskets) that will seal in the oil and at the same time prevent end play between the retainer and the snap ring. Gaskets are available in the following thickness: 0.008-0.011, 0.0135-0.0165, 0.018-0.022 and 0.0225-0.0275 inch. Torque the bolts to specification.

12. Position the speedometer drive gear and spacer, if required, and install a new output shaft bearing retainer gasket.
13. Install the output shaft bearing retainer (or extension). Torque the bolts to specification. If required, install safety wire.
14. Install the brake shoe (or drum) and torque the bolts to specification.
15. Lubricate the extension housing bushing and seal and U-joint flange with ball joint grease.
16. Install the U-joint flange. Lock the transmission in two gears and torque the nut to specification.
17. Fill the transmission to the proper level with the recommended lubricant (SAE 50 engine oil).

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the third and high-speed synchronizer hub snap ring from the output shaft and slide the third and high-speed synchronizer assembly and the third-speed gear off the shaft.
2. Place input shaft in an Arbor Press and press the reverse gear off the shaft.
3. Remove the first-speed snap ring and slide the first-speed gear off the output shaft.
4. Remove the first and second-speed synchronizer snap ring. Slide the second-speed synchronizer off the shaft.
5. Remove the snap ring from the rear of the second-speed gear. Remove the gear and thrust washer from the output shaft.

Assembly

1. Install the second-speed gear thrust washer and snap ring on the output shaft. Hold the shaft in a vertical position and slide the second-speed gear onto the shaft.
2. Install the snap ring on the output shaft at the rear of the second-speed gear. Position the blocking ring on the second-speed gear.
3. Press the first and second-speed synchronizer onto the shaft and install the snap ring.
4. Install the first-speed gear and snap ring on the shaft.
5. Mount the output shaft in a press and press the reverse gear on the shaft.
6. Remove the output shaft from the press. Install the third-speed gear and synchronizer blocking ring on the shaft.
7. Install the snap rings at both ends of the third and high-speed synchronizer hub. Stagger the openings of the snap rings so that they are not in line with each other.
8. Place the inserts in the synchronizer sleeve and position the sleeve on the hub.
9. Slide the synchronizer assembly onto the output shaft. The slots in the blocking ring must be in line with the synchronizer inserts. Install the snap ring at the front of the synchronizer assembly.

COUNTERSHAFT GEAR

Disassembly

Remove the dummy shaft, pilot bearing rollers, bearing spacers and center spacer from the countershaft gear.

Assembly

1. Slide the long bearing spacer (Fig. 1) into the countershaft gear bore and insert the dummy shaft in the spacer.
2. Hold the gear in a vertical position and install one of the bearing spacers. Position the 22 pilot bearing rollers in the gear bore.
3. Place a spacer on top of the rollers and install 22 more rollers and another spacer.
4. Hold a large thrust washer against the end of the countershaft gear to prevent the rollers from dropping out and turn the assembly over. Install the rollers and spacers in the other end of the gear.

REVERSE IDLER GEAR

Disassembly

Check the idler gear roller bearings for roughness by holding the bushing from turning while rotating the gear. The gear should then be installed on the shaft to check for roughness between the shaft and bushing. If the gear turns freely and smoothly, disassembly of the unit is not necessary. If any roughness is noticed, disassemble the unit as follows:

Remove the snap ring from one end of the gear. Remove the idler gear bearing rollers, thrust washers, bearing spacer and bushing from the gear.

Assembly

1. Install a snap ring (Fig. 1) in one end of the idler gear and set the gear on end, with the snap at the bottom.
2. Position a thrust washer in the gear on top of the snap ring. Install the bushing on top of the washer. Insert 37 bearing rollers between the bushing and the gear bore.
3. Install a spacer on top of the rollers and install 37 more rollers.
4. Place the remaining thrust washer on the rollers and install the other snap ring.

GEAR SHIFT HOUSING

Disassembly

1. Remove the gear shift lever housing cap and lift the lever out of the housing (Fig. 5). Be sure all shafts are in neutral before disassembly.

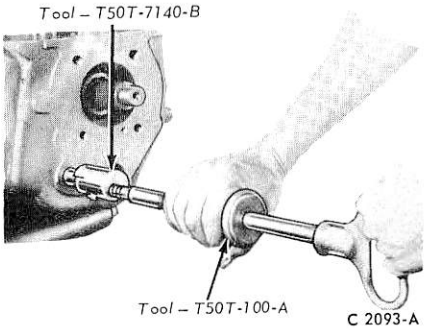

FIG. 3 Removing Reverse Idler Shaft

2. Remove the lock pin from the shifter forks and shifter shaft gates. Remove the expansion plugs from the forward end of the housing.
3. Tap the shifter shafts out of the housing while holding one hand over the holes in the housing to prevent loss of the springs and balls. Lift the two shaft lock plungers out of the housing.

Assembly

1. Place the spring on the reverse gear shifter shaft gate plunger. Install the spring and plunger in the reverse gate (Fig. 5). Press the plunger through the gate and fasten it in place with the clip.
2. Place the spring and ball in the reverse gate poppet hole. Compress the spring and install the cotter pin.
3. Place the spring and ball in the reverse shifter shaft hole in the gear shift housing. Press down on the ball with a long, thin drift and position the reverse shifter arm so that the notch does not slide over the ball. Insert the shaft part way into the housing.
4. Slide the reverse gate onto the shaft. Drive the shaft into the housing until the ball snaps into the groove of the shaft. Install the lock pin that fastens the gate to the shaft.
5. Insert the two interlocking plungers in the pockets between the shifter shaft holes. Place the spring and ball in the low and second shifter shaft hole. Press down on the ball and insert the shifter shaft part way into the housing.
6. Slide the low and second shifter shaft gate onto the shaft. Install the low and second shifter fork on the shaft so that the offset of the fork is toward the rear of the housing. Push the shaft all the way into the housing until the ball snaps into the shaft groove. Install the lock screw that fastens the fork to the shaft and install the lock wire.
7. Install the third and high shifter shaft in the same manner. Check the interlocking system. Install new expansion plugs in the ends of the shaft bores.

DESCRIPTION

TRANSMISSION

The four-speed Model 435 transmission (Fig. 1), is provided with a floor-mounted shift lever or with a floor-mounted remote shift lever.

The first and reverse gears are spur cut (Fig. 2). The second, third and fourth gears are helical cut, and are synchronized to permit easier shifting.

The input shaft is supported by a tapered roller bearing. The input shaft end play is controlled by the thickness of gaskets between the case and the front bearing retainer.

The front end of the output shaft is supported by a pilot bearing that is located in the input shaft. The rear end of the output shaft is supported by a ball bearing that is pressed onto the shaft. The bearing and shaft are held in the case by a snap ring and a bearing retainer. Retention of the output shaft in the case may vary, depending on application. Various extension housings are used, (Figs. 2 and 4) in order to fit several truck models.

The third and fourth-speed synchronizer is mounted on the forward end of the output shaft and is held in place by the gear end of the input shaft, and the third-speed gear. The third and second-speed gears are located between the shoulder and the third and fourth-speed synchronizer on the output shaft.

The second-speed synchronizer and the first-speed sliding gear is located toward the rear of the output shaft (Fig. 2). A spacer is provided to prevent the first-speed sliding gear from contacting the case.

The countershaft gear is supported by roller bearings installed at both ends of the gear. A roller type thrust bearing and a bearing race are provided at the rear end of the gear. A thrust washer is also provided at the front of the gear. Uncaged rollers are used in production, but caged roller assemblies are available for service.

The reverse idler gear is supported by roller bearings except in F-100-350 and P-Series installations, where a bronze bushing is used. Only the roller bearing type gear is supplied for service replacement, however. The bearings are installed between the gear and a sleeve on the reverse idler shaft. The sets of bearings are separated by a snap ring and bearing race retainer spacer. Snap rings, installed in the center of the reverse idler gear, hold the entire assembly in position.

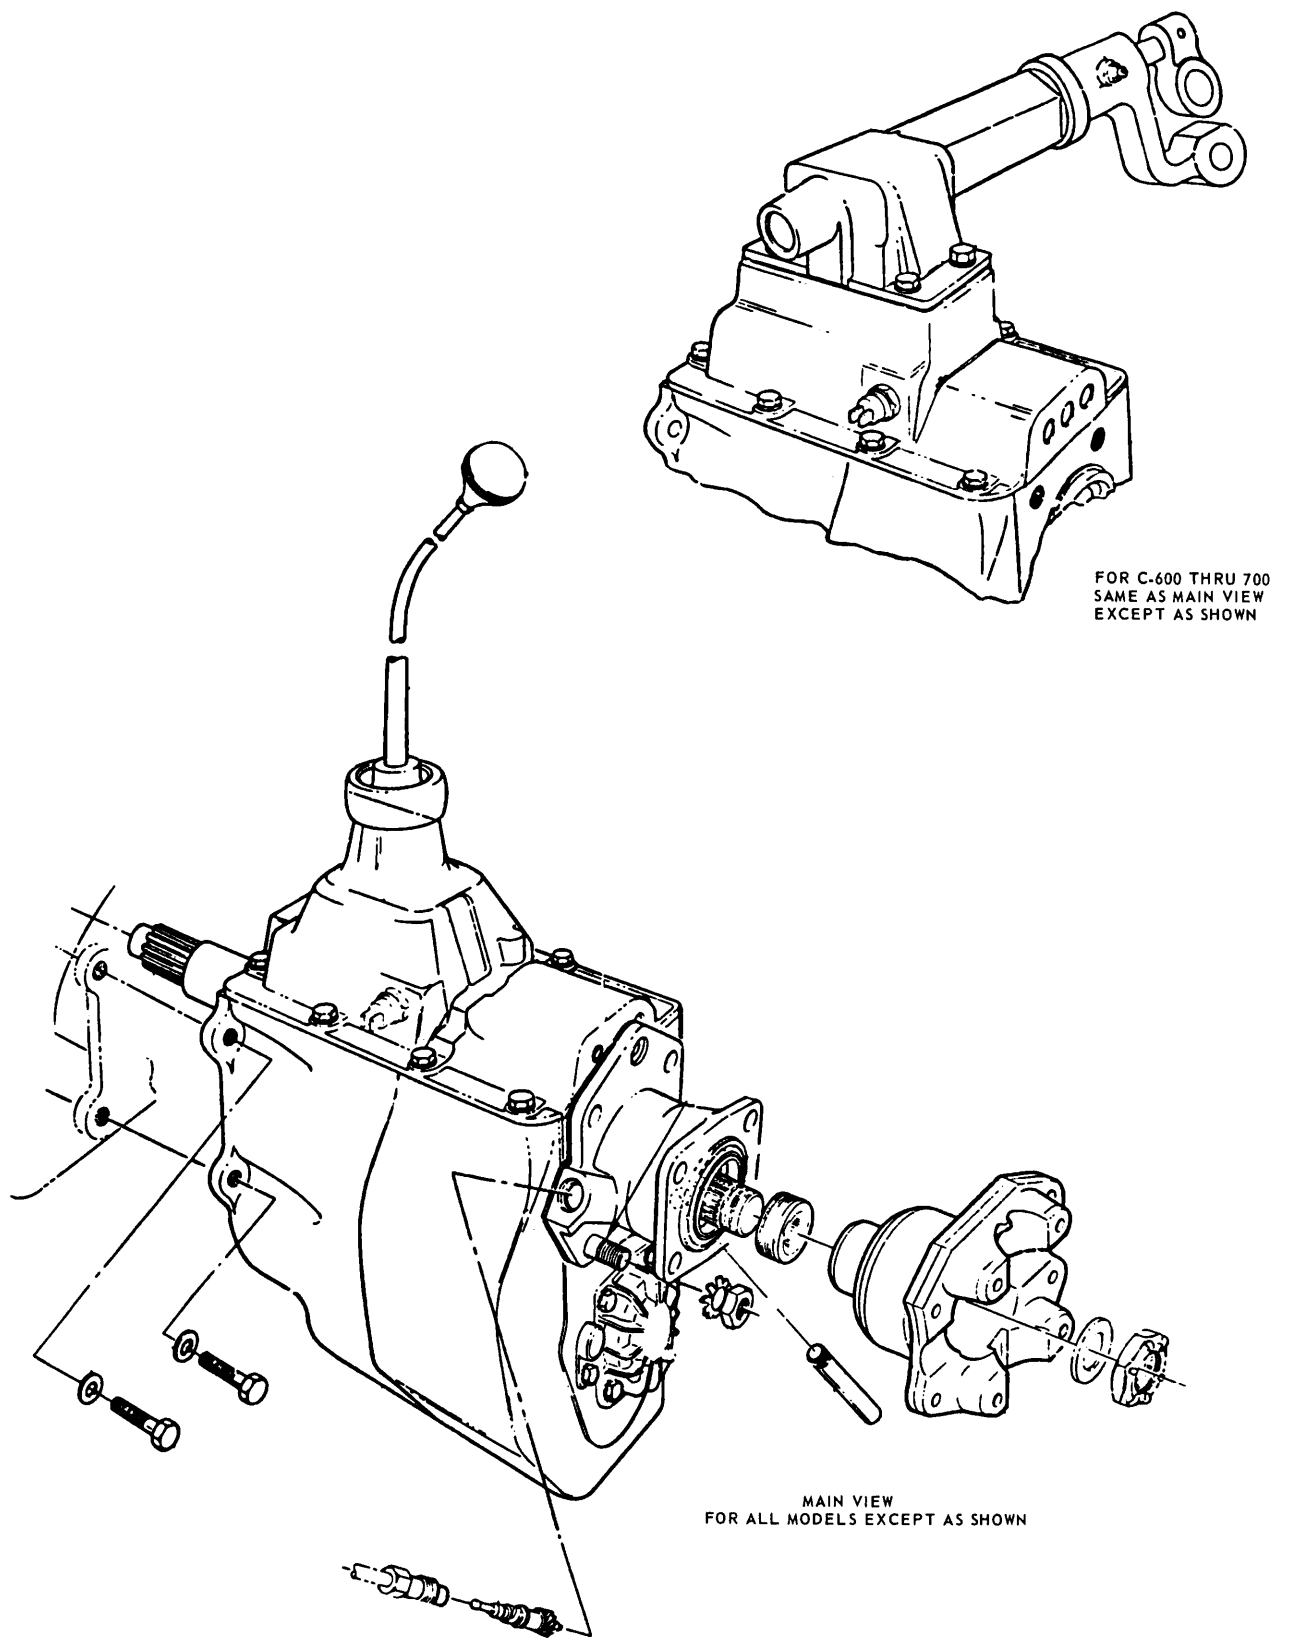

FIG. 1 New Process 435 Four-Speed Transmission

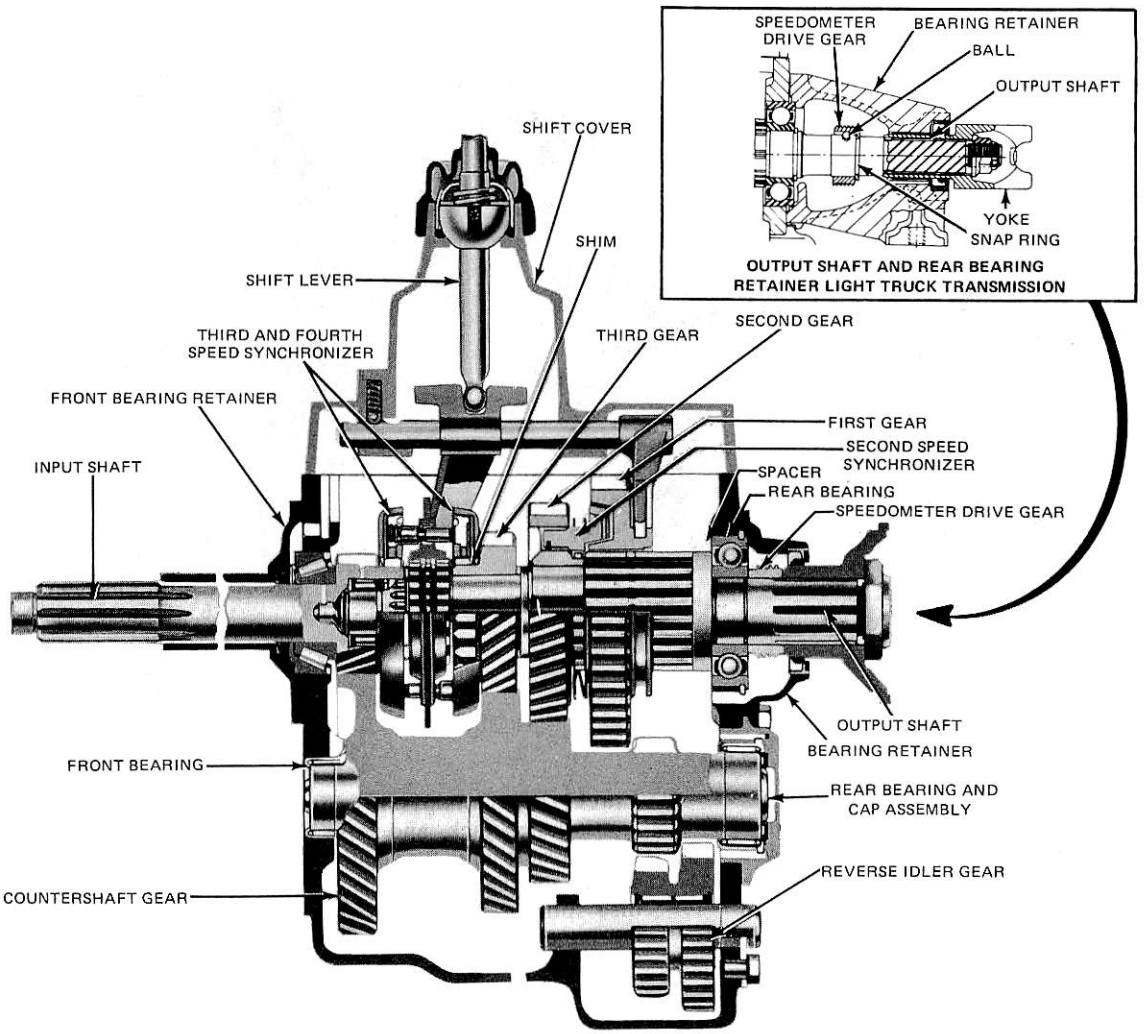

FIG. 2 Transmission Sectional View

REMOVAL AND INSTALLATION

TRANSMISSION

Refer to Figs. 2, 3 and 4 for various installation views.

Removal

1. On F-, LN-or B-Series truck, remove the rubber boot and floor mat.
2. On a F-, LN-or B-Series truck, remove the floor pan transmission cover plate. Remove the weather pad on F-100, F-350. It may be necessary first to remove the seat assembly.
3. Disconnect the back-up light switch located in the rear of the gearshift housing cover.
4. Raise the truck and position safety stands. Position a transmission jack under the transmission, and disconnect the speedometer cable.
5. Disconnect the parking brake lever from its linkage, and remove the gearshift housing. On a C-Series truck, disconnect the parking brake cable and bracket at the transmission.
6. Disconnect the drive shaft or coupling shaft. Remove the bolts that attach the coupling shaft center support to the crossmember and wire the coupling shaft and drive shaft to one side. In F-100-350 Series Trucks, remove the transmission rear support.
7. On C-Series trucks, remove the two transmission upper mounting nuts at the clutch housing (Fig. 3).
8. Remove the transmission attaching bolts at the clutch housing, and remove the transmission.

Installation

Before installing the transmission,

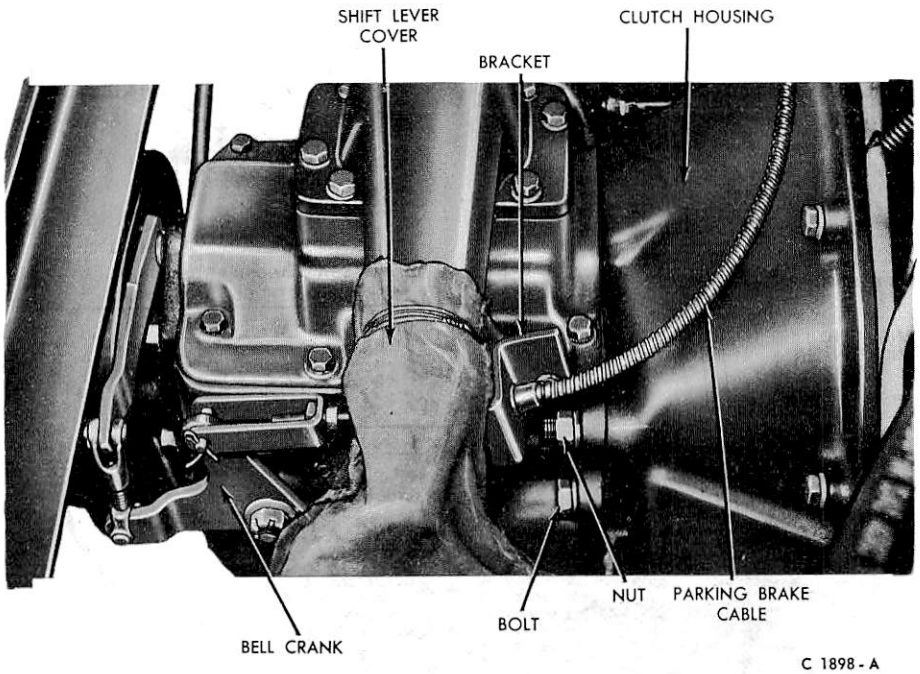

FIG. 3 Transmission Installed—C-Series

apply a light film of lubricant (C1AZ-19590-B) to the release bearing inner hub surfaces and the release lever fulcrum and fork. Care must be exercised to avoid excessive grease contaminating the clutch disc.

1. Place the transmission on a transmission jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork.
2. Install guide studs in the clutch housing and slide the transmission forward on the guide studs until it is in position on the clutch housing. Install the attaching bolts and nuts, and torque them to specifications. Remove the guide studs and install the two lower attaching bolts.
3. Install the bolts attaching the coupling shaft center support to the crossmember. Torque the bolts to specifications.
4. Connect the drive shaft or coupling shaft and the speedometer cable. Torque the U-joint nuts to specification. On F-100-350 Series trucks, install the transmission rear support.
5. Install the gearshift housing and connect the brake to the transmission.
6. Connect the back-up light switch wire.
7. On an F-, LN-or B-Series truck, install the weather pad and the transmission cover plate. Install the seat assembly if it was removed.
8. On an F-, LN-or B-Series truck, install the weather pad, the pad retainer, the floor mat and rubber boot.

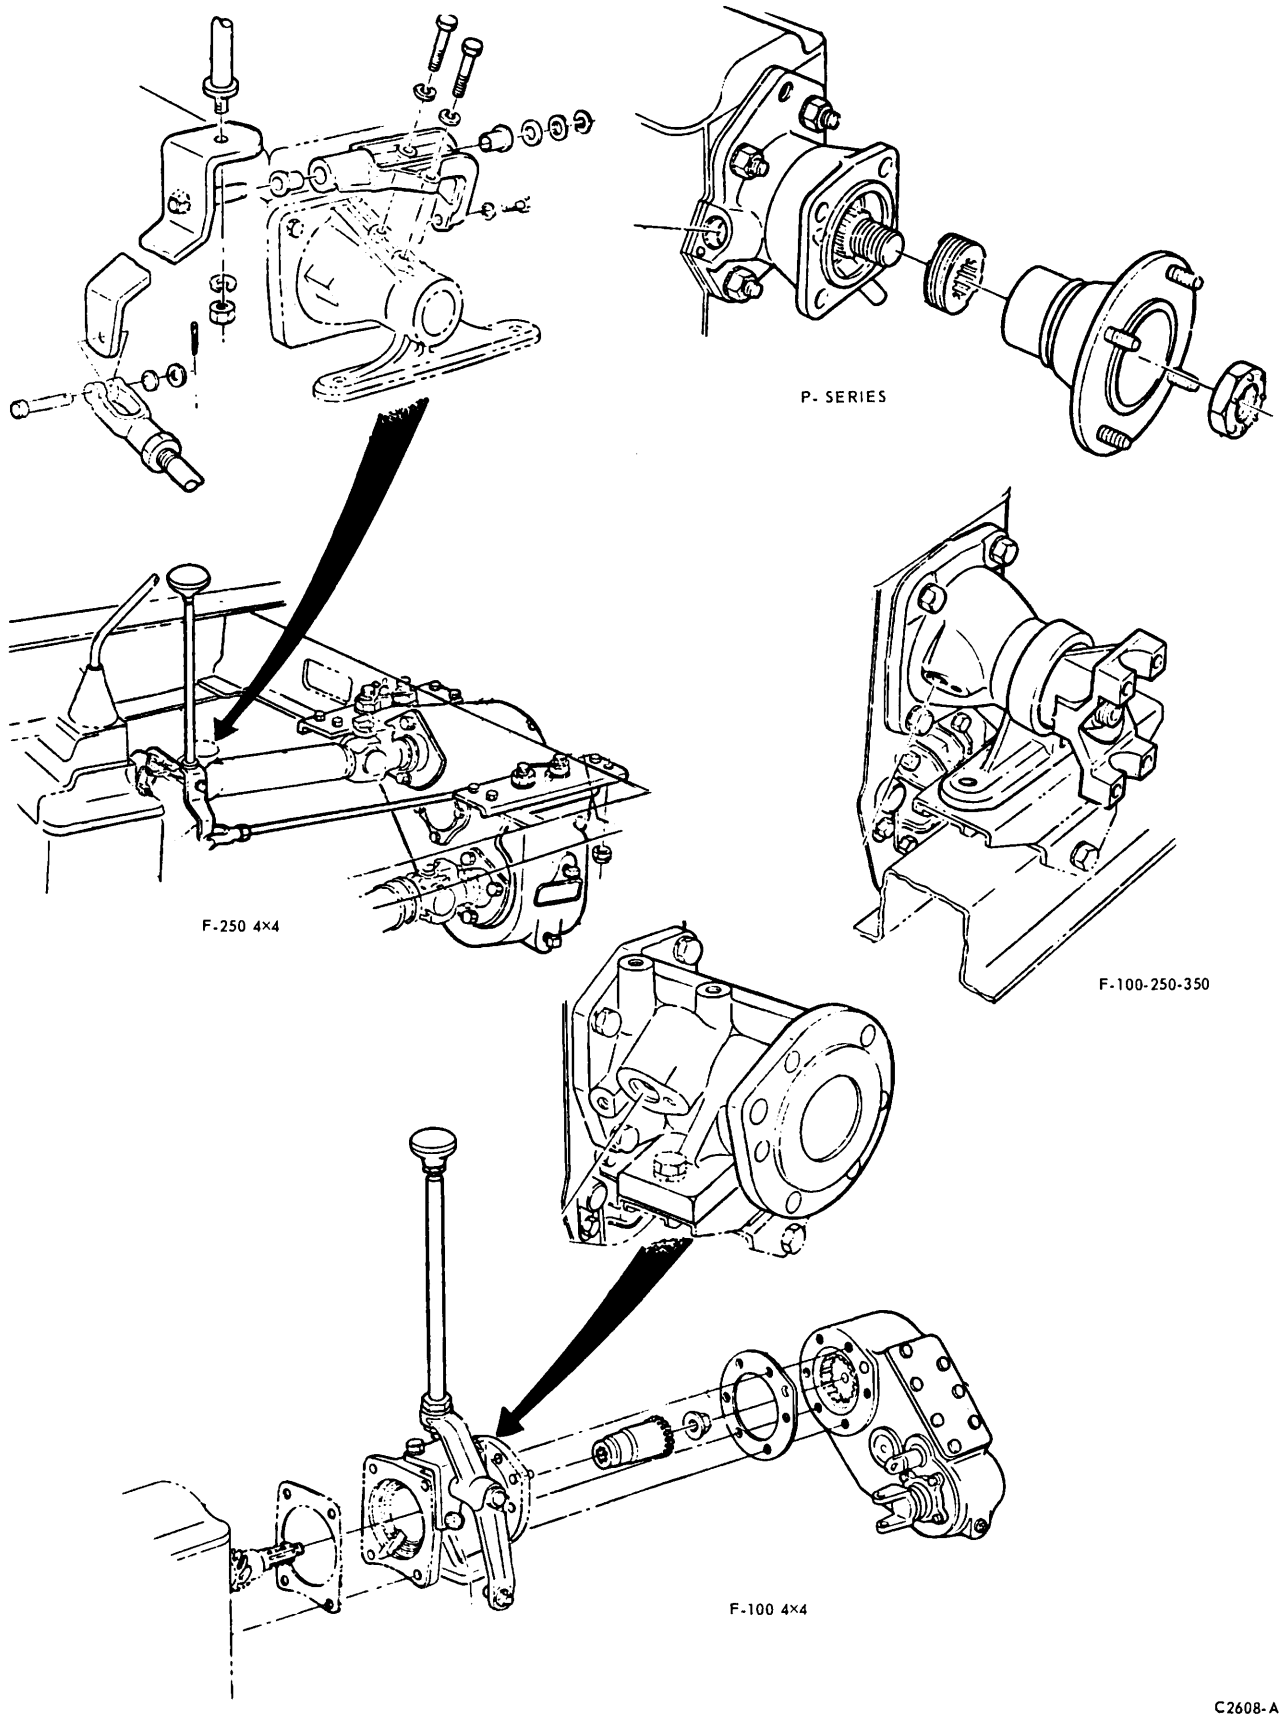

FIG. 4 Light Truck Installations—Model 435 Transmission

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Place the gearshift lever in the neutral position, remove the gearshift cover attaching bolts, and remove the cover.
2. Lock the transmission in two gears, and remove the output flange nut. Remove the parking brake drum brake and flange.
3. Remove the extension housing attaching bolts or nuts. Remove the extension housing from the output shaft.
4. Slip the speedometer drive gear off the output shaft.
5. Remove the front bearing retainer attaching bolts. Remove the retainer and gasket.
6. Rotate the input gear as required to align the notch in the input gear clutch teeth with the countershaft drive gear teeth. remove the input gear and tapered roller bearing from the transmission (Fig. 5).
7. Remove the output shaft bearing (Fig. 6).
8. Remove the roller-type thrust bearing from the front of the main shaft.
9. Slide the third and fourth-speed synchronizer off the output shaft and remove it from the case.
10. Lift the output shaft from the case as shown in Fig. 7.
11. Remove the reverse idler gear shaft retainer from the rear of the case (Fig. 7). Secure the puller T50T0100-A and Adapter T50T-7140-B to the shaft. Hold the gear to prevent it from dropping, and then remove the idler shaft.
12. Position the transmission so the front of the case is facing down. Remove the countershaft gear rear bearing cap attaching bolts. Tap the cap with a soft-faced hammer to free it from the case. Remove the cap, race thrust bearing, and gasket (Fig. 8). Lift the gear from the case.

Assembly

Coat all parts with the specified transmission lubricant to prevent scoring when the transmission is first operated.

1. Place the input shaft on the output shaft and install the complete assembly in a vise as shown in Fig. 9.

Check the distance between the synchronizer and input shaft gear. If the distance is more than 0.043-0.053 inch, install the necessary thickness of shims between the third-speed gear and the synchronizer brake drum. After the proper thickness of shims has been established, remove the input shaft from the output shaft.

2. Position the transmission case with the front facing down.
3. Apply a thin film of grease on the front thrust washer and place it in position in the front of the case. The thrust washer is bored off-center; therefore, make sure that the tangs match the slots in the case boss.
4. Place the countershaft gear in the case.
5. Place the rear thrust bearing and then the bearing race on the rear of the countershaft gear (Fig. 8).
6. Install a new gasket on the bearing cap. Then coat the bore of the bearing cap with grease to retain the roller bearings and insert the bearings. Install the bearing cap on the rear of the case. Torque the attaching bolts to specifications.
7. Install the reverse idler gear in the case with the larger gear toward the rear of the case. Coat the rear of the reverse idler gear shaft with sealer before installing the retainer. Secure the idler shaft retainer with a bolt.
8. Position the output shaft assembly in the case.
9. Place a wood block in the front of the case as shown in Fig. 10. Drive the bearing onto the rear of the output shaft while holding the front of the shaft against the block.
10. Install the rear extension housing on the transmission. Do not install the yoke until the output shaft end play has been checked. On transmissions equipped with a parking brake support, the yoke and retaining nut must be installed before the output shaft end play is checked.
11. Position the input shaft so that the cutaway portion of the clutch teeth is facing down, then position the gear in the case.
12. Install the bearing retainer with no gasket or capscrews.

Using Tool T-64T-7000-A to hold the shaft and retainer concentric, measure the clearance between the retainer and the case (Fig. 11). Install a gasket shim pack 0.010-0.015 inch between the retainer and the case to obtain the required 0.007 to 0.017 inch input shaft end play. After the front retainer bolts have been torqued, recheck the end play.

When the input shaft end play has been established, recheck the synchronizer clearance; it should be 0.050 to 0.070 inch. Adjust the synchronizer clearance if required.

13. Install the parking brake shoes.
14. Lubricate the extension housing bushing and seal and U-*joint flange* with ball joint grease.
15. Install the speedometer drive gear, companion flange, brake drum and the flange attaching nut. Lock the transmission in two gears and torque the nut to specifications.
16. Place the transmission gears in neutral.
17. Install a new cover gasket and the cover.
18. Fill the transmission with lubricant through the speedometer cable attachment opening in the rear bearing retainer until the lubricant reaches the lower level of the regular filler opening.

SUB-ASSEMBLIES

GEARSHIFT HOUSING

Disassembly

1. The shift cover should be disassembled only if it is necessary to replace a shift fork, shift rail, or the cover itself.
2. Slide the boot off the cap (if so equipped).
3. Using special Tool T73T-7220-A, turn the cap counterclockwise and remove the lever from the cover.
4. Remove the back-up lamp switch from the housing (Fig. 13).
5. Remove the roll pin from the first and second-speed shift fork as shown in Fig. 12. Remove the roll pin from the gate in the same manner. To remove the roll pin, the screw extractor should be entered into the pin by tapping lightly on the fabricated handle. The handle should be turned slowly counterclockwise while being tapped. When the screw extractor grips the roll pin stop tapping, pull lightly, and continue turning until the pin is removed.
6. Push the shifter shaft out through the front to force the plug out of the cover. Cover the detent ball access hole in the cover to prevent the ball and the spring from flying out as the shaft clears the hole. Remove the shaft fork and the gate.
7. Remove the third and fourth-speed

shifter shaft in the same manner, then the reverse shifter shaft.
8. Compress the reverse gear plunger and remove the retaining clip. Remove the plunger and the spring from the gate (Fig. 13).

Assembly

1. Assemble the spring on the reverse gear plunger (Fig. 13) and hold it in the reverse shift gate. Compress it in the gate and install the retaining clip.
2. Enter the reverse shifter shaft in the cover and place the detent spring and ball in position. Depress the ball and slide the shifter shaft over it.
3. Install the gate and the fork on the shaft. Install a new roll pin in the gate and in the fork.
4. Apply a film of sealer in the plug seat at the front of the cover. Install a new plug in the reverse shifter shaft bore.
5. Place the reverse fork in the neutral position.
6. Install the two interlock plungers in their bores (Fig. 13).
7. Insert the interlock pin in the third and fourth-speed shifter shaft. Install the shaft in the same manner as the reverse shifter shaft mechanism.
8. Install the first and second-speed shifter shaft in the same manner making sure that the interlock plunger is in place.
9. Lubricate the spherical ball seat. Position the shift lever and cap in place.
10. Install the back-up lamp switch and T.R.S. switch and torque to specifications.

COUNTERSHAFT GEAR FRONT BEARING

Disassembly

1. Drive the countershaft gear front bearing from the case. The bearing can be driven out from the outside of the case. Do not lose any roller bearings when the cage is pressed out.

Assembly

1. Carefully press the bearing into the case until the cage is flush with the front of the case. Retain the roller bearings in the bearing cage with grease.

COUNTERSHAFT GEAR REAR BEARING

1. Position the transmission so the front of the case is facing down.
2. If uncaged bearings are re-used the loose rollers (or needles) can be held in place with a suitable grease. This is not required with the caged type used for service replacement. Position the bearings in the cap.
3. Position the race thrust bearing and the cap. Torque the attaching bolts to specification.

INPUT SHAFT BEARING RACE

Disassembly

1. Pull the bearing race from the front bearing retainer with Puller T50T-100-A and OTC-943.

Assembly

1. Press a new race into the front bearing retainer with the tool shown in Fig. 14.

INPUT SHAFT SEAL

Disassembly

1. Pull the input shaft seal (Fig. 5) with Tool T58L-101-A and slide hammer Tool T50T-100-A.

Assembly

1. Press a new seal into place in the retainer making sure that the lip of the seal is toward the mounting surface.

INPUT SHAFT BEARING

Disassembly

1. Remove the tapered roller bearing from the input shaft with Tool T64T-7025-A and T54T-4625-B1.

Assembly

1. Position Tool 4261-BA in an Arbor Press as shown in Fig. 15. Place a wood block on the input gear and press the gear into the bearings until it contacts the bearing inner race.

INPUT SHAFT ROLLER BEARINGS

Disassembly

1. Remove the snap ring and retaining washer from the shaft.
2. Remove the bearings from the input shaft bore.

Assembly

1. Coat the bore of the input shaft gear with a thin film of grease.
2. Install the 14 roller bearings in the bore of the input shaft. Slide the final roller axially into place. Secure the bearings with the retaining washer and the snap ring.

REVERSE IDLER GEAR BEARINGS

On F-100-350 and P-Series production gears, an idler gear and an integral bronze bushing is used (Fig. 5). For service replacement of the reverse idler gear on these models the gear and roller bearings are to be used, the same as on other models. The service reverse idler gear and bearings are serviced only as an assembly. Once the bearing lock ring snaps into place it cannot be removed without destroying either the gear or the bearing.

FIRST-SPEED GEAR

Disassembly

1. Remove sliding first-speed gear and output shaft from the transmission.
2. Mark the gear and output shaft so the gear and shaft splines can be assembled in the same position. Remove the gear from the output shaft. Do not lose the spline springs.

Assembly

1. **If a new gear and/or shaft is being installed, select-fit the gear to the shaft for the best sliding action. Do the same if the first speed gear has been sticking on the shaft splines.** Position the spline springs on the coast side of the spline teeth of the slider gear. To facilitate assembly, use a daub of grease to retain the springs on the sides of the spline teeth. Two notches have been machined on the hub of the slider gear to identify the location of the relieved splines.
2. Place the new slider gear assembly in its position on the output shaft.

SECOND-SPEED GEAR

Disassembly

1. Slide the third-speed gear, first-speed gear stop, and the first-speed gear off the output shaft. Do not lose the slider gear springs.
2. Carefully pry up on one end of the two piece snap ring and remove it from the shaft.**If any damage to the ring results from this, it should not be re-used.**
3. Slide the second-speed gear and synchronizer brake off the shaft.
4. Remove the snap ring from the synchronizer brake pins. Separate the brake and spring from the second-speed gear.

Assembly

1. Assemble the spring and synchronizer brake to the second-speed gear. Secure the brake with the snap ring making sure that the snap ring tangs are away from the gear.
2. Slide the second-speed gear onto the front of the output shaft making sure that the synchronizer brake is toward the rear. Secure the gear to the shaft with the two piece snap ring.
3. Slide the spring loaded first-speed gear and the gear stop (Fig. 5) onto the rear of the shaft.
4. Slide the third-speed gear, synchronizer shim (if required) and the third and fourth-speed synchronizer and the roller type thrust bearing on the front of the shaft.

DESCRIPTION

TRANSMISSION

The Model 542 (Fig. 1) is a synchromesh transmission. The mainshaft gears, except first-speed gear, are helical type and are in constant mesh with mating gears on the countershaft. The first and reverse gears have straight cut spur-type teeth. Two synchronizer mechanisms are used for smooth shifting without gear clash.

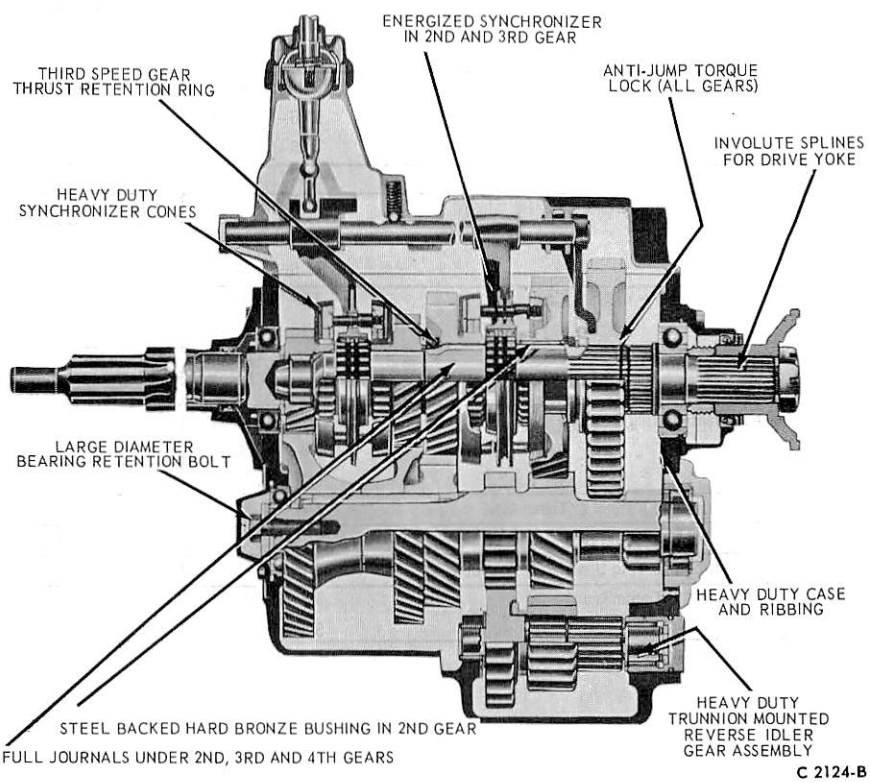

FIG. 1 New Process 542 Four-Speed Transmission

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate. Loosen the two nuts that secure the top of the transmission to the clutch housing studs.

If the vehicle is not raised on a hoist, it may be necessary to remove the parking brake lever before the transmission can be removed. Remove the shift lever using special Tool T73T-7220-A.

2. Drain the transmission. Disconnect the drive shaft (or the coupling shaft) at the parking brake drum. If the vehicle is equipped with a coupling shaft support, disconnect the support bracket, and remove the coupling shaft.
3. Disconnect the parking brake adjusting rod, and disconnect the speedometer cable.
4. Remove the dust cover from the bottom of the clutch housing. Position a transmission jack under the transmission. Remove the top nuts, and the bottom bolts and lock washers that secure the transmission to the clutch housing.
5. Move the transmission rearward until the input shaft splines clear housing. Be careful that the clutch release bearing and hub do not drop out of the release lever fork. Lower the transmission to the floor.

Installation

1. Place the transmission on a transmission jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. Install the lock washers, the top nuts, and the bottom bolts, and torque the bolts and nuts to specifications. Install the dust cover on the bottom of the clutch housing. Connect the speedometer cable.
3. Connect the parking brake adjusting rod.
4. Install the coupling shaft in the support bracket, and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission. Install the shift lever using special Tool T73T-7220-A.
5. Lower the vehicle to the floor, and install the floor plate and the floor mat. Fill the transmission to the correct level with the proper lubricant.
6. Check the clutch pedal free travel, and adjust it if necessary.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Shift the transmission into second gear, and remove the gear shift cover attaching bolts. Raise the cover and turn the output shaft to position one of the second and third-speed blocking ring pins directly over the center of the output shaft (Fig. 2). While lifting the cover off the case, rotate it slowly in a clockwise direction and tilt it toward the right side of the transmission case. Push the low sliding gear backward to clear the fork.
2. Lock the output shaft by shifting the transmission into two gears at one time and remove the output shaft nut. Remove the parking brake drum and spline flange. Disconnect the brake actuating lever, and remove the brake shoe assembly. Remove the bearing retainer and the speedometer gear.
3. Remove the retaining snap ring from the input shaft bearing outer race and remove the input shaft and bearing from the case. Remove the snap ring and washer retaining the output shaft pilot roller bearings in the input shaft bore and remove the roller bearings.
4. Remove the output shaft bearing (Fig. 3). Slide the output shaft toward the rear of the case, and remove the front synchronizer blocking rings and sleeve. Remove the shims from the fourth-speed gear. Remove the output shaft assembly from the case.
5. Remove the reverse idler shaft lock plate, and tap the front of the idler shaft until the retainer can be removed from the case. Remove the thrust bearing from the rear of the shaft and the thrust washer and O-ring from the retainer. Remove the shaft and front bearing from the case (Fig. 2).
6. Remove the four countershaft rear bearing and retainer cap bolts. Remove the countershaft front bearing retainer and gasket. Remove the front bearing attaching bolt. With a drift, drive the countershaft through the front bearing toward the rear, until the countershaft rear bearing and retainer cap comes out of the case. Remove the bearing and cap from the countershaft. Lift the countershaft assembly out of the case. Remove the thrust washer from the front of the countershaft. Remove the countershaft front bearing from the case.

Assembly

1. Install the snap ring on the countershaft front bearing outer race, and tap the bearing into the case. Install the front bearing outer retainer without a gasket. Place the thrust washer (spacer) on the front of the assembled countershaft, and place the countershaft in the front bearing. Tap the countershaft from the rear until the thrust washer (spacer) bottoms on the front bearing. Install the countershaft rear bearing and retainer cap, and gasket. Torque the bolts to specifications. Remove the countershaft front bearing outer retainer. Install the inner retainer that holds the countershaft on the bearing inner race. Torque the inner retainer bolt to specifications. Install the front bearing outer retainer and gasket. Tighten the retainer bolts to specifications.
2. Place the idler gear on the idler shaft

with the shift fork groove toward the front. Install the thrust washer on the front of the idler shaft with the tang toward the front. Place the shaft and gear in the case, aligning the thrust washer tang with the slot in the case. Install the thrust bearing on the rear of the idler shaft and the thrust washer in the rear bearing retainer. Place a new O-ring in the retainer groove. Install the rear bearing retainer, lock and bolt.

3. Install the output shaft assembly in the case. Place a hardwood block at the front of the output shaft, and drive the output shaft bearing onto the shaft, using the tool shown in Fig. 4.

Remove the hardwood block, and install the fourth and fifth-speed synchronizer. Drive the output shaft bearing into the case with the tool shown in Fig. 4.

4. Using a driver, install the input shaft and bearing in the case. Shift the transmission into two gears, at one time and install the bearing attaching nut. Stake the nut. Install the input shaft bearing retainer without a gasket. Tighten the retainer bolts only enough to bottom the retainer on the bearing snap ring. With a feeler gauge, check the clearance between the bearing retainer and case. This clearance should be 0.003-0.006 inch.

Remove the retainer, and select a gasket pack which will insure a seal at the outer edge of the retainer and at the same time eliminate end play between the retainer and bearing outer race snap ring. Torque the bolts to specifications.

5. Install the spacer and speedometer gear on the output shaft. Check the output shaft bearing retainer oil seal. Replace if damaged, making sure that the open face of the seal faces the transmission (Fig. 2). Place a new gasket on the retainer, and install the retainer on the case. Torque the bolts to specifications.
6. Install the parking brake shoe assembly. Position the universal joint flange and brake drum on the output shaft. After shifting the transmission into 2 gears at one time, install the output shaft nut and torque to specifications. When lining up the cotter pin holes, always tighten the nut.
7. Shift the transmission into fourth gear. With 2 feeler gauges, check the clearance between the fourth-speed synchronizer outer ring and the fourth-speed gear (Fig. 5). Position the synchronizer so that one pin is directly above the center of the output shaft, and do not rock the synchronizer while making this check. If the clearance is not between 0.050 and 0.070 inch, change the shim which was installed on the front side of the fourth-speed gear. Shims are available in the following thickness: 0.009-0.011, 0.014-0.016 inch.
8. Shift the second and third-speed synchronizer into second gear. Shift all other gears into neutral. Shift the second and third-speed shifter fork into second gear.
9. Place a new gasket on the gear shift cover, and install it on the case. **There are two special bolts that fasten the gear shift housing to the case. They are locating bolts and are installed, one on each side of the housing at the second hole from the front. Install these and the remaining bolts, and torque to specifications.**
10. Install and adjust the parking brake assembly.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the snap ring at the front of the output shaft (Fig. 2), and remove the synchronizer hub and fourth-speed gear.
2. Using snap ring pliers, remove the snap ring at the front of the third-speed gear. Remove the gear and thrust washer. Remove the second and third-speed synchronizer. Slide the low and reverse sliding gear off the rear of the output shaft.
3. Remove the second-speed gear.

Assembly

1. Slide the second-speed gear onto the output shaft. Install the washer and the retaining snap ring.
2. Slide the low and reverse sliding gear onto the output shaft, with the fork groove toward the front. Install the second and third-speed synchronizer (Fig. 2) with the long hub on the sliding clutch toward the front of the shaft.
3. Install the third-speed gear on the output shaft, with the clutch teeth toward the rear. Install the washer snap ring.
4. Place the fourth-speed gear on the output shaft, with the clutch teeth toward the front. Slide the shims over the fourth-speed clutch teeth. Place the fourth and fifth-speed synchronizer clutch hub on the output shaft, with the oil slots toward the rear. Install the snap ring that retains the synchronizer hub. Check the clearance between the snap ring and hub. Maximum clearance is 0.0003 inch. Replacement snap rings are available in the following thicknesses: 0.086-0.088, 0.089-0.091, 0.092-0.094, 0.095-0.097 inch.

COUNTERSHAFT OR GEARS

Disassembly

If any of the countershaft gears are to be replaced, press the gears off the shaft.

Assembly

Apply lubricant to the gear bores, and press the gears onto the countershaft.

INPUT SHAFT OR BEARING

Disassembly

If the input shaft bearing is to be replaced use Tool T53T-7065-A (Fig. 6) to remove the bearing from the shaft.

Assembly

Press the bearing onto the input shaft. Place the output shaft pilot roller bearings in the input shaft and install the retainer and snap ring.

GEAR SHIFT COVER

Disassembly

1. Mount the cover in a bench fixture or soft-jawed vise. Mark each fork and gate for location at assembly (Fig. 7). Shift all the shifter shafts into neutral position.
2. With a punch, drive the four expansion plugs out of the housing (Fig. 8).
3. **With a screw extractor, remove the pins that hold the forks and gates on the shifter shafts.**
4. Insert a pin punch in any one of the shifter shaft pin holes and slide the shaft through the rear of the housing. As the shaft clears the front support, catch the detent ball and spring. Mark the end of the shifter shaft to insure proper assembly. The remaining shafts may be removed in the same manner.

Assembly

1. Install the reverse shifter shaft detent ball and spring in the housing. Install the reverse shifter shaft, fork and gate.
2. Place the interlocking balls in the housing. Install the remaining shifter shafts, forks, gates, and detent balls. The interlocking pins must be installed in the center shafts (Fig. 9).
3. Check the operation of the interlocking system. Install the retaining pins in the forks and gates.

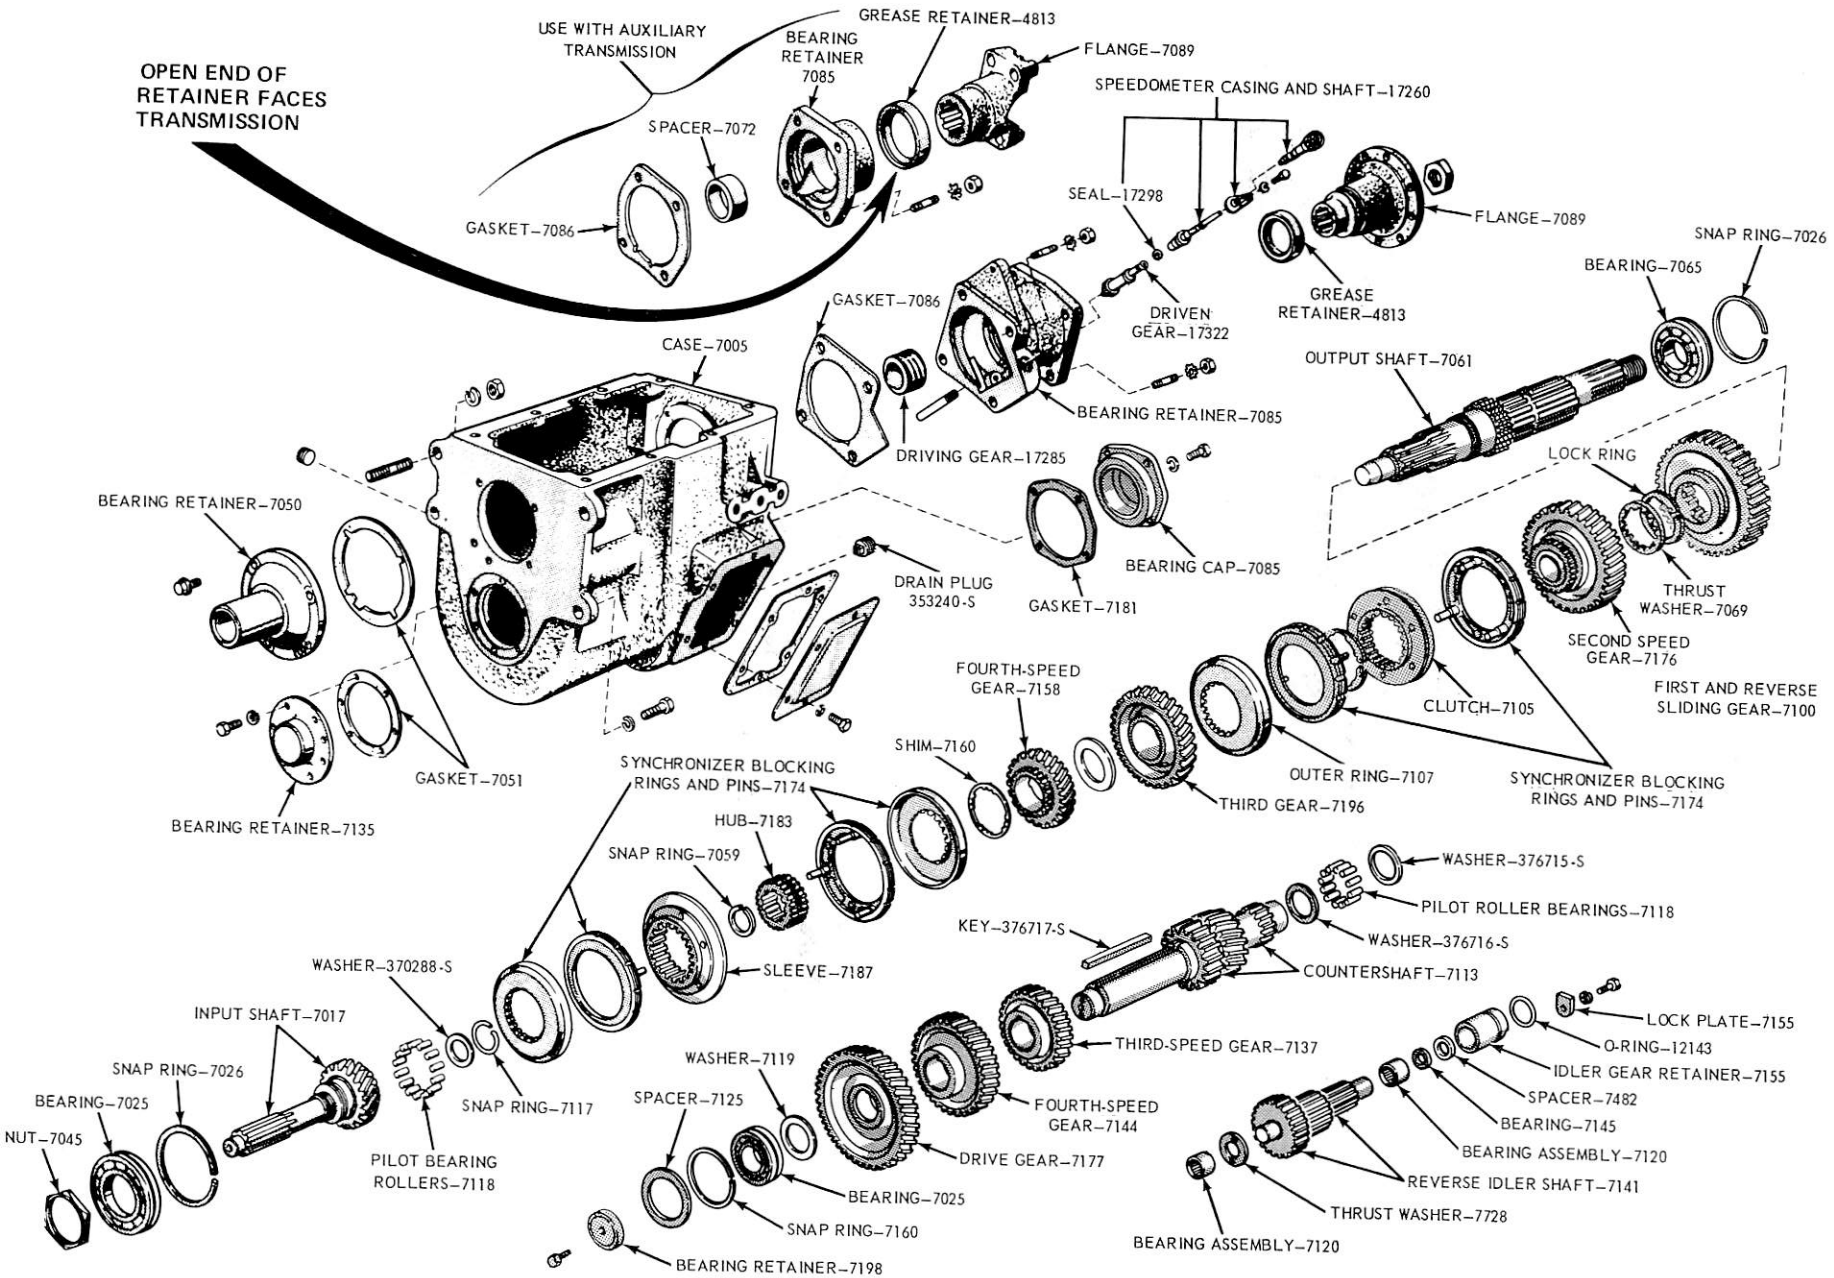

FIG. 2 Transmission Disassembled

4. Coat the outer edges of new expansion plugs with an oil-resistant sealer, and install them in the housing. Expand the plugs with a flat faced bar or punch by striking them in the center.
5. Check the operation of the interlock system by moving one outside rail. If the opposite outside rail can be moved, the system is not operating.

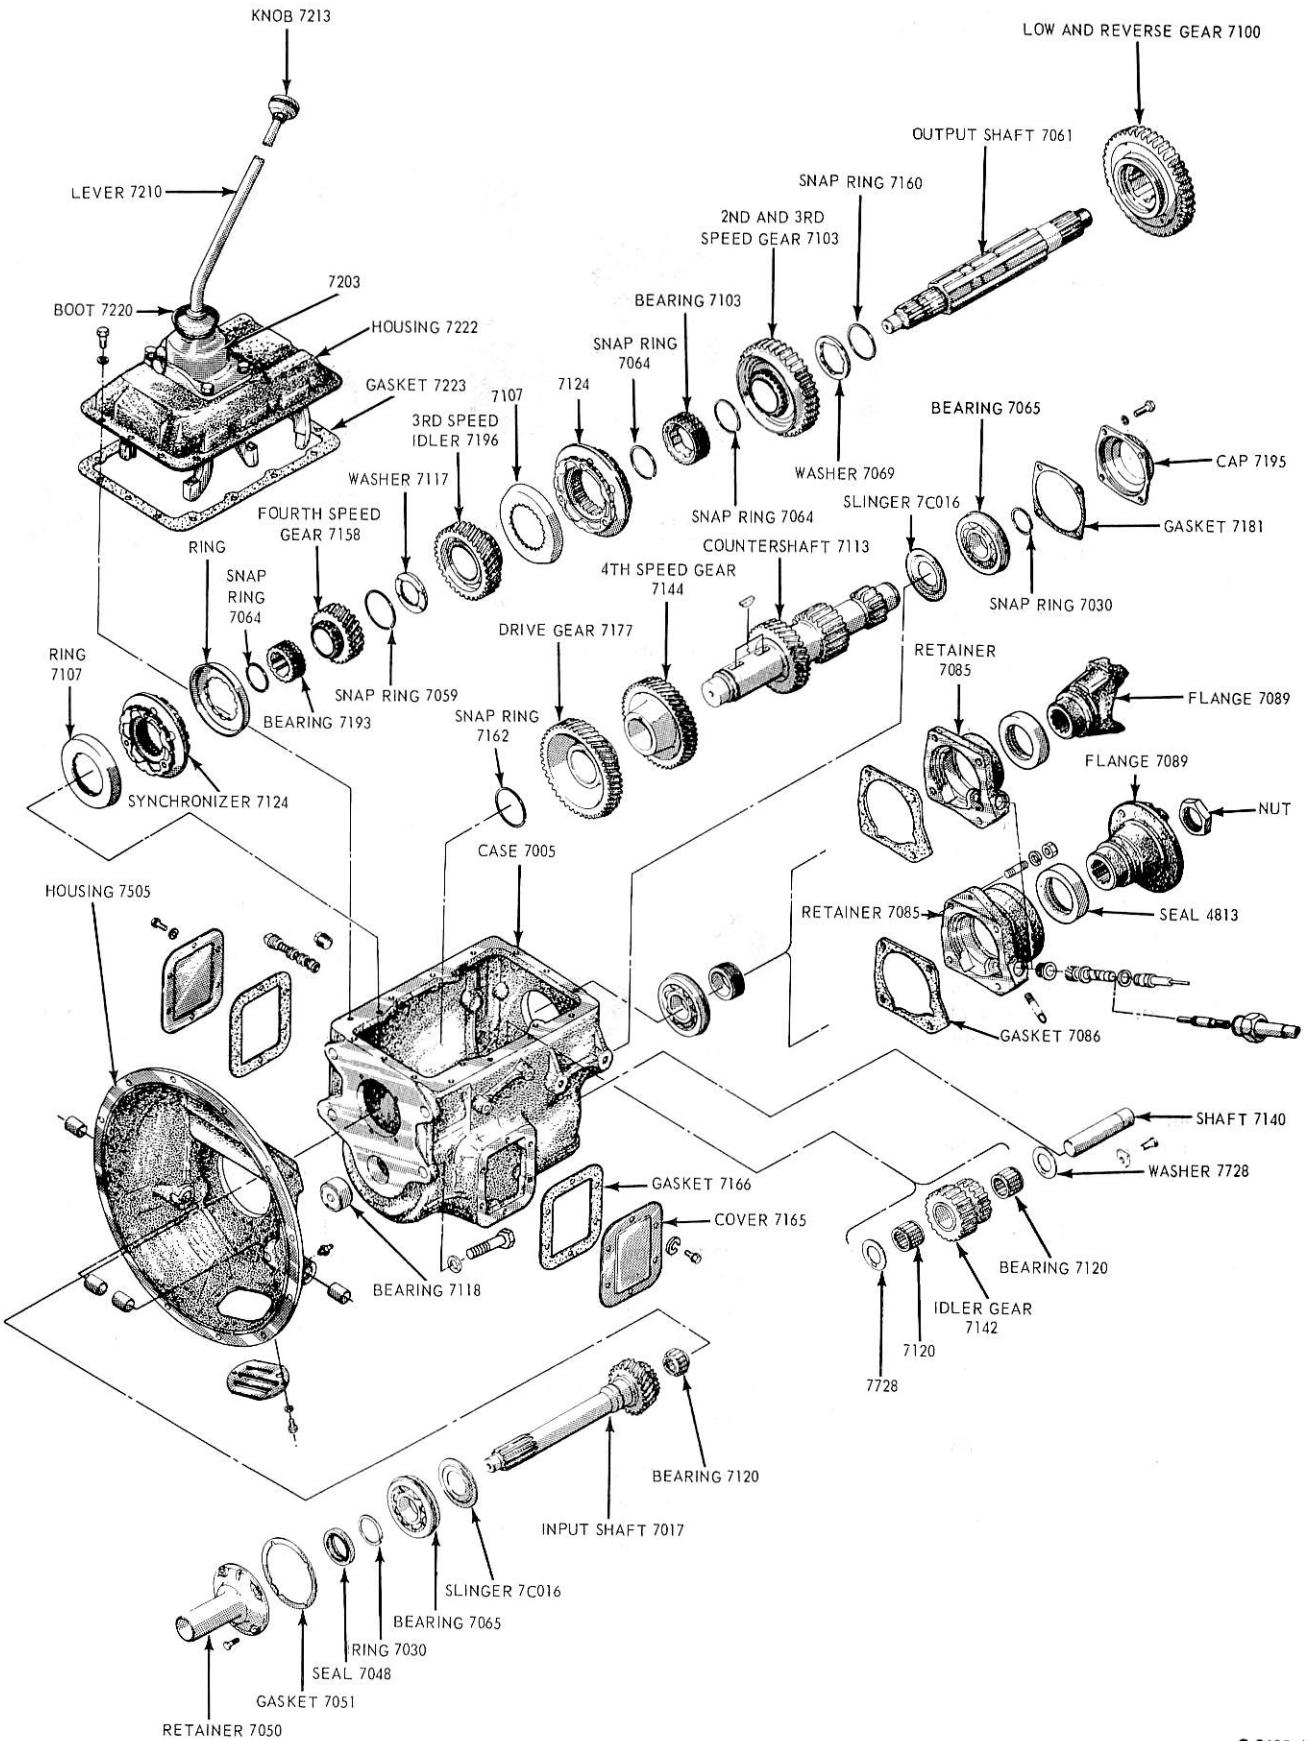
DESCRIPTION

TRANSMISSION

The heavy-duty 5-speed Synchro-Silent Clark 280-V series transmission (Fig. 1) is available with either a direct drive ratio in fifth gear or an overdrive ratio in fifth gear. The overdrive ratio is reached through gearing in the transmission and not through a separate overdrive unit.

The overdrive and the direct drive type of transmission differ in gear ratios at all speeds and in the power flow path through the gears. However, the construction of these transmissions is basically the same.



C 2695-A

FIG. 1 Clark 280 Series Transmission—Disassembled

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate.

Remove the gear shift lever housing and disconnect the parking brake lever. Cover the case opening.

2. On a C-Series model, shift the transmission into neutral, release the lock, and tilt the cab forward. Remove the rear cross-shaft housing bolts. Tie the housing so that it does not fall. If necessary to provide room for removal of the transmission, raise the rear of the truck and install safety stands.
3. Drain the transmission. Disconnect the drive shaft (or the coupling shaft) at the parking brake drum. If the truck is equipped with a coupling shaft support, disconnect the support bracket, and remove the coupling shaft.
4. Disconnect the parking brake adjusting rod, and disconnect the speedometer cable. Remove the driven gear and its bearing.
5. Remove the dust cover from the bottom of the clutch housing. Position a transmission jack under the transmission. Remove the top nuts, and the bottom bolts and lock washers that secure the transmission to the clutch housing.
6. Move the transmission to the rear until the input shaft splines clear the clutch housing. Be careful that the clutch release bearing and hub do not drop out of the release lever fork. Lower the transmission to the floor.

Installation

1. Place the transmission on a transmission jack, and raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork. Slide the transmission forward until it is in a position on the clutch housing.

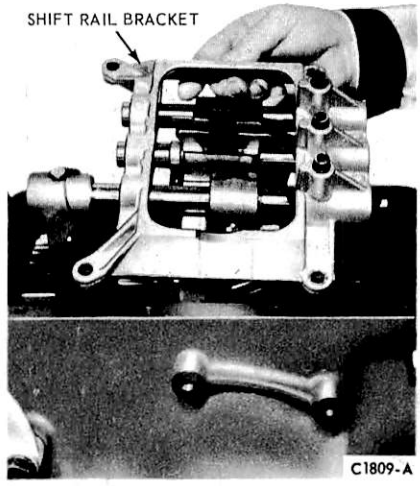


FIG. 2 Removing Shift Rod Support Assembly

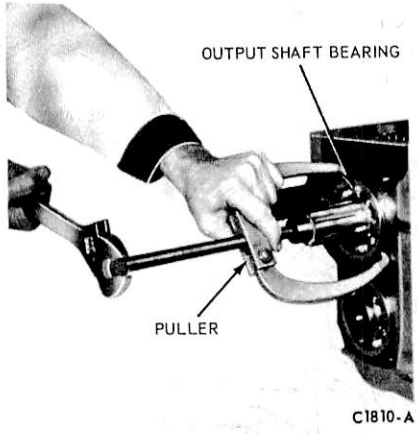

FIG. 3 Removing Output Shaft Rear Bearing

2. On a C-Series model, position the cross-shaft housing on the transmission case adapter, and install the mounting bolts. Torque the bolts to specification.
3. Install the lock washers, the top nuts, and the bottom bolts, and torque the bolts and nuts to specifications. Install the dust cover on the bottom of the clutch housing.

FIG. 4 Installing Countershaft Rear Bearing

Position the speedometer driven gear bearing and the gear, and connect the speedometer cable.

4. Connect the parking brake adjusting rod.
5. Install the coupling shaft in the support bracket, and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
6. Install the shift lever housing. **When positioning the gear shift lever housing, always lower it straight down onto the gear shift housing.** Torque the gate plunger retainer to specification.
7. Lower the truck to the floor, and install the floor plate and the floor mat. Fill the transmission with the correct amount of proper lubricant. Adjust the remote control shift linkage.
8. Check the clutch pedal free travel, and adjust it if necessary.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Remove the gear shift housing cover and remove the shift rods as an assembly (Fig. 2).
2. Remove the parking brake drum anchor clip screw. Remove the brake band jam nuts and locating screw.
3. Remove the brake band adjusting nut and bolt, then remove the two brake release springs and the cam lever shoe.
4. Slide the brake band off the drum and remove the anchor clip spring.
5. Lock the transmission in two gears and remove the brake drum retaining nut. Remove the brake drum from the output shaft.
6. Remove the output shaft rear bearing retainer and speedometer drive gear.
7. Remove the countershaft rear bearing retainer, then remove the bearing snap ring.
8. Remove the input shaft bearing retainer and pull the input shaft out of the case. **Be careful not to drop output shaft pilot bearing rollers into the transmission case.**
9. Force the output shaft rearward until the rear bearing is exposed. Using a bearing puller, remove the rear bearing from the bore (Fig. 3).
10. Lift the output shaft from the case.
11. Remove the reverse idler shaft using Tool T50T-100-A. Lift the reverse idler gear, bearing and thrust washers from the case.
12. Force the countershaft rearward until the rear bearing is exposed. Remove the bearing and oil slinger with a suitable puller.
13. Lift the countershaft from the case.

Assembly

1. Coat the front countershaft needle bearings with grease and install them in the front countershaft bore.
2. Tip the rear of the countershaft down and lower it into the case. Push the countershaft forward and insert the shaft into the front bearing.
3. Position the countershaft rear bearing oil slinger and bearing on the shaft. Drive the bearing into the bore (Fig. 4). The countershaft drive gear should be supported while driving the shaft to prevent damage to the front bearing.
4. Coat the reverse idler thrust washers with grease and position them in the case.
5. Insert the two roller bearings in the reverse idler gear bore. Place the gear assembly in position in the transmission case, with the small gear toward the rear of the case.
6. Insert the reverse idler shaft through the hole in the case, through the reverse idler gear and into the forward support boss. Drive the reverse idler shaft into the case until the slot in the shaft is lined up with the lock bolt hole. Install the retainer in the slot and secure the retainer with the lock bolt. Torque the bolt to specifications.
7. Tilt the rear of the output shaft assembly downward and insert the end of the shaft through the output shaft bore in the case. Lower the front end of the output shaft until it is in line with the pilot bearing opening. Move the assembly forward into position.
8. Insert the pilot bearing in the input shaft bore.
9. Position the input shaft and bearing assembly in the forward end of the transmission case. Tap the front end of the shaft with a soft hammer until the snap ring is seated against the case. Be sure the clutching teeth of the input shaft gear mesh with the fifth-speed synchronizer without bind.
10. Position a new gasket on the input shaft bearing retainer. **Be sure that the oil return holes in the retainer and gasket are aligned with the return hole in the case.**
11. Install the lock washers and bolts on the input shaft bearing retainer and torque the bolts to specification.
12. Position the output shaft rear bearing on the shaft and drive the bearing into its bore until the snap ring is seated against the case.
13. Position the countershaft rear bearing cap and gasket on the case and install the lock washers and bolts. Torque the bolts to specification.
14. After installing the speedometer drive gear on the output shaft, position a new oil seal in the output shaft bearing retainer. Be sure the seal is correctly installed. Position a new gasket and the bearing retainer on the case and install the lock washers and bolts. Torque the bolts to specification.
15. Install the parking brake drum assembly and companion flange assembly.
16. Shift all rods to the neutral position and install the gear shift housing assembly in the transmission case. Be sure the shift forks engage the slots on the gears. Install the shift rod support assembly bolts and torque the bolts to specification. Install the three locking bolts and springs in the support housing (Fig. 5).
17. Install a new transmission cover gasket on the case and position the top cover. Install the cover retaining bolts and torque them to specification.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the first and reverse gear from the output shaft.
2. Clamp the output shaft, front end facing upward, in a soft-jawed vise. Remove the fourth and fifth-speed synchronizer assembly from the shaft. Remove the snap ring retaining the fourth-speed gear and remove the shift hub sleeve and fourth-speed gear.
3. Remove the third-speed gear snap ring and lift off the locating washer and gear.
4. Lift off the second and third-speed synchronizer assembly.

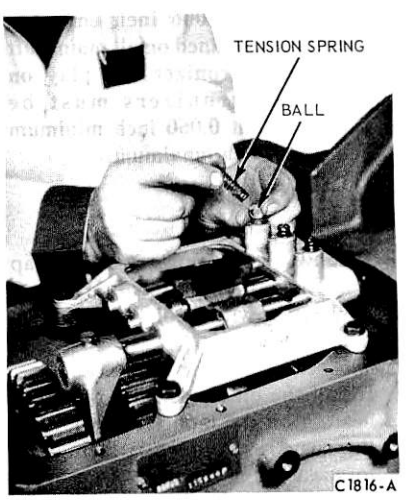

FIG. 5 Installing Shift Rod Locking Springs and Balls

5. Remove the snap ring retaining the second and third-speed gear shift hub sleeve and lift the sleeve off the shaft.
6. Remove the second-speed gear snap ring and remove the locating washer and gear.

Assembly

1. Install the output shaft, forward end up, in a soft-jawed vise.
2. Install the second-speed gear lower snap ring and locating washer on the output shaft. Install the second-speed gear on the shaft with the clutching teeth facing upward. Install the upper snap ring. **While pressing downward on the second speed gear to compress lower helical snap ring, check the gap between the second gear and the upper snap ring. This gap must be a minimum of 0.006 inch.**
3. Install the second and third-speed shift hub and snap ring.
4. Install the second and third-speed synchronizer assembly on the shaft.
5. Install the third-speed gear on the shaft with the clutching teeth facing downward. Install the third-speed gear locating washer and snap ring.
6. Install the fourth-speed gear with the clutching teeth up.
7. Install the bottom cone of the fourth and fifth-speed synchronizer over the cluthcing teeth of the fourth-speed gear.
8. Install the fourth and fifth-speed shift sleeve hub. **Be sure the chamfered side is facing down. Install the snap ring.**
9. Install the fourth and fifth-speed synchronizer on the shift hub sleeve (Fig. 6).
10. Reverse the output shaft and install the first and reverse gear with the shift fork groove facing down. **A minimum of 0.006 inch end play must be maintained on all mainshaft gears. Synchronizer end play on both synchronizers must be maintained at 0.060 inch minimum and 0.160 inch maximum.**

INPUT SHAFT

Disassembly

1. Remove the bearing retaining snap ring from the input shaft. Remove the bearing with Tool T53T-7065-A (Fig. 7).

Assembly

1. Install the oil slinger and press the bearing on the input shaft. Be sure the snap ring groove is facing the forward end of the shaft. **To prevent damage to the bearing, apply pressure on the inner race of the bearing only.**
2. Install the bearing snap ring.

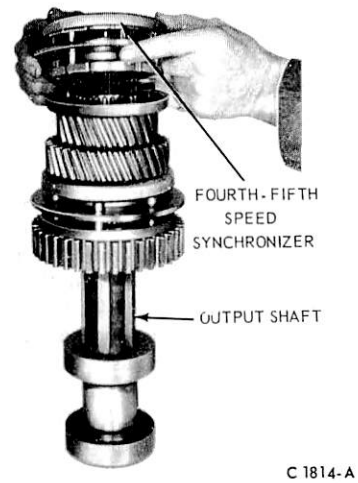

FIG. 6 Installing Fourth-Fifth Speed Synchronizer

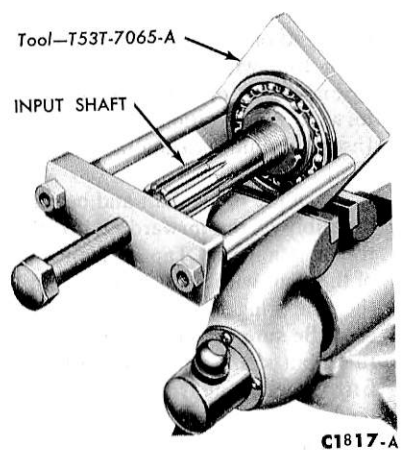

FIG. 7 Removing Input Shaft Bearing

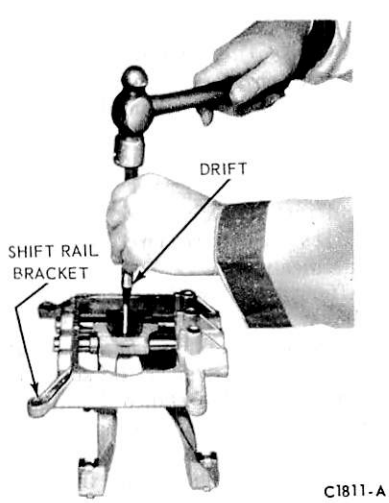

FIG. 8 Removing shift Fork Roll Pin

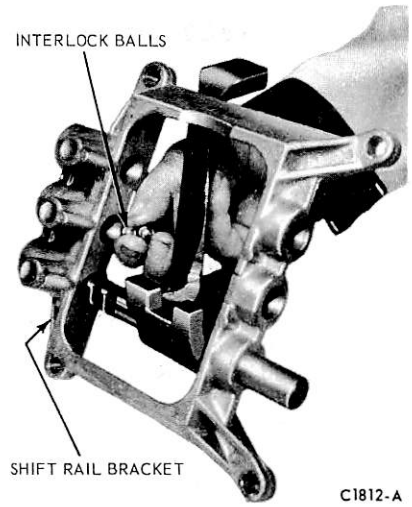

FIG. 9 Installing Shift Rod Interlock Balls

COUNTERSHAFT

Disassembly

1. Remove the snap ring at the forward end of the countershaft (Fig. 1).
2. Place the countershaft assembly in a hydraulic press, and press the drive gear off the shaft.
3. Remove the key from the shaft and press the fourth-speed gear off the shaft. Remove the remaining key.

Assembly

1. Install the fourth-speed gear Woodruff key in the slot on the shaft. Position the fourth speed gear on the shaft with the long hub facing toward the front.
2. Install the countershaft main drive gear key in the keyway in the shaft. Install the countershaft drive gear on the shaft with the long hub facing toward the rear. Install the snap ring on the countershaft.

GEAR SHIFT HOUSING

Disassembly

It is not necessary to disassemble the gear shift housing assembly (Fig. 10) to determine if parts are worn. Note the condition of the shifter fork shafts and forks by a visual inspection. If the forks are excessively worn, or if they bind when shifted into the various positions, disassemble the gear shift housing assembly to make repairs. Check the interlocking system.

1. Remove the first and reverse shift lug lock screw and slide the shift fork, rod and lug from the shift rod support.
2. Using a small drift remove the second and third-shift fork roll pin and slide the shift rod out of the support assembly (Fig. 8). **Do not lose the interlock pin or spacer.**
3. Remove the fourth and fifth-shift

fork roll pin with a small drift. Remove the shift rod and fork from the support assembly.

Assembly

1. Slide the fourth and fifth-shift shaft through the shift support and into the fourth and fifth-shift fork. Install the roll pin and move the rod to the neutral position.
2. Install two interlock balls between the shift shaft bores (Fig. 9).
3. Slide the second and third-shift rod through the shift support. Install the spacer and interlock pin in the shift rod.
4. Install the second and third-shift fork roll pin and move the rod to the neutral position.
5. Install two interlock balls between the second and third and first and reverse shift rod bores.
6. Install the first and reverse rod in the support and in the shift lug.
7. Install the first and reverse lug lock screw and lock wire.

DESCRIPTION

TRANSMISSION

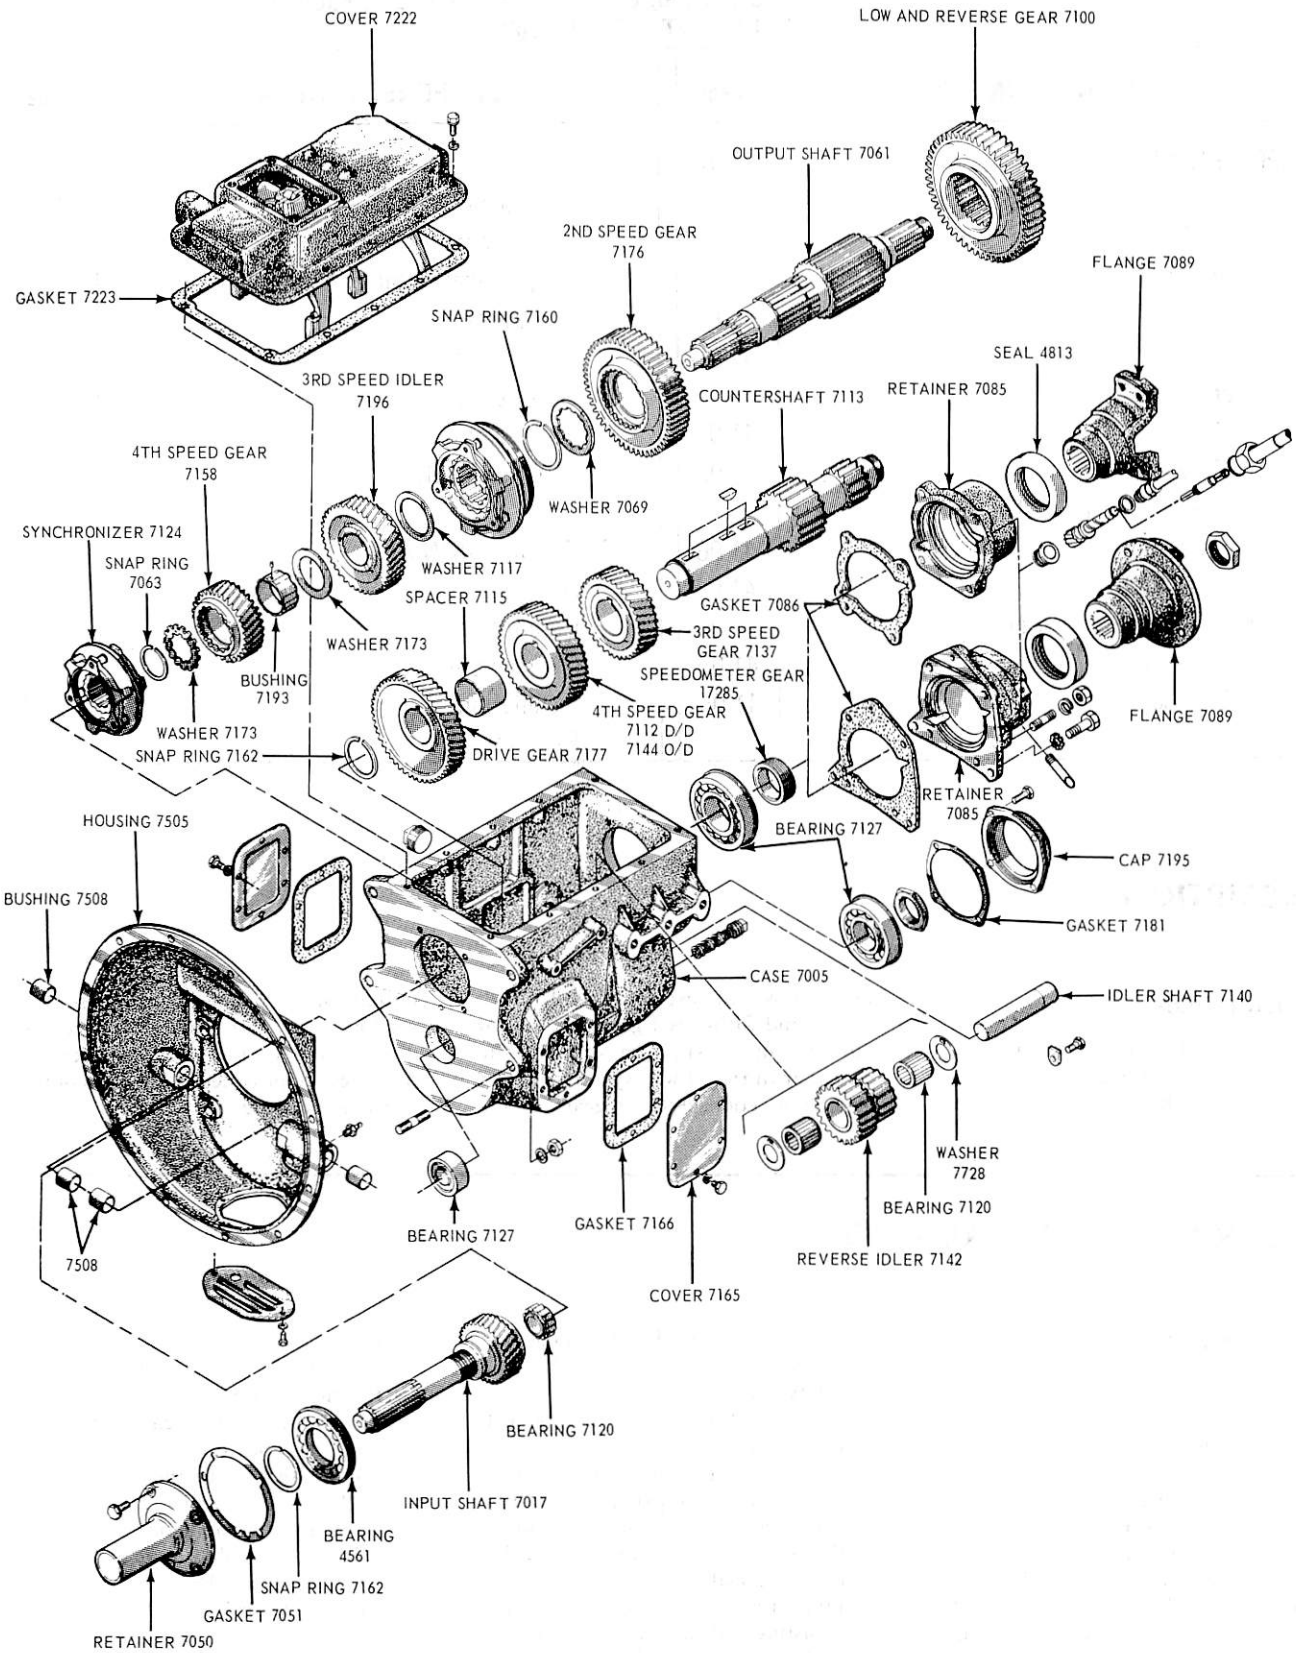
The Clark 380 Series transmissions are of the synchromesh type, with synchronized shifting in all speeds except low and reverse. Second, third, fourth and fifth-speed gears are helical cut and in constant mesh with the countershaft. Two synchronizer assemblies connect these gears to the output shaft. The low and reverse-speed gear is a spur cut gear, splined to the output shaft. Two power take-off openings are provided in the sides of the transmission case.

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate. Remove the gear shift lever housing and disconnect the parking brake lever. Cover the case opening.
2. On C-Series units, shift the transmission into neutral, release the lock and tilt the cab forward. Remove the rear cross-shaft housing bolts. Tie the housing so that it does not fall. If necessary to provide room for removal of the transmission, raise the rear of the truck and install safety stands.
3. Drain the transmission. Disconnect the drive shaft (or the coupling shaft) at the parking brake drum. If the truck is equipped with a coupling shaft support, disconnect the support bracket and remove the coupling shaft.
4. Disconnect the parking brake adjusting rod and the speedometer cable. Remove the driven gear and its bearing (Fig. 1).
5. Remove the dust cover from the bottom of the clutch housing. Position a transmission jack under the transmission. Remove the top nuts, the bottom bolts and lock washers that secure the transmission to the clutch housing.
6. Move the transmission to the rear until the input shaft splines clear the clutch housing. Be careful that the clutch release bearing and hub do not drop out of the release lever fork. Lower the transmission to the floor.



C 2697-A

FIG. 1 Disassembled View Clark 380 Series Transmission

Installation

1. Place the transmission on a transmission jack. Raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. On C-Series units, position the cross-shaft housing on the transmission case adapter and install the mounting bolts. Torque the bolts to specification.
3. Install the lock washers, the top nuts and the bottom bolts. Torque to specifications. Install the dust cover on the bottom of the clutch housing. Position the speedometer driven gear bearing and the gear. Connect the speedometer cable.
4. Connect the parking brake adjusting rod.
5. Install the coupling shaft in the support bracket and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
6. Install the shift lever housing. When positioning the gear shift lever housing, always lower it down onto the gear shift housing. Torque the gate plunger retainer to specification.
7. Lower the truck to the floor. Install the floor plate and the floor mat. Fill the transmission with the correct amount of the specified lubricant. Adjust the remote control shift linkage.
8. Check the clutch pedal free travel and adjust it if necessary.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Remove the gear shift housing assembly.
2. Shifting by hand, engage the transmission into two speeds at the same time.
3. Remove the output flange nut cotter pin.
4. Remove the nut.
5. Remove the parking brake band assembly.
6. Remove the brake drum and flange assembly.
7. Remove the output shaft and countershaft rear bearing caps and gaskets.
8. While the transmission is still locked in two speeds, remove the countershaft rear bearing attaching nut.
9. Remove the input shaft bearing cap and gasket.
10. Remove the input shaft and bearing assembly from the front of the case. **Proceed with caution to avoid dropping the pilot bearing from the pocket of the drive gear if it remains with the gear. If not in the pocket of the gear, remove it from the end of the output shaft pilot.**
11. Remove the speedometer drive gear and the speedometer drive gear spacer from the output shaft. Move the output shaft assembly toward the rear of the case far enough that the rear bearing clears the case. Using a suitable puller, remove the bearing from the end of the shaft.
12. The forward end of the output shaft can now be tilted upward to clear the front of the case and the entire assembly removed.
13. Remove the screw and lock washer holding the reverse idler shaft lock plate at the rear of the case and remove the lock.
14. Using a suitable puller in the slot in the end of the reverse idler shaft, pull the shaft from the case.
15. Lift the reverse idler gear from the case.
16. Remove the two reverse idler bearings and bearing spacer from the hub of the reverse idler gear.
17. Push the countershaft toward the rear of the transmission case far enough that the rear countershaft bearing can be removed from the countershaft.
18. The countershaft assembly can now be removed by tilting the forward end upward in a manner similar to that used in removing the main shaft.
19. If countershaft front or pilot bearing is to be replaced, remove clutch housing from transmission.
20. Press pilot bearing from transmission case. **Do not hammer or drive out bearing as damage or distortion to the bore in case will result.**

Assembly

1. If countershaft front bearing is to be replaced, coat outer diameter of pilot bearing with a suitable sealer.
2. From clutch housing end of case with open end of bearing toward rear of transmission, press the bearing 0.007 inch below front face of case.
3. Tip the rear end of the countershaft down and lower it into the case, running the rear of the countershaft through the countershaft bearing opening in the rear of the case far enough that the front of the countershaft may be lowered into position. Push the countershaft forward into position.
4. Install the countershaft rear bearing. Be sure that the snap ring is in position in the groove of the outer race of the countershaft rear bearing and press the bearing into position on the shaft with the snap ring toward the rear.
5. Insert the two roller bearings and the spacer into the hub of the reverse idler gear and position it in the case. The gear with the chamfered teeth should be toward the rear of the case.
6. Insert the reverse idler shaft through the hole in the rear of the case, through the reverse gear and into the forward support boss. Shaft should be driven inward until the forward face of the slot in the shaft is flush with the rear face of the case and slot lined up to permit installation of a locking plate.
7. Install the locking plate in position in the slot in the end of the shaft and secure with capscrew and lock washer.
8. Position the output shaft assembly in the transmission case by tilting the rear end of the assembly down and lowering it into and through the opening in the rear of the case. Lower the front end in line with the pilot bearing opening and move the output shaft assembly forward into position. Let the shaft rest in this position until assembly is completed.
9. Assemble the output shaft rear bearing over the end of the output shaft with snap ring in outer race facing toward the rear.

10. Install pilot bearing on the output shaft.
11. Install the input shaft and bearing assembly in the case so that the input shaft gear engages and meshes with the countershaft gear and the output shaft and pilot bearing are seated in the input shaft bore. If a new pilot bearing is used, it will be in a plastic sleeve. Stand the drive gear on end. Set the bearing and sleeve over the bearing pocket in the drive gear. Slide the bearing rollers and cage from the plastic sleeve into the bearing pocket. **Important—When a new bearing is used, always install a new bearing race on the mainshaft. If the old pilot bearing is used, set the rollers in the bearing cage and hold them in place with a rubber band. Slide the bearing rollers and the cage from the rubber band into the bearing pocket.**
12. Install the input shaft bearing cap and gasket. Be sure the oil return hole in the cap is lined up with the oil return hole in the case. This passage must be open and clear.
13. Lock gears into two speeds at one time and install the countershaft rear bearing attaching nut. Torque the nut to specification and stake in position with a punch.
14. Install the countershaft rear bearing cap and gasket.
15. Install the speedometer drive gear spacer and speedometer drive gear on the output shaft.
16. Install the output shaft rear bearing cap assembly and gasket.
17. Install the parking brake drum and companion flange assembly.
18. Install the companion flange nut. Tighten the nut to specification. Install a new cotter pin to lock this nut into position.
19. Move all gears to neutral and assemble the gear shift housing and gasket to the transmission case, making sure the shift forks engage slots of the gears.
20. Assemble the gasket, gear shift lever and tower assembly to shift bar housing.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the first and reverse sliding gear and the fourth and fifth synchronizer assembly from the output shaft.
2. Place the balance of the assembly in a vise using copper or lead jaws so as not to damage splines. This assembly should be positioned with the front end upwards.
3. Spread the snap ring holding the fourth-speed gear and remove it from the shaft.
4. Remove the fourth-speed gear and washer from the shaft.
5. Remove the assembly from the vise and with the front end pointed downward, tap it lightly on a block of wood, allowing the weight of the third-speed gear to force the fourth-speed gear bushing off of the output shaft. After this sleeve has loosened, remove it from shaft along with the fourth-speed gear locating washer. When the sleeve is removed, the locating pin will come off with it. Care should be exercised not to lose this pin.
6. The third-speed loose gear may now be removed from the front end of the shaft.
7. Remove second and third-speed synchronizer assembly.
8. Remove second gear retaining ring and washer.
9. Remove second-speed constant mesh gear.
10. Remove second gear bushing sleeve and locating washer from shaft.

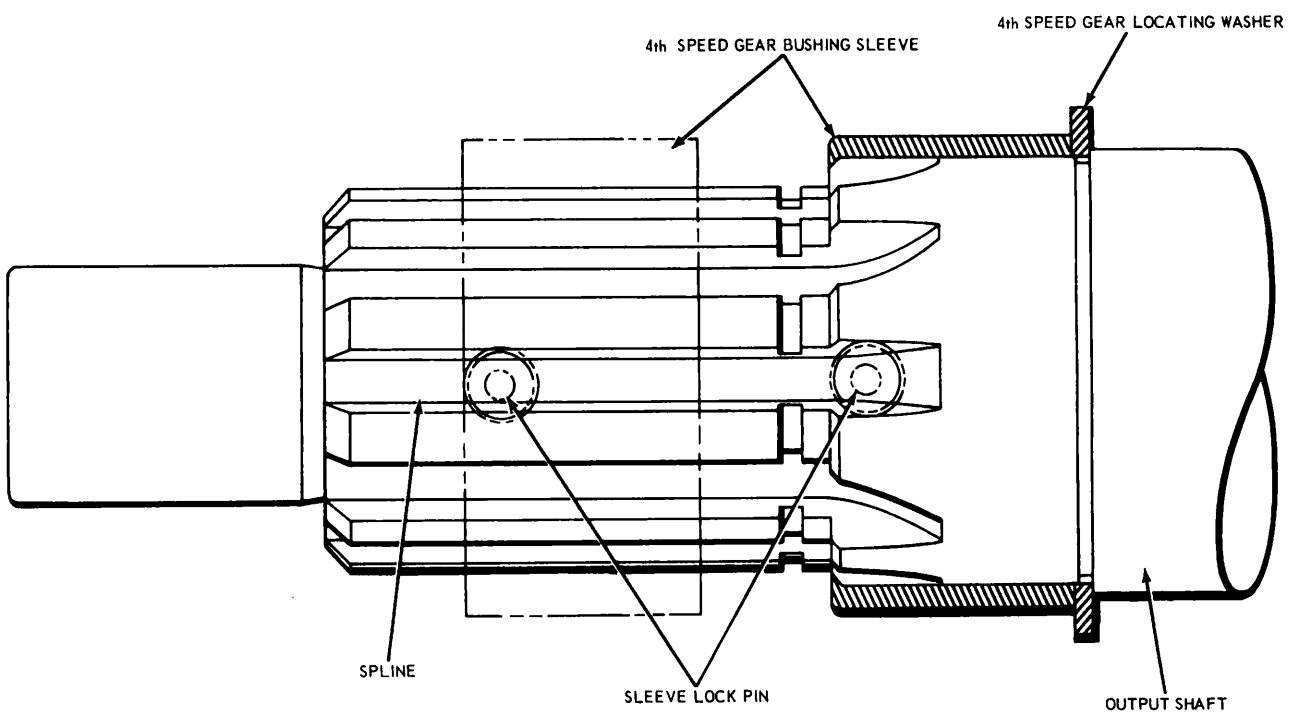


FIG. 2 Installing Bushing Sleeve

Assembly

1. Clamp the output shaft in a soft-jawed vise with the front end up.
2. Drop the second gear locating washer into position over the shaft.
3. With lockpin in place in the bushing sleeve, install the bushing sleeve on the shaft with the lockpin toward the upper end (Fig. 2).
4. To be sure of a properly tight stack-up between the second-speed locating washer, second-speed bushing sleeve, second-speed retaining washer and snap ring, the following procedure should be used. Before the second-speed gear is installed on the bushing sleeve, place a retaining washer on the shaft and hold it down tight against the bushing sleeve. Holding the snap ring parallel to the retaining washer, slip the snap ring into the snap ring groove in the mainshaft (Fig. 3). Select variable thickness washers until a washer is selected that will give 0.004 inch maximum snap ring looseness. Remove the selected washer and install the gear over the bushing sleeve. Place the selected washer in position and install snap ring on shaft so that it is locked securely in the groove. End play on second gear must be a minimum of 0.006 inch.
5. Place the second and third-speed synchronizer on the splines of the shaft and drop it into position.
6. Drop the third gear thrust washer into position over shaft.
7. Place the third-speed gear on the shaft with toothed hub downward.
8. Drop the fourth-speed gear locating washer into position over the shaft.
9. With the lockpin in place in the bushing sleeve, install the bushing sleeve on the shaft with the lockpin toward the upper end (Fig. 2).
10. To be sure of a tight stack-up between the fourth-speed locating washer, fourth-speed bushing sleeve, fourth-speed retaining washer and snap ring, follow the procedure given in step 4 above, selecting a retaining washer that will give 0.004 inch maximum snap ring looseness (Fig. 3). Mainshaft gears must maintain minimum gear end play as follows:
    2nd—0.006 inch
    3rd—0.009 inch
    4th—0.006 inch
11. Remove the assembly from the vise and install the sliding gears on the shaft as follows: Fourth and fifth-speed synchronizer hub with the large end toward the rear. First and reverse gear with the fork slot toward the front.

COUNTERSHAFT

Disassembly

1. Remove the snap ring from the front end of the countershaft.
2. Using an arbor press or suitable gear puller, remove the countershaft drive gear spacer, fourth-speed gear and third-speed gear.
3. Remove the gear keys from the shaft.

Assembly

1. Install a Woodruff key in each key slot on the countershaft except the drive gear.
2. Press the third-speed gear onto the shaft with the long hub toward the rear.
3. Press the fourth-speed gear onto the shaft with the long hub toward the rear.
4. Install drive gear spacer and drive gear key.
5. Press the countershaft drive gear onto the shaft with the long hub toward the rear.
6. Install the retaining ring.

INPUT SHAFT AND BEARING

Disassembly

1. Place input shaft gear in vise using copper or lead jaws so as not to damage teeth.
2. Remove the jam nut holding the bearing on the input shaft.
3. Using a suitable puller or an arbor press, remove the bearing from the input shaft.

Assembly

1. Assemble the bearing on the output shaft with the snap ring toward the pilot end of the gear.
2. Install the bearing attaching nut and torque it to specifications.
3. Stake the nut in position.

OUTPUT SHAFT REAR BEARING CAP

Disassembly

1. Press or drive out the oil seal. This should be done only if the oil seal needs replacement.

Assembly

1. Press new oil seal in bearing cap (lip of seal down toward transmission).

GEAR SHIFT HOUSING

Disassembly

1. Place the cover on a bench in an inverted position (Fig. 4) with the expansion plug opening facing upward.
2. Remove the expansion plugs from the forward openings in the cover.
3. Remove the lock wires from the shifter lugs and forks.
4. Shift all rails into neutral position.
5. Remove the lock screw from second and third shift fork and move the rail toward the rear of the cover so

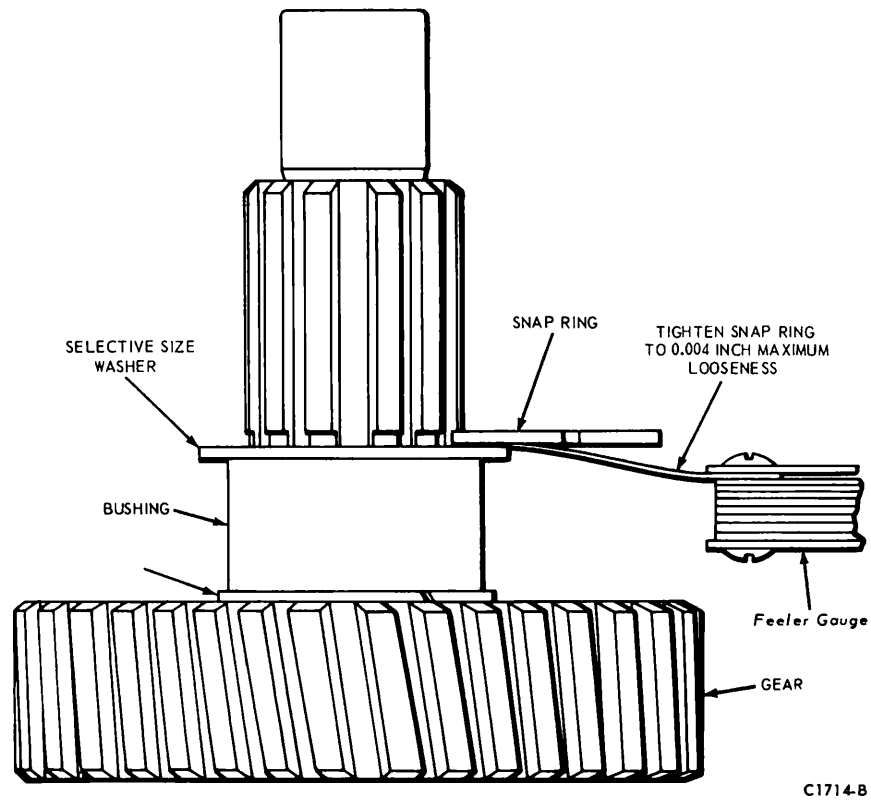

FIG. 3 Setting Second or Fourth-Speed Gear End Play

the lock screw can be removed from the lug.
6. Holding a thumb over the detent ball hole in the center rail support to prevent losing the ball, remove the rail, lug and fork from the cover.
7. Remove the lock screw from the fourth and fifth shift fork and move the rail toward rear of cover so the lock screw can be removed from the lug.
8. Holding a thumb over the detent ball hole to prevent loss of the ball, remove the fourth and fifth shift rail, fork and lug from the cover.
9. Remove the lock screw from the first and reverse shift fork.
10. Holding a thumb over the detent ball hole in center rail support, remove the shift fork and rail from the cover.
11. Remove mesh lock springs and the four (4) interlock balls located in cross bore holes between first and reverse, fourth and fifth and second and third detent ball holes of center rail support.
12. Remove lock screw from first and reverse rocker lug, then move the rail toward the rear of the cover so that the lock screw can be removed from the first and reverse lug.
13. The rocker arm may be lifted from the pivot pin.

Assembly

Install fourth and fifth shift rail and fork in following manner:
1. Push rail through forward opening of cover.
2. Install two (2) interlock balls between first and reverse and fourth and fifth rails.
3. Place detent ball spring in position in well of forward rail support.
4. Place detent ball in position on spring.
5. Using suitable tool, compress spring and ball in such a manner as to pass between guide fingers of first and reverse rocker lug if fingers are aligned.
6. Slide fourth and fifth shift fork on rail with offset for lock screw toward rear of cover.
7. Install lock screw in fork and wire securely.
8. Shift into neutral position.

Install second and third shift rail and fork in the following manner:
1. Push rail through forward opening in cover.
2. Install two (2) interlock balls between second and third and fourth and fifth detent ball holes of forward rail support.
3. Place the detent ball spring in position in the well of the rail support.
4. Place the detent ball in position on the spring.
5. Using suitable tool, compress spring and ball in such a manner as to allow rail to pass through support.
6. Slide second and third shift fork onto rail with offset for lock screw toward repairman.
7. Install lock screw in fork and wire securely.
8. Shift into neutral position.
9. Install the expansion plugs in the forward openings.

Assemble first and reverse shift fork and rail in the following manner:
1. Install detent ball lock spring and ball in well of first and reverse shift fork (Fig. 4).
2. Using a suitable tool, compress the ball and spring so that rail may pass through fork.
3. Push rail through rear opening of cover.
4. Holding fork in position on rocker arm and with offset to the rear of the cover, push rail through fork and into rail support.
5. Install the lock screw in the rail support and rail, then wire securely. Check assembly of cover by shifting in and out of speeds. Then shift into fifth-speed and attempt to shift into first, reverse, second or third at the same time. This provides a check on the proper assembly of interlock balls and pin. Shift lever should not shift into more than one speed at a time.
6. Return the rail to neutral position.

GEAR SHIFT LEVER AND TOWER

Disassembly
1. Remove the gear shift knob and dust cover.
2. Remove the shift lever, support spring and washer.
3. The shift lever may now be removed from the shift tower.

Assembly
1. Place shift lever in shift tower.
2. Position shift lever to transmission case. Replace washer and support spring.
3. Replace dust cover and gear shift knob.

REVERSE LUG ASSEMBLY

Disassembly
1. Remove the cotter key from the end of the plunger.
2. Remove the nut from the end of the plunger.
3. Spring and plunger may not be removed from well in lug.

Assembly
1. Replace plunger and spring in well in lug.
2. Replace nut on end of plunger.
3. Install cotter key.

DESCRIPTION

TRANSMISSION

The Model 5000 extra heavy-duty five-speed transmission (Fig. 1) is a manually shifted, synchromesh, helical gear type. Fifth forward speed is direct drive. The main drive gear bearing is a single row ball type. The mainshaft is supported by straight roller pilot bearings at the front and a single row ball bearing at the rear. The countershaft is mounted on a straight roller bearing at the front and a single row ball bearing at the rear. The reverse idler gear rotates on two straight roller bearing. Power take-off openings are provided on the right and left sides of the transmission case.

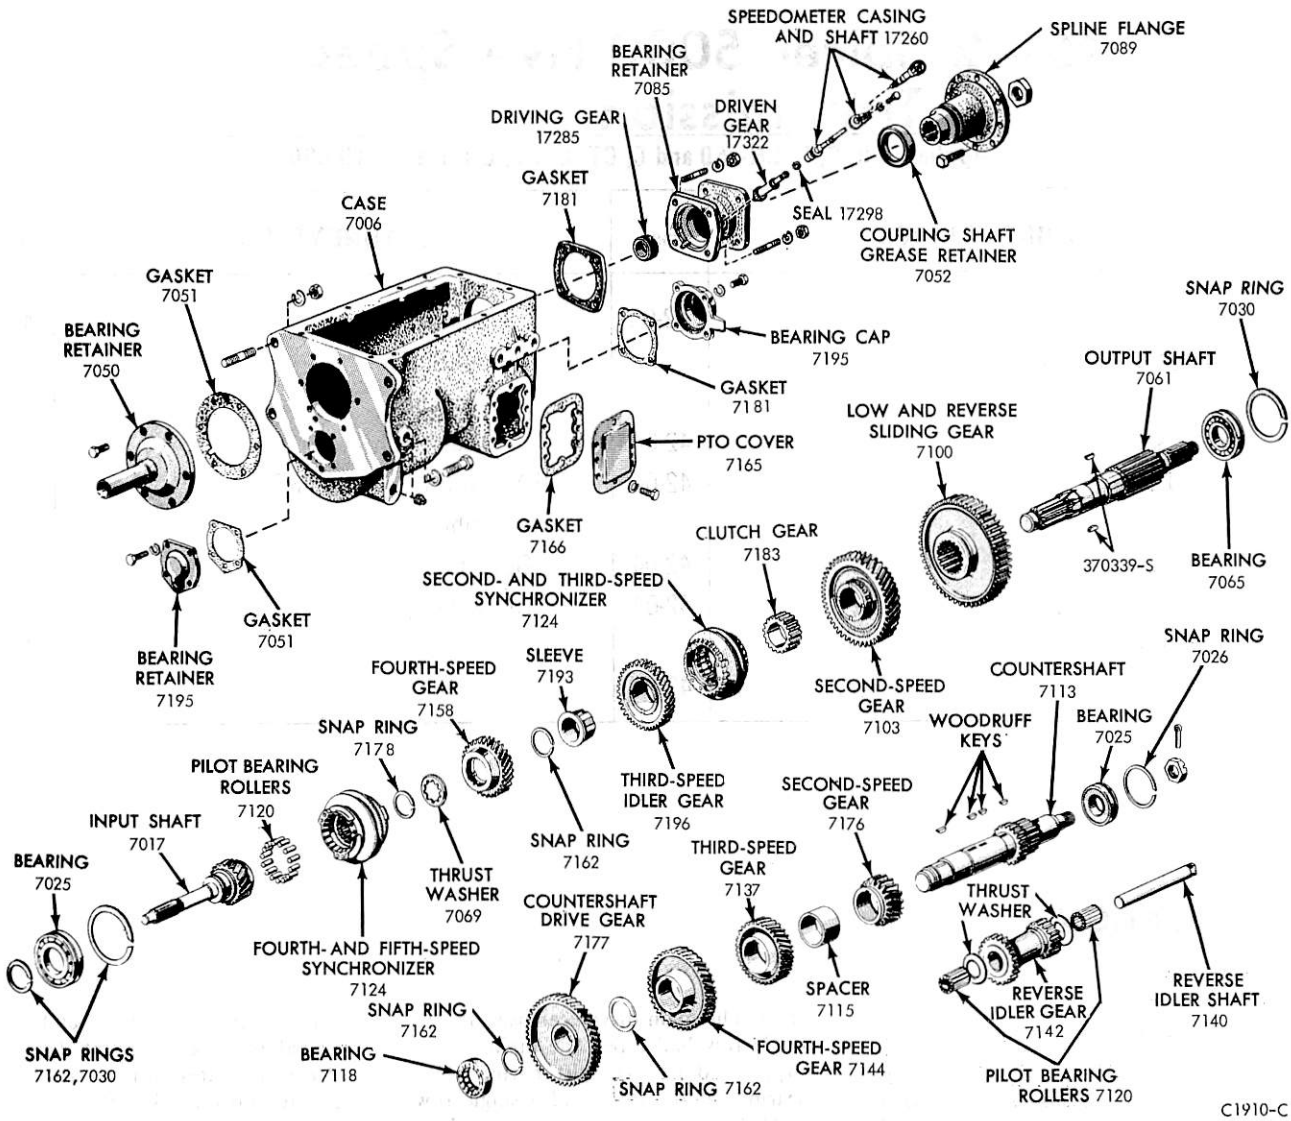

FIG. 1 Spicer Model 5000 Transmission—Disassembled

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate.

Remove the gear shift lever housing and disconnect the parking brake lever. Cover the case opening.

2. On C-Series units, shift the transmission into neutral, release the lock and tilt cab forward. Remove the rear cross-shaft housing bolts. Tie the housing so that it does not fall. If necessary to provide room for removal of the transmission, raise the rear of the truck and install safety stands.
3. Drain the transmission. Disconnect the drive shaft (or the coupling shaft) at the parking brake drum. If the truck is equipped with a coupling shaft support, disconnect the support bracket and remove the coupling shaft.
4. Disconnect the parking brake adjusting rod and the speedometer cable. Remove the driven gear and its bearing (Fig. 1).
5. Remove the dust cover from the bottom of the clutch housing. Position a transmission jack under the transmission. Remove the top nuts and the bottom bolts and lock washers that secure the transmission to the clutch housing.
6. Move the transmission to the rear until the input shaft splines clear the clutch housing. Be careful that the clutch release bearing and hub do not drop out of the release lever fork. Lower the transmission to the floor.

Installation

1. Place the transmission on a transmission jack. Raise the transmission until the input shaft splines are aligned with the clutch disc splines. The clutch release bearing and hub must be properly positioned in the release lever fork. Slide the transmission forward until it is positioned to the clutch housing.
2. On C-Series units, position the cross-shaft housing on the transmission case adapter and install the mounting bolts. Torque the bolts to specification.
3. Install the lock washers, the top nuts and the bottom bolts. Torque the bolts and nuts to specifications. Install the dust cover on the bottom of the clutch housing. Position the speedometer driven gear bearing and the gear. Connect the speedometer cable.
4. Connect the parking brake adjusting rod.
5. Install the coupling shaft in the support bracket. Connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
6. Install the shift lever housing. When positioning the gear shift lever housing, always lower it straight down onto the gear shift housing. Torque the gate plunger retainer to specification.
7. Lower the truck to the floor. Install the floor plate and the floor mat. Fill the transmission with the correct amount of the specified lubricant. Adjust the remote control shift linkage.
8. Check the clutch pedal free travel and adjust it if necessary.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Remove the gear shift housing from the transmission case. Lift the housing straight up. Remove the detent balls from the housing and shift the transmission into two gears.
2. Remove the brake drum and spline flange.
3. Remove the brake shoe assembly. Remove the output shaft bearing retainer, speedometer driving gear and spacer (Fig. 1).
4. Remove the countershaft rear bearing retainer and gasket. Remove the countershaft nut.
5. Remove the left-side power take-off cover.
6. Remove the input shaft bearing retainer and gasket from the case. Using a soft drift, drive the input shaft out of the transmission case bore until the front bearing is exposed. Remove the bearing from the bore and slide the input shaft out of the case. Remove the pilot rollers from the drive gear.
7. With a hardwood or fiber block placed against the front side of the second-speed gear, drive the output shaft assembly rearward until the output shaft bearing clears the case. **Be careful not to butt the secondspeed gear against the countershaft reverse gear.** Remove the bearing from the output shaft (Fig. 2).
8. Slide the first-speed gear off the output shaft as the shaft assembly is removed from the case.
9. Remove the countershaft rear bearing outer race snap ring. Remove the bearing, using a standard puller.
10. Work the countershaft toward the rear of the case until it clears the front bearing and lift the assembly out of the case.
11. Remove the countershaft front bearing retainer and retainer gasket. Tap the bearing out of the front of the case.
12. Remove the reverse idler gear and remove the bearings from the gear bores.
13. Remove any of the 14 output shaft pilot rollers which may have dropped into the case.

Assembly

Coat all parts with transmission lubricant to prevent scoring when the transmission is first operated.

1. Tap the countershaft front bearing into the case. Place a new gasket on the bearing retainer and install it. Line up the oil return holes in the retainer, gasket and case. Torque the retaining bolts to specification.
2. Place the assembled countershaft in the transmission case. Start the shaft in the front bearing.
3. Drive the countershaft rear bearing onto the countershaft and into the case with Tool T53T-7065-B.
4. Place the bearings in the reverse idler gear and install the gear in the case. Drive the idler gear shaftt into position and install the power takeoff cover.
5. Tap the input shaft and bearing into the case. Place the output shaft pilot roller bearing rollers in the input shaft.
6. Install the input shaft bearing retainer **without a gasket** and tighten the bolts to bottom the retainer on the bearing outer race snap ring. With a feeler gauge, check the clearance between he bearing retainer gasket surface and the case.
7. Use a gasket pack that will seal between the bearing retainer and case. Prevent any end play at the bearing outer race snap ring. Install the bearing retainer with the oil drain-hole in line with the gasket and case holes. Torque the retainer bolts to specification.
8. Install the low and reverse gear on the output shaft and position the assembly in the case. Drive the output shaft bearing into position with Tool T57L-600-A.
9. Shift the transmission into two gears. Install the countershaft nut and torque to specification. Install the countershaft rear bearing retainer. Torque the retainer bolts to specification.
10. Install a new oil seal in the output shaft bearing retainer. Place the spacer and speedometer driving gear on the output shaft and install the bearing retainer. Torque the bolts to specification.
11. Install the parking brake shoe assembly.
12. Install the brake drum and the spline flange. Torque the output shaft nut to specification.
13. Shift the transmission and gear shift

housing into neutral and install the gear shift housing. Torque the bolts to specification.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the fourth and fifth-speed synchronizer assembly, snap ring and thrust washer at the front of the fourth-speed gear (Fig. 1). Remove the gear.
2. Remove the snap ring at the front of the third-speed gear sleeve. Bounce the front of the output shaft on a hardwood block to remove the second and third-speed synchronizer.
3. Place the output shaft in a press, with the rearward side of the second-speed gear resting on the press bed. press the output shaft out of the second and third-speed synchronizer clutch gear and second-speed gear.

Assembly

1. Place the second-speed gear onto the output shaft with the clutch teeth toward the front.
2. Install the two Woodruff keys in the output shaft. Press the second and third-speed synchronizer clutch gear onto the output shaft.
3. Place the second and third-speed synchronizer and third-speed gear and gear sleeve on the output shaft. Press the sleeve onto the shaft until it bottoms on the synchronizer clutch gear. **The third-speed gear sleeve slots must line up with the Woodruff keys in the output shaft.**
4. Remove the assembly from the press and install the snap ring at the front of the third-speed gear sleeve.
5. Install the fourth-speed gear, thrust washer and snap ring on the output shaft. Install the fourth and fifth-speed synchronizer on the output shaft.

COUNTERSHAFT

Disassembly

If the countershaft or a countershaft gear is to be replaced, remove the snap rings and press the gears off, one at a time. To remove the second-speed gear, use the tool shown in Fig. 3.

Assembly

Press the gears and the spacer onto the shaft, one at a time, and install the snap rings (Fig. 1). **Install the Woodruff keys one at a time with their respective gears.**

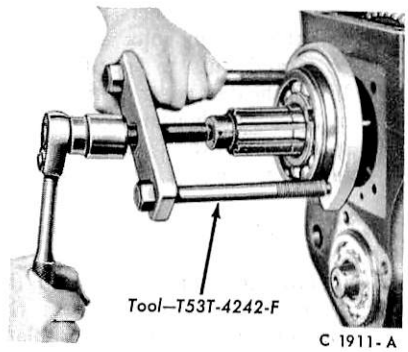

FIG. 2 Removing Output Shaft Bearing

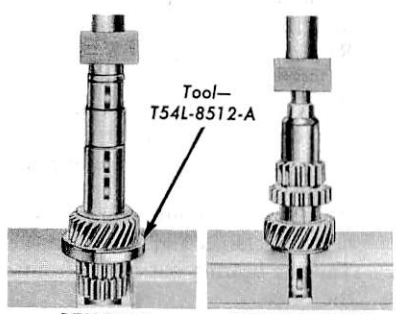

FIG. 3 Removing and Installing Second-Speed Gear

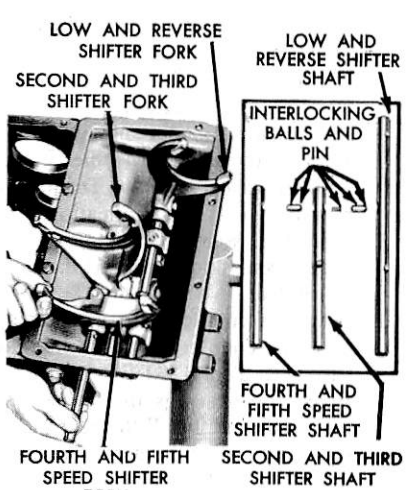

FIG. 4 Gear Shift Housing

INPUT SHAFT

Disassembly

Remove the input shaft bearing only for replacement. Remove the retaining snap ring and press the bearing off the shaft, using Tool T53T-4242-F6.

Assembly

Press the input shaft bearing onto the shaft using Tool T57L-600-A.

GEARSHIFT HOUSING

Disassembly

1. Attach the gear shift housing to the transmission case as shown in Fig. 4. Cut the lock wire from the retaining screws in the shifter forks and gates.
2. Mark the shifter forks, shafts and gates for correct assembly. Shift the shafts into neutral. Drive out the housing plugs at the front of the shafts (Fig. 5).
3. Remove the fourth and fifth-speed fork retaining screw. Slide the shaft out of the front of the housing.
4. Remove the second and third-speed fork and shaft. Remove the interlocking pin from the shaft (Fig. 4).
5. Remove the low and reverse shifter shaft, fork and gate. Remove the interlocking pin and plungers from the housing.

Assembly

1. Place the low and reverse shifter gate and fork in the housing. Slide the shaft into the housing and through the gate and fork. Install the retaining screws in the gate and fork. Torque the screw to specification and secure with lock wire.
2. Install two plungers in the housing interlocking bore between the low and reverse and second and third shifter shaft bores. Install the interlock pin in the shaft and the second and third-speed fork in the housing. Slide the shaft into the housing and through the fork. Install the retaining screw and secure it with lock wire.
3. Install the interlocking pin and plunger in the housing interlocking bore between the second and third-speed and fourth and fifth-speed shifter shaft guides. Install the fourth and fifth-speed shaft and fork. Install the retaining screw and secure it with lock wire.
4. Check the operation of the interlocking system. Coat the outer edge of the housing plugs with sealer and install them. Remove the housing from the transmission case.

DESCRIPTION

TRANSMISSION

The Model 6000 five-speed transmission is a manually shifted, synchromesh, helical gear type. Fifth forward speed is direct drive. The main drive gear bearing is a single row ball type. The mainshaft is supported by straight roller pilot bearings at the front and a single row ball bearing at the rear. The reverse idler gear rotates on two straight roller bearings. A power take-off opening is provided on the right and left side of the transmission case.

ADJUSTMENTS

REAR MOUNT

1. With the transmission weight off the mounting studs, torque the upper retaining nuts to specifications, and install the cotter pins (Fig. 1).
2. Loosen the lower retaining nut and the lock nut as necessary so that the transmission rear end hangs freely.
3. Insert a feeler gauge (0.06 inch) between the lower retaining nut and its washer (Fig. 1). **Do not apply pressure to the engine or the transmission. If necessary, back up the lower retaining nut to the stud shoulder.**
4. Turn the lower retaining nut downward until there is slight pressure on the gauge.
5. Repeat steps 2, 3 and 4 for the other side of the support.
6. Torque the lock nuts to specification.

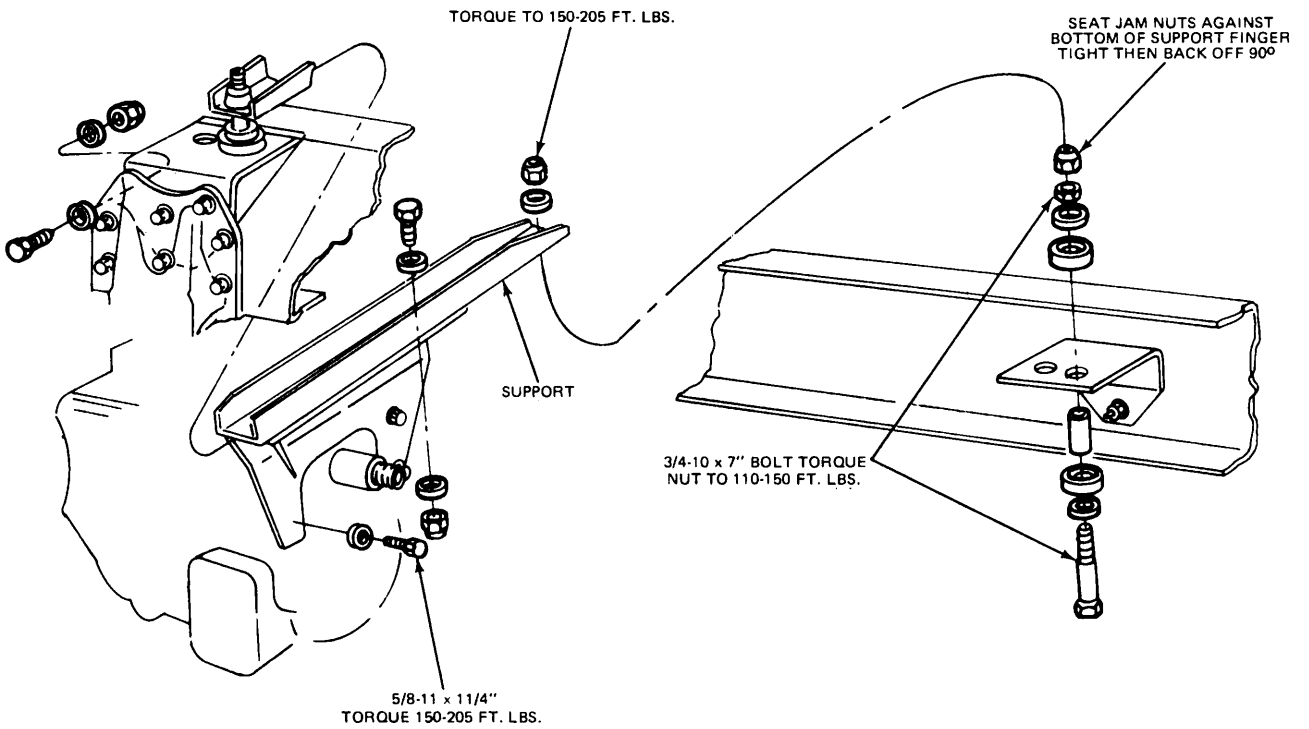

FIG. 1 Transmission Rear Support

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. On an L-Series truck, remove the floor mat and the floor plate.
2. Remove the low and reverse gate plunger (Fig. 2).
3. Remove the gear shift lever housing, and disconnect the parking brake lever if so equipped.
4. On a C-Series truck, shift the transmission into neutral, release the lock, and tilt the cab forward.
5. On a C or CT truck, remove the cross-shaft housing bolts and tie the housing out of the way.
6. Disconnect the drive shaft (or coupling shaft) at the transmission. If the truck is equipped with a coupling shaft support, disconnect the support bracket and remove the coupling shaft.
7. Disconnect the speedometer cable at the transmission. If the truck is equipped with a parking brake, remove the adjusting rod.
8. Disconnect the clutch linkage at the clutch release arm. If the truck is equipped with a slave cylinder, disconnect the slave cylinder return spring. Remove the slave cylinder mounting bolts and position the slave cylinder out of the way.
9. Position a jack under the transmission and raise the transmission slightly to relieve pressure at the side rail mounting brackets.
10. Remove the side rail bracket stud nuts, insulators, and reinforcements, and then remove each side rail bracket.
11. Remove the dust cover from the bottom of the clutch housing. After removing the clutch housing to engine attaching bolts, pull the transmission rearward to clear the input shaft.
12. Raise the truck to provide clearance in removing the transmission. Install safety stands, and then remove the transmission from under the truck.

Installation

1. Place the transmission on a transmission jack (or chain hoist) and position the transmission so that the input shaft splines are aligned with the clutch disc splines. The clutch release bearing must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. Install the clutch housing attaching bolts and torque them to specifications. Install the clutch housing dust cover.
3. Install the side rail brackets and torque the mounting bolts to specifications. Position the rear support studs, insulators, washers, and nuts as shown in Fig. 1 and adjust the studs.

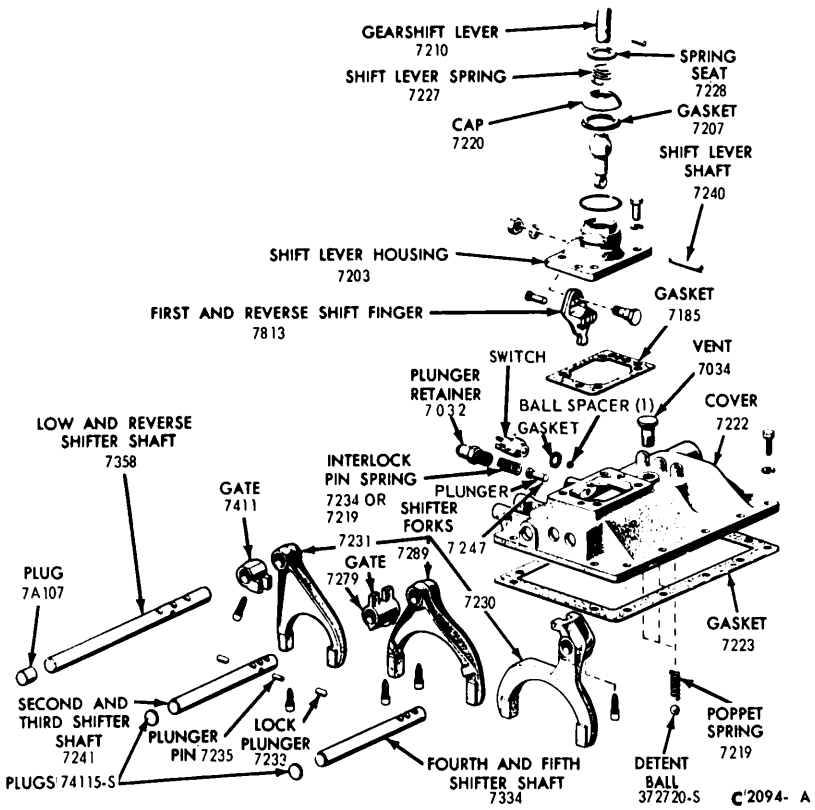

FIG. 2 Gear Shift Housing

4. Connect the clutch linkage to the clutch release arm. If the truck is equipped with a slave cylinder, install the slave cylinder and connect the slave cylinder return spring.
5. Connect the speedometer cable. If the truck is equipped with a parking brake, connect the adjusting rod.
6. Install the coupling shaft in the support bracket, and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
7. Install the shift lever housing. Install the low and reverse gate plunger in the shaft finger before installing the shift lever housing. **When positioning the gear shift lever housing, always lower it straight down onto the gear shift housing.** Torque the gate plunger retainer to specification.
8. Lower the truck to the floor, and install the floor plate and the floor mat. On a C-Series truck, lower the cab.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

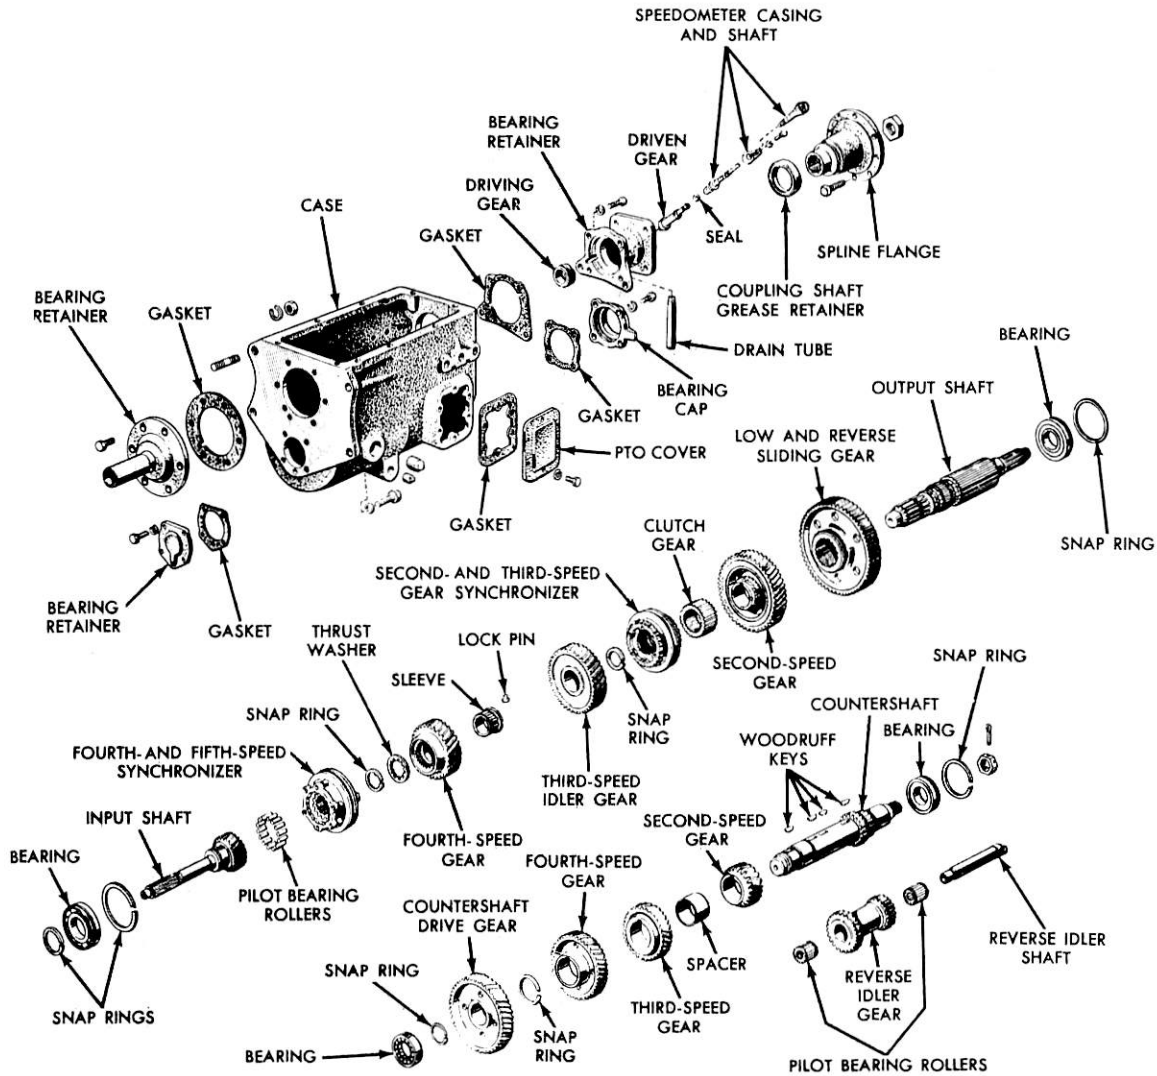
Disassembly

1. On a C-Series installation, remove the gear shift housing from the transmission case. **With the transmission in neutral, lift the housing straight up.**
2. Shift the transmission into 2 gears, and remove the parking brake drum and the spline flange.
3. Remove the brake shoe assembly.
4. Remove the input shaft bearing retainer and gasket. Tap the input shaft and bearing out through the front of the case.
5. Remove the output shaft pilot bearing from the pocket of the input shaft drive gear.
6. Remove the rear bearing retainers and gaskets from the output shaft and the countershaft. Remove the speedometer drive gear and spacer from the output shaft.
7. Remove the countershaft rear bearing retaining nut.
8. After removing the left power take-off cover, remove the reverse idler shaft.
9. Using a wood or fiber block against the front side of the second-speed gear (Fig. 3), drive the output shaft toward the rear until the rear bearing clears the case. Remove the bearing snap ring, and remove the bearing from the shaft.
10. Slide the low and reverse gear off the output shaft as the output shaft assembly is removed from the case.
11. Remove the countershaft rear bearing outer snap ring, and remove the bearing with Tool 7675-A.
12. Slide the countershaft toward the rear of the case until the shaft clears the front bearing, and lift the assembly out of the case.
13. Remove the countershaft front bearing retainer and gasket, and tap the bearing out of the case. Remove any of the 14 pilot rollers that might be in the transmission case, and take out the reverse idler gear. Remove the bearing from the idler gear.

Assembly

Coat all parts with transmission lubricant to prevent scoring when the transmission is first operated.

1. Tap the countershaft front bearing into the case. Position a new gasket on the front bearing retainer. Line up the oil return passages in the retainer, gasket, and case, and install the retainer. Torque the retainer bolts to specification.
2. Position the assembled countershaft in the transmission case, starting the shaft in the front bearing.
3. Drive the countershaft rear bearing onto the countershaft and into the case with Tool T53L-7065-B.
4. Place the bearings in the reverse idler gear, and position the gear in the case. Line up the flat surface on the rear end of the idler shaft with the position of the lock tang on the countershaft rear bearing retainer, and drive the idler shaft into position.



C 1932-A

FIG. 3 Transmission Disassembled

5. Position the output shaft assembly in the case.
6. With a wood block at the front of the shaft, drive the output shaft bearing into place, using Tool T57L-600-A.
7. Place the output shaft pilot rollers in the rear of the input shaft, holding the rollers in position with Lubriplate. The last roller must be inserted endways.
8. Install the input shaft and bearing.
9. Shift the transmission into 2 gears, install the countershaft rear bearing nut, and torque the nut to specification.
10. Install the countershaft rear bearing retainer, and torque the retainer bolts to specification.
11. Install a new oil seal in the output shaft rear bearing retainer and place the spacer and the speedometer drive gear on the shaft. Install the bearing retainer, and torque the retainer bolts to specification.
12. Install the input shaft bearing retainer **without a gasket,** and tighten the bolts to bottom the retainer on the bearing outer race snap ring. With a feeler gauge, check the clearance between the retainer gasket surface andthe case. This clearance should be 0.010-0.015 inch.
13. Select a gasket pack that will seal the oil between the retainer and the case and also prevent end play at the bearing outer race snap ring. Install the retainer, with the oil-drain hole in line with the gasket and case holes. Torque the retainer bolts to specification.
14. Position the brake shoe assembly, install the retaining bolts, and torque them to specification.
15. Install the U-joint flange, and torque the flange nut to specification.
16. **Install the parking brake drum and torque the mounting nuts to specification.**
17. Shift the transmission into neutral, and install the gear shift housing. Install the power take-off cover. Torque the mounting bolts to

specification. Fill the transmission with the specified lubricant.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the fourth and fifth-speed synchronizer assembly, and position the shaft (threaded end downward) in a soft-jawed vise. Remove the fourth-speed gear snap ring, the thrust washer, and the fourth-speed gear (Fig. 3).
2. Using the weight of the shaft and gears as a hammer, bounce the front end of the shaft on a hardwood block to force off the fourth-speed gear sleeve and the third-speed gear. Remove the second and third-speed gear synchronizer. Remove the snap ring, and slide the synchronizer clutch gear and the second-speed gear off the shaft.

The splines on the output shaft make use of machined notches (Fig. 4). The purpose of these notches is to prevent the transmission from walking out of gear under load conditions.

Assembly

Lubricate all free-running gear bearing bores and shaft surfaces.

1. Slide the second-speed gear and the synchronizer clutch gear onto the shaft. Install the clutch gear retaining snap ring.
2. Slide the second and third-speed synchronizer (with the longer hub to the rear) onto the shaft, and press on the third-speed gear. Install the lockpin.
3. Install the fourth-speed gear sleeve **(do not press the sleeve flange) and the fourth-speed gear. Position the thrust washer and install the snap ring. Slide the fourth and fifth-speed synchronizer onto the shaft. The brass synchronizer cones must mate with the gear cones.**
4. Position the low and reverse sliding gear on the shaft.

COUNTERSHAFT

Disassembly

If the countershaft or a countershaft gear is to be replaced, remove the snap rings and press off the gears (and the spacer, if necessary) one at a time. To remove the second-speed gear, use Tool T54L-8512-A. Remove the 3 Woodruff keys at the front of the shaft before pressing off the spacer and the second-speed gear (Fig. 3).

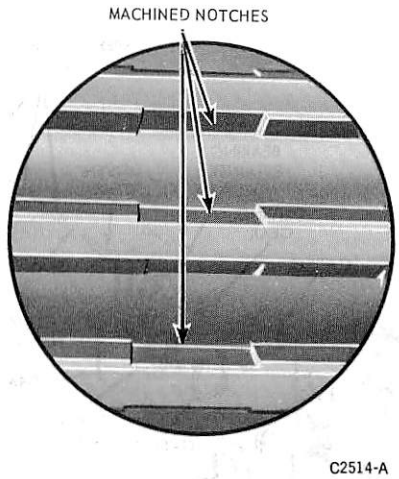


FIG. 4 Machined Notches in Output Shaft

Assembly

Press the gears and the spacer onto the shaft, one at a time, and install the snap rings (Fig. 3). **Install the Woodruff keys one at a time with their respective gears.**

INPUT SHAFT

Disassembly

The input shaft bearing should be removed only for replacement. Remove the bearing with the tool shown in Fig. 5.

Assembly

Press the input shaft bearing onto the shaft.

GEAR SHIFT HOUSING

Disassembly

1. Attach the gear shift housing to the transmission case, as shown in Fig. 6. Cut the lock wire from the retaining screws in the shifter forks and gates (Fig. 2).
2. Mark the shifter forks, shafts, and gates for correct assembly, shift the shafts into neutral. Drive out the expansion plugs at the front of the shafts.
3. Remove the fourth and fifth-speed fork retaining screw, and slide the shaft out of the front of the housing. **The shifter shaft detent balls and springs are installed in blind holes at the rear end of the shifter shafts (Fig. 6).**
4. Remove the second and third-speed fork and shaft. Remove the interlocking pin from the shaft.
5. Remove the low and reverse shifter shaft, fork, and gate. Remove the interlocking plungers from the housing.

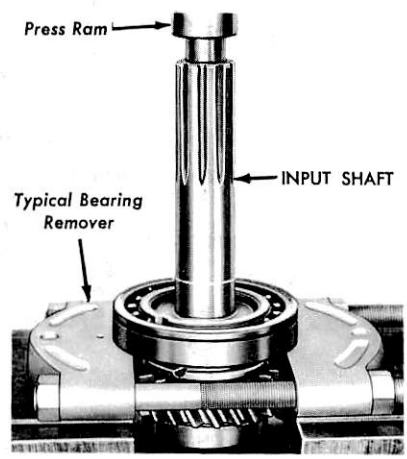

FIG. 5 Input Shaft Bearing Removal

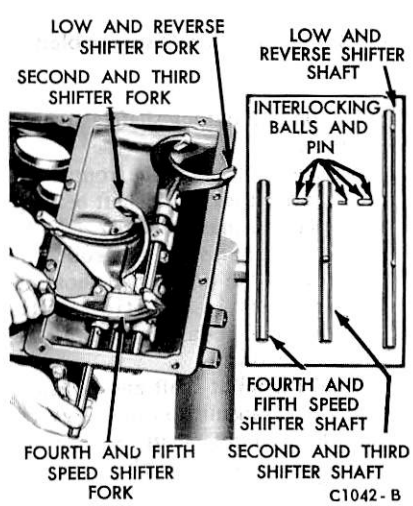

FIG. 6 Gear Shift Housing Mounting

Assembly

1. Position the low and reverse shifter gate and fork in the housing and through the gate and the fork.
2. Place the detent ball and spring in the housing. Push the ball down and slide the shaft past it. Install the retaining screws in the gate and the fork. Secure the screws with lock wire.
3. Install the interlocking pin and plunger in the housing interlocking bore between the low-and-reverse and the second and third shifter shaft bores. Install the interlock pin in the bore, and position the second and third-speed fork in the housing.
4. Slide the shaft into the housing and through the fork. Install the detent spring and ball. Install the fork retaining screw, and secure the screw with lock wire.
5. Install the other interlocking plunger in the bore, and install the fourth and fifth-speed shaft and fork. Install the detent spring and ball. Install the retaining screw, and secure it with lock wire.
6. Check the operation of the interlocking system. After coating the outer edge of new expansion plugs with sealer, install them, and remove the housing from the transmission case.

DESCRIPTION

TRANSMISSION

The Spicer 8000 series is a five-speed non-synchronized transmission available with either a direct drive or over-drive ratio in fifth gear. All gears except reverse are helical cut in constant mesh.

All rotating gears and shafts are carried on ball or roller bearings and are splash lubricated.

A clutch brake slows the input gear and related train when the clutch is disengaged, aiding smooth gear changes.

Power take-off openings are provided on both sides of the transmission.

ADJUSTMENTS

REAR MOUNT

1. With the transmission weight off the mounting studs, torque the upper retaining nuts to specification and install the cotter pins (Fig. 1).
2. Loosen the lower attaching nut and the lock nut as necessary so that the transmission rear end hangs freely.
3. Insert a feeler gauge (0.06 inch) between the lower attaching nut and its washer (Fig. 1). **Do not apply pressure to the engine or the transmission. If necessary, back up the lower retaining nut to the stud shoulder.**
4. Turn the lower attaching nut downward until there is slight pressure on the gauge.
5. Repeat steps 2, 3 and 4 for the other side of the support.
6. Torque the lock nuts to specification.

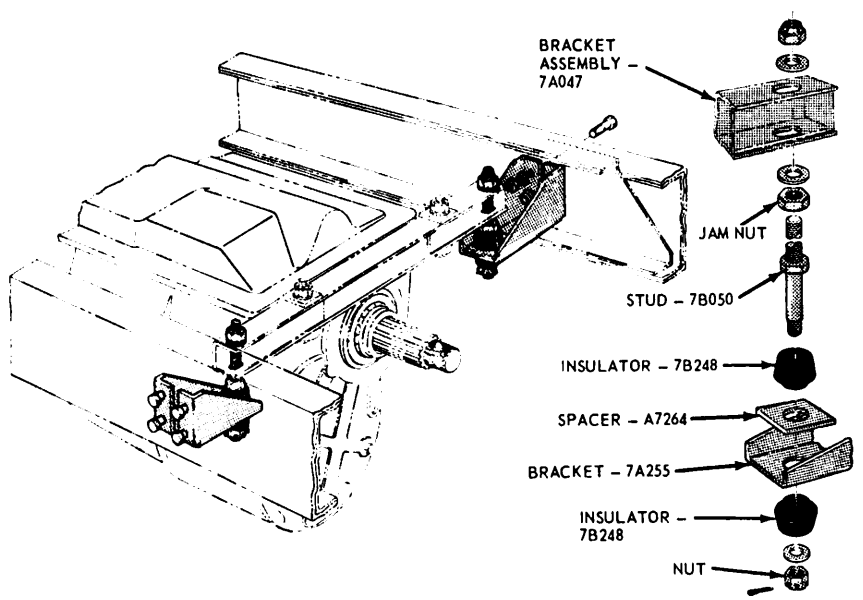

FIG. 1 Transmission Rear Supports

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate.
2. Position the shift lever in neutral. Remove the low and reverse gate plunger (Fig. 2).
3. Remove the gear shift lever housing or tower, and disconnect the parking brake lever if so equipped.
4. Disconnect the drive shaft (or coupling shaft) at the transmission. If the truck is equipped with a coupling shaft support, disconnect the support bracket and remove the coupling shaft. Disconnect the electrical lead from the right side of the transmission.
5. Disconnect the speedometer cable at the transmission. If the truck is equipped with a parking brake, remove the adjusting rod.
6. Disconnect the clutch linkage at the clutch release arm. If the truck is equipped with a slave cylinder, disconnect the slave cylinder return spring. Remove the slave cylinder mounting bolts and position the slave cylinder out of the way. If the vehicle is so equipped, shut off the fuel tank valves (both tanks) and remove the cross-over fuel line, and the shield.
7. Remove the clutch housing lower bolts. Position a jack under the transmission, and properly secure it (tool No. LRE 1790). Raise the transmission slightly to relieve pressure at the side rail mounting brackets. Remove the clutch housing upper bolts.
8. After removing the clutch housing to engine attaching bolts, pull the transmission rearward to clear the input shaft.
9. Raise the truck to provide clearance in removing the transmission. Install safety stands, and then remove the transmission from under the truck.

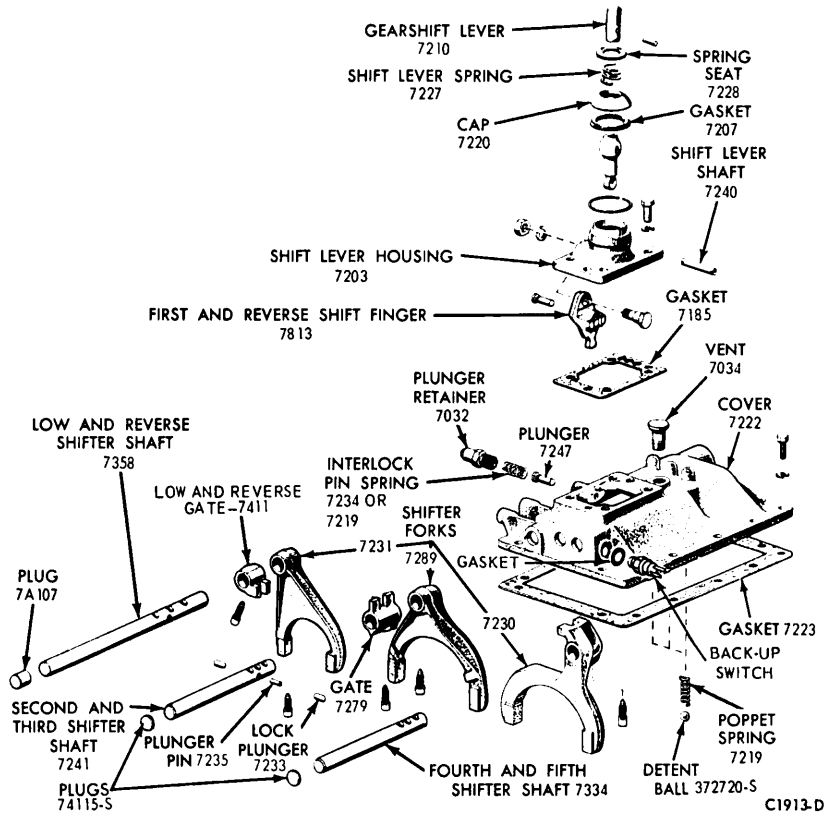

FIG. 2 Gear Shift Linkage

Installation

1. Place the transmission on a transmission jack (or chain hoist) and position it so that the input shaft splines are aligned with the clutch disc splines. The clutch release bearing must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. Install the clutch housing attaching bolts and torque them to specifications. Install the clutch housing dust cover.
3. Connect the clutch linkage to the clutch release arm. If the truck is equipped with a slave cylinder, install the slave cylinder and connect the slave cylinder return spring.
4. Connect the speedometer cable. If the truck is equipped with a parking brake, connect the adjusting rod. Connect the electrical lead to the right side of the transmission.
5. Install the coupling shaft in the support bracket, and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
6. Install the shift lever housing. Install the low and reverse gate plunger in the shaft finger before installing the shift lever housing. **When positioning the gear shift lever housing, always lower it straight down onto the gear shift housing.** Torque the gate plunger retainer to specification. If the vehicle is so equipped, apply sealer to the threads and install the cross-over fuel line. Open both of the fuel tank valves. Install the line shield.
7. Lower the truck to the floor, and install the floor plate and the floor mat.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Shift the transmission into reverse gear with a bar (Fig. 3). Remove 13 bolts and washers that secure the cover to the case. Lift the cover off the case.
2. Remove the clutch release cross-shaft to release yoke screws (Fig. 4). Remove the shafts, yoke and clutch brake discs.
3. Remove the nuts that attach the input gear bearing retainer. Using two bolts as a tool, pull the bearing retainer and the input gear assembly out of the case.
4. Remove the parking brake drum and the speedometer driven gear and bushing.
5. Lock the transmission in two gears, remove the companion flange nut and pull the companion flange off the mainshaft with a puller.
6. Remove the assembly and the mainshaft rear bearing cap.
7. Remove the speedometer gear and the bearing spacer.
8. Move the mainshaft as far to the rear as possible by tapping on the mainshaft first-speed gear (largest diameter gear).
9. Install a standard bearing puller on the mainshaft rear bearing and remove it from the rear of the mainshaft (Fig. 5).
10. Remove the transmission rear cover, using a bolt as a puller (Fig. 6).
11. Remove the overdrive shift fork guide rod with a bolt and puller. Remove the fork from the case (Fig. 7).
12. Shift the transmission into two gears. Remove the countershaft rear cotter key and nut (Fig. 8).
13. Remove the countershaft over-drive clutch gear by pulling on the collar or by attaching a puller to the three threaded holes in the clutch gear (Fig. 9).
14. Remove the fifth (or over-drive) countershaft gear and thrust washer (Fig. 10).
15. Pry the mainshaft fifth (or over-drive) gear off the shaft (Fig. 11).
16. Tap the mainshaft assembly toward the rear of the case and install a split-type puller on the mainshaft center bearing outer race. Tap the mainshaft forward as far as possible and then to the rear again. Secure a new grip on the bearing and repeat the process until the bearing is loose on the shaft (Fig. 12).
17. Remove the mainshaft and gears from the case (Fig. 13) by lifting the front of the mainshaft up and forward with a sling. The center bearing and the low-speed gear needle bearings will come off during the above operation.
18. Remove the lock wire from the countershaft rear bearing retainer nuts. Remove the nuts and the bearing retainer (Fig. 14).
19. Remove the reverse idler shaft with a puller (Fig. 15).
20. Remove the reverse idler gear. Two identical caged roller bearing assemblies support the gear and sleeve. The sleeve is keyed to the gear.
21. Pry the countershaft toward the rear of the case until a bearing puller can be installed on the rear bearing. Remove the bearing (Fig. 16). Remove the countershaft assembly (Fig. 17).

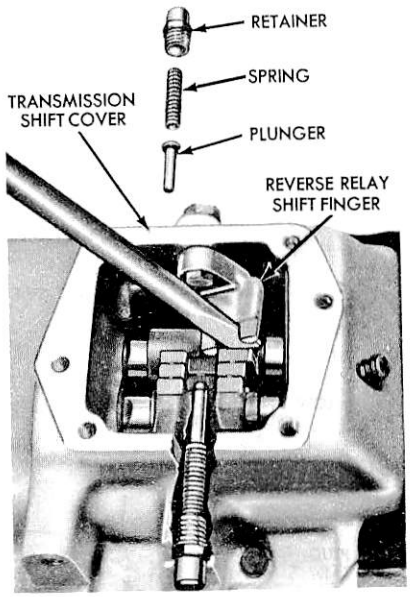

FIG. 3 Removing Over-Drive and Reverse Plunger and Spring

Assembly

1. Lower the countershaft assembly into the case, rear end first and down, so the rear of the countershaft enters the rear bearing bore (Fig. 17). Lower the front of the countershaft assembly until the front bearing will enter its bore in the case. Tap the rear of the shaft until the front bearing enters the bore.
2. Install the countershaft rear bearing, with the snap ring to rear, in the bore and on the countershaft. Tap into place with a tool that contacts the inner bearing race.
3. Assemble the reverse idler gear, sleeve, key and bearings. Place them in the case with the shift fork collar toward the rear of the transmission case (Fig. 15). The sleeve small diameter must go toward the front. It is marked Front.
4. Install the reverse idler shaft. The flat on the rear end of the shaft must align with the tang on the edge of the countershaft rear bearing retainer (Fig. 15).
5. Install the countershaft rear bearing retainer, with the tang locking the idler shaft. Install the bolts and

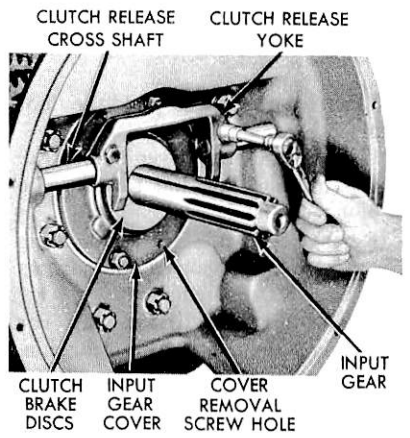

FIG. 4 Removing or Installing Clutch Yoke

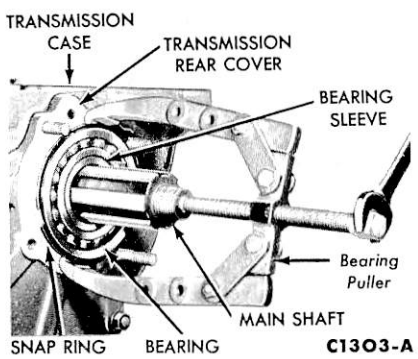

FIG. 5 Removing Mainshaft Rear Bearing

torque to specifications. Install the lock wire through the bolt heads.

6. Assemble a sling onto the mainshaft and gear assembly, as in removal, and lower the assembly into the case, rear end first. Start the center support bearing over the rear of the shaft and into the case center web with the bearing snap ring (if so equipped) toward the rear (Fig. 13).
7. Install the input gear, bearing and cap assembly, with a new gasket, into the front of the case. Pilot the mainshaft front bearing into place in the bore of the input gear. Start, but do not tighten the nuts.
8. Drive the mainshaft center support bearing into place with a tube or an arbor that bears on the bearing inner race.
9. Install the fifth (or over-drive) gear onto the rear of the mainshaft.
10. Install the fifth (or over-drive) gear thrust washer and gear onto the rear of the countershaft with the clutch teeth toward the rear (Fig. 10). Install the countershaft fifth (or over-drive) clutch collar and gear with the large diameters of the collar and gear toward the rear. Install the clutch gear nut and torque to specification (Fig. 8).
11. Place the pin on the inside of the mainshaft rear bearing sleeve and press the sleeve onto the rear of the mainshaft and against the mainshaft fifth (or over-drive) gear. Be sure the pin is aligned with a spline groove and the ground surface of the hub is toward the rear.
12. Install the fifth (or over-drive) shift fork and shaft guide. The long hub of the shift fork must face toward the front (groove in shift fork forward of the collar). Place the shift fork guide rod into the hole in the rear of the case through the shift fork and into the hole in the center web of the case.
13. Install the transmission rear cover, using a new gasket. Do not tighten the bolts.
14. Install the mainshaft rear bearing. It must pilot in the cover and in the case.
15. Install the mainshaft rear bearing thrust washer and speedometer drive gear.
16. Using a new gasket, install the rear bearing cap onto the transmission cover. Torque the cap bolts to specification.
17. Place the speedometer driven gear and bushing in the mainshaft rear bearing cap and secure with the two bolts and washers.
18. Torque the transmission rear cover bolts to specification.
19. Torque the input gear bearing cap bolts to specification.
20. Install the clutch release yoke and cross-shafts in the clutch housing. Install the clutch brake discs (Fig. 4).
21. Shift the transmission and the cover assembly to reverse position and install the shift cover, using a new gasket. Be sure the forks line up with the shift collars. Install the cover bolts and torque them to specification.

SUB-ASSEMBLIES

MAIN SHAFT

Disassembly

1. Place the mainshaft assembly, front up, in an arbor press as shown in Fig. 18.
2. Spread the snap ring (behind the front bearing) out of its groove. Using a tool similar to the one shown in Fig. 18, press the bearing, third and fourth-speed clutch gear, mainshaft third-speed gear, sleeve and mainshaft second-speed gear from the mainshaft.

Be careful not to lose the sleeve lock balls or the second and third-speed gear needle bearings (Fig. 19).

3. Remove the snap ring from between the drive gear and the bearing cap (Fig. 20). Pull the cap off toward the front of the drive gear.
4. Clean the staked areas of the nut and the gear and remove the nut with a spanner wrench. **The threads are left-hand.**
5. Press the bearing off the shaft.

Assembly

1. Press the ball bearing on the input gear with the shielded side of the bearing toward the gear. **Use a tool or an arbor that will bear on the inner bearing race.**
2. Install the bearing lock nut on the gear and tighten. Stake the nut into the slots in the gear shaft.
3. Place the bearing cap over the bearing and press into position.
4. Insert the snap ring into the slot in the bearing cap (Fig. 20).
5. Using Lubriplate or a comparable viscosity grease, assemble 2 rows of 71 needle bearings each, with the narrow spacer between them, onto the shaft diameter just to the front of the center splined area (Fig. 20). A space of one needle will exist in each row when properly assembled. Install the mainshaft second-speed gear over the needle bearings, with the clutch teeth toward the rear.
6. Install the mainshaft third-speed gear sleeve onto the front of the shaft with the flange facing the rear and the notches aligned with the splines and balls.
7. Place 2 rows of 71 needle bearings per row onto the sleeve with a spacer between the rows. Use grease.
8. Slide the mainshaft third-speed gear over the needle bearings with the clutch teeth toward the front (Fig. 19).
9. Press the mainshaft third and fourth-speed clutch gear onto the front of the mainshaft, flat side toward the rear and the clutch hub toward the front (Fig. 18).
10. Install the snap ring in its groove on the front of the mainshaft.
11. Press the front ball bearing on, with the beveled edge of the inner race toward the rear.
12. Press the third and fourth-speed clutch collar on the third and fourth-speed clutch gear, with the long portion of the hub toward the rear.
13. Slide the first and second-speed clutch gear onto the splines, with the shift fork collar toward the rear (Fig. 21).
14. Using grease, install 2 rows of 71 needle bearings per row, with the wide spacer between them, on the shaft diameter to the rear of the center splined area.
15. Place the mainshaft first-speed gear over the needle bearings with the clutch teeth toward the front.
16. Grease one side of the first-speed gear thrust washer and place it on the mainshaft with the greased side toward the first-speed gear. Set the mainshaft assembly aside.

COUNTERSHAFT

Disassembly

1. Remove the countershaft front bearing with a puller (Fig. 22).
2. Remove the snap ring from the front of the countershaft.
3. Press the countershaft drive gear off the countershaft, using a suitable arbor (Fig. 23). The remainder of the countershaft gears are removed in the same manner, using suitable arbors.

Assembly

1. Place the key in the countershaft second-speed gear position key-way. **Be sure the key is seated in the keyway.** Use the proper size arbor and press the second-speed gear on the shaft with the chamfered bore end toward the rear.
2. Insert the third-speed gear key in the shaft and press the third-speed gear on the shaft, with the long hub of the gear toward the front (away from the second-speed gear).

3. Place the power take-off gear key in position on the shaft. Press the power take-off gear on the shaft, with the long hub toward the front.
4. Insert the drive gear key in the shaft. Press the drive gear on with the long hub facing the power take-up gear (Fig. 24).
5. Install the snap ring in its groove in the front of the countershaft. Press the countershaft front bearing on. **Use an arbor that contacts the inner bearing row.**

GEAR SHIFT HOUSING

Disassembly

1. (It is not necessary to disassemble the shift cover unless the detent springs are weak or broken or if the forks and shafts are worn). Place the shift cover assembly on its side in a vise. Use brass or aluminum vise jaw covers. Remove the interlock hole plug.
2. Remove the lock wire and set screws from the reverse shift fork and bracket (Fig. 25).
3. Tap the reverse shift rod out through the front of the cover. The reverse rod hole plug will come out during the above operation. Hold a cloth over the rear of the rod, the poppet ball, and the spring hole, as the rear of the rod passes the hole. The ball will fly out. Remove the shift fork and bracket.
4. Remove the interlock through the hole in the side of the cover. A magnet will help.
5. Remove the lock wire and the set screw from the third and fourth-speed shift fork. Tap the third and fourth-shift rod out through the front of the cover. The plug and poppet ball will come out in the same manner as the reverse rod plug and ball did. Remove the third and fourth-speed shift fork. If not done previously, remove the small interlock pin from the rod.
6. Remove the short interlock through the hole in the side of the cover.
7. Remove the lock wire and set screw from the first and second-speed shift fork and bracket. Tap the first and second-speed shift rod out of the front of the cover. Do not lose the poppet ball. Remove the shift fork and bracket.
8. Remove the interlock pin and interlock.
9. Cut the lock wire from the set screws that secure the reverse fork and bracket to the shift rod. Remove the set screws, the rod, fork and bracket. Be careful of the poppet ball. Remove the lock-out plunger from the over-drive rod bracket.
10. Remove the four poppet ball springs from the holes in the cover.
11. Loosen the nut and washer, on the outside of the cover, and remove the stud, reverse relay shift finger and lock-out plunger from the cover.

Assembly

1. Place the reverse relay shift finger stud in the shift finger. The head of the stud must be on the same side as the shift slot (Fig. 25).
2. Place the reverse lock-out plunger in the reverse relay shift finger.
3. Position the reverse shift finger, and tap the stud through the shift cover housing. Secure the stud with the nut and washer.
4. Set the four shift rod poppet ball springs in the holes provided in the cover (Fig. 25).
5. Place the over-drive lock-out plunger in the over-drive shift rod bracket and slide the over-drive shift rod into the hole in the shift cover.
6. Start the shift rod in the cover and place the over-drive rod bracket on the shift rod.
7. Place the poppet ball on the spring, hole it down and slide the rod past it.
8. Position the upper over-drive shift fork on the rod, line up the set screw holes in the bracket and fork and install the set screws. The long hub of the fork will be toward the front of the cover. Torque the set screws to specification and lock wire.
9. Place a short interlock into the hole in the cover and push it through to the over-drive shift rod.
10. Slide the first and second-speed shift rod into the second hole from the right side of the front of the cover. Place the first and second shift rod bracket on the rod.
11. Install a small interlock pin in the rod. Place a poppet ball on the poppet spring. Hold the ball and spring compressed and slide the rod past the cover boss. Place the first and second-speed shift fork on the rod, with the long hub toward the front, and line up the set screw holes in the fork, bracket and rod. Install the set screws and torque to specification. Wire the screw heads.
12. Install a short interlock into the cover and push it through to the first and second-speed rod.
13. Slide the third and fourth shift rod into the front of the cover. Place a small interlock pin in the rod. Place the third and fourth-speed shift fork on the rod, with the long hub toward the front. Set the poppet ball on the spring and depress it. Slide the rod through the case boss. Line up the holes and install the set screw. Torque to specifications and lock wire.
14. Place the long interlock in the cover hole and push it over to the third and fourth-speed rod.
15. Start the reverse shift rod into the remaining hole in the front of the cover. Place the reverse bracket in position and slide the rod through it. Set a poppet ball on the poppet spring, hold down and push the shift rod past it. Install the reverse shift fork, line up and install the set screws. Torque them to specification and lock wire them (Fig. 3).
16. Install four expansion plugs in the shift rod holes in the front of the cover and expand them by striking with a flat-ended bar and hammer.
17. Install the interlock cross-hole plug in the side of the shift cover.

DESCRIPTION

TRANSMISSION

The Model 5H74 transmission is of the constant mesh type, having five speeds forward and one reverse. All of the forward gears are helical type gears (Fig. 1).

The forward speed gears on the mainshaft are in constant mesh with the countershaft gears but float on the mainshaft until locked into engagement with the countershaft gears by means of sliding clutch gears.

ADJUSTMENTS

GEAR SHIFT LINKAGE—W-SERIES

1. Place the gear shift lever in the neutral position.
2. Loosen he bolts on the shift rod turnbuckle (Fig. 2). Then rotate the turnbuckle until the rear of the shift knob is located 12 to 12 1/2 inches from the front face of the instrument panel. Torque the lower turnbuckle bolt.
3. While holding the rear cross-shaft lever in the extreme right position, move the gear shift lever (in neutral) until the outside edge of the shift knob is 2 29/32-3 13/32 inches from the console edge. Torque the upper turnbuckle bolt.
4. Check the operation of the gear shift lever in all positions and readjust if necessary.

REAR MOUNT

ALL EXCEPT W-SERIES

1. With the transmission weight off the mounting studs, torque the upper retaining nuts to specifications, and install the cotter pins (Fig. 3).
2. Loosen the lower retaining nut and the lock nut as necessary so that the transmission rear end hangs freely.
3. Insert a feeler gauge (0.06 inch) between the lower retaining nut and its washer (Fig. 3). **Do not apply pressure to the engine or the transmission. If necessary, back up the lower retaining nut to the stud shoulder.**
4. Turn the lower retaining nut downward until there is slight pressure on the gauge.
5. Repeat steps 2, 3 and 4 for the other side of the support.
6. Torque the lock nuts to specifications.

W-SERIES

1. With the transmission connected at the engine and the transmission jack removed, torque the transmission support-to-transmission case bracket bolts to specifications.
2. Check the clearance between the transmission support and the frame side rail brackets (Fig. 3) and install the necessary washers (shims) to obtain zero clearance. Install the attaching bolts and torque to specifications.

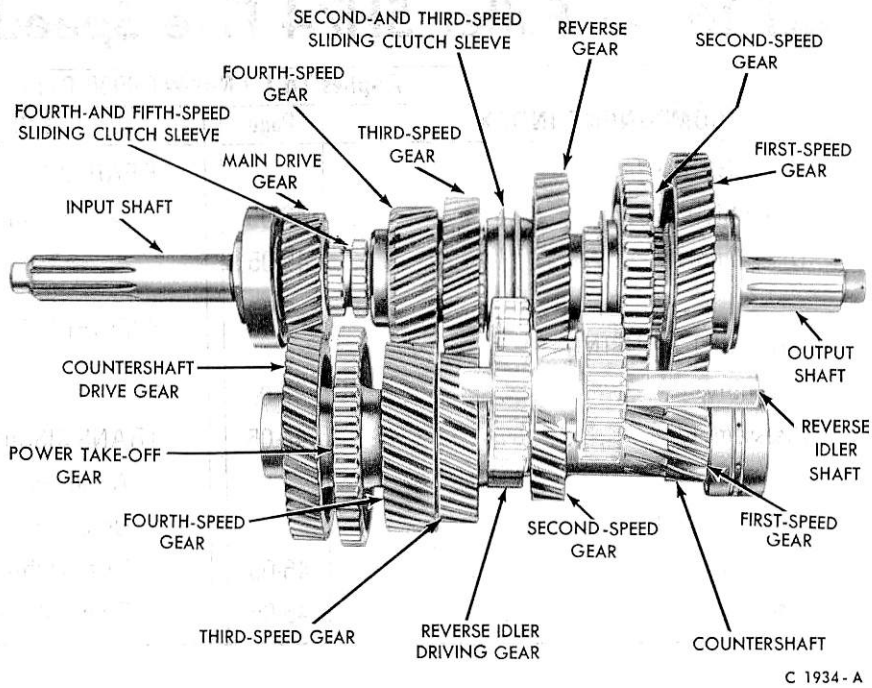

FIG. 1 Gear Train

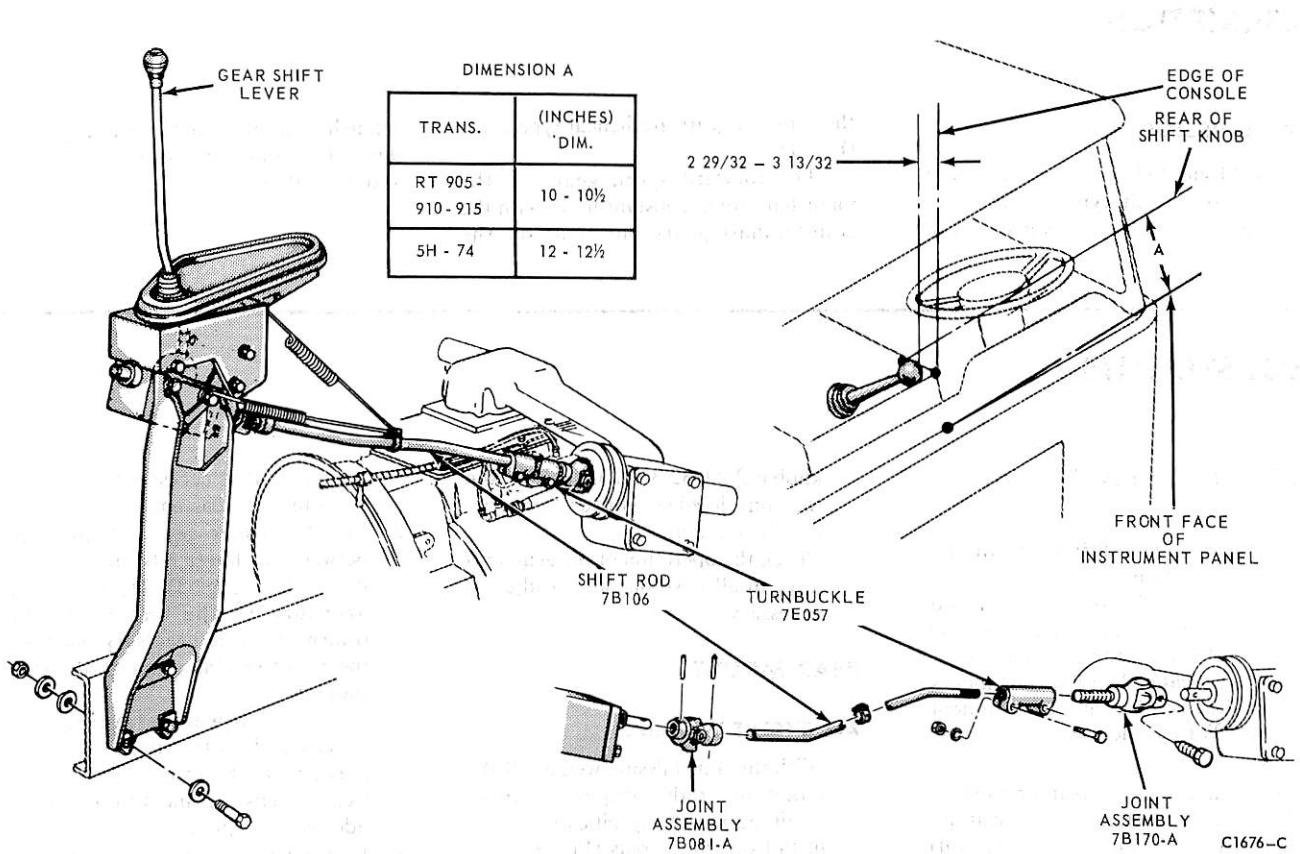

FIG. 2 Gear Shift Linkage Adjustments—W-Series

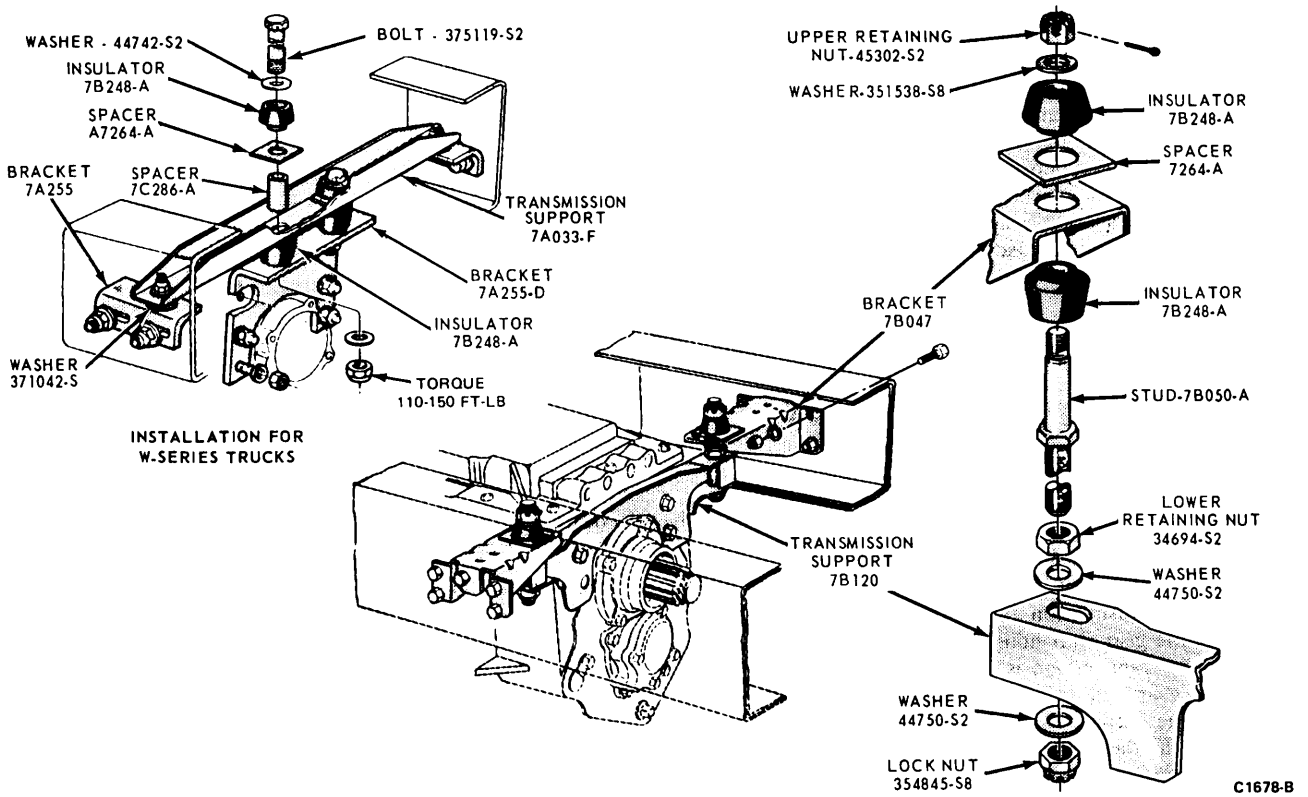

FIG. 3 Transmission Rear Support

REMOVAL AND INSTALLATION

TRANSMISSION

REMOVAL

1. Disconnect the drive shaft.
2. Disconnect the speedometer cable at the transmission.
3. On a W-Series truck, remove the four nuts and washers that secure the transmission support to the transmission (Fig. 3).
4. Disconnect the clutch linkage at the clutch release arm. If the truck is equipped with a slave cylinder, disconnect the slave cylinder mounting bolts and position the slave cylinder out of the way.
5. After cleaning the area around the cross-shaft housing, remove the housing and tie it out of the way. Cover the opening in the gear shift housing to prevent the entry of dirt.
6. Remove the bottom fuel tank support arm for a W-model.
7. Remove all but two of the transmission to flywheel housing attaching bolts. Remove the dust cover from the bottom of the clutch housing.
8. Position a transmission jack and raise the transmission slightly to relieve pressure at the side rail mounting brackets.
9. Remove the bolts that attach the side rail brackets to the side rails, and remove the brackets and transmission support as an assembly.

   On a W-Series truck, remove the bolts and washers that attach the transmission support to the frame side rail brackets. Mark the washers so they can be reinstalled on the same side from which they were removed. After removing the lock wire, remove the transmission support-to-transmission case bracket bolts, washers, insulators, and spacers and remove the support (Fig. 3).
10. After removing the remaining transmission to flywheel housing attaching bolts, pull the transmission rearward to clear the input shaft.
11. Raise the truck to provide clearance in removing the transmission. Install safety stands, and then remove the transmission from under the truck. **On a W-Series truck, the transmission must be lifted out rather than lowered.**

INSTALLATION

1. Place the transmission on a transmission jack (or chain hoist) and position the transmission so that the input shaft splines are aligned with the clutch disc splines. The clutch release bearing must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. Install the clutch housing attaching bolts and torque them to specifications. Install the clutch housing dust cover.
3. On a W-Series truck, support the

transmission with a transmission jack and remove the hoist chains.

4. Position the transmission rear support and brackets to the transmission and frame side rails. Install the attaching bolts and nuts. Adjust the rear support mounting studs.

On a W-Series truck, install the support-to-transmission case bracket bolts, washers, insulators and spacers. Torque the bolts to specifications and secure them with lock wire. If necessary, adjust the clearance between the transmission support and frame side rail brackets, and install the attaching bolts. Torque the bolts to specifications. Be sure to remove the transmission jack before making rear mount adjustment.

5. Install the fuel tank support arm on a W-model.
6. Connect the clutch linkage to the clutch release arm. If the truck is equipped with a slave cylinder, install the slave cylinder and connect the slave cylinder return spring.
7. Install the cross-shaft housing, and torque the mounting bolts to specifications.
8. Connect the speedometer cable.
9. Connect the drive shaft and lower the truck to the floor.
10. Start the engine and check for leaks.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

DISASSEMBLY

1. With the transmission in neutral, remove the gear shift housing.
2. While the transmission is draining, lock the gear train in two gears and remove the output shaft flange nut.
3. Remove the flange and brake drum as a unit, and disconnect the parking brake linkage, as necessary, so that the brake shoe assembly can be removed.
4. Remove the brake shoe assembly.
5. Remove the output shaft rear bearing retainer and gasket, and remove the speedometer drive gear. Remove the oil seal from the retainer.
6. After removing the clutch release mechanism, remove the six stud nuts (inside the clutch housing), and then remove the clutch housing.
7. Remove the input shaft bearing retainer and gasket, and then pull out the input shaft and bearing assembly. If necessary, use a soft-drift from inside the case. Remove the bearing retaining snap ring from the case bore.
8. Mount the input shaft assembly in a soft-jawed vise and relieve the bearing nut peening. Remove the nut. **This nut has a left-hand thread.**
9. If the bearing is to be replaced, press or jar it from the shaft.
10. Remove the countershaft rear bearing adapter cap and gasket.
11. Remove the retainer plate from the rear end of the countershaft.
12. Remove the countershaft rear bearing adapter bolts, and then remove the adapter as shown in Fig. 4.
13. Drive the output shaft forward until it stops solidly, and then drive it to the rear until the rear bearing snap ring is exposed.
14. Using tools OTC-938, 924, 930-D, and 952, remove the bearing. If the bearing is to be replaced, remove the snap ring.
15. Remove the output shaft and gears, except the sliding gears. Lift the sliding gears out of the case.
16. Remove the countershaft rear bearing cones, cups, and spacer from the retainer.
17. After removing the reverse idler shaft retainer, remove the shaft, using tool T57T-7140-A. Remove the idler gear and bearings from the case.
18. Move the countershaft rearward to clear the front bearing, and then remove the shaft and gears from the case.
19. Remove the countershaft front bearing retainer, gasket, bearing, and spacer from the case.

ASSEMBLY

1. Install the countershaft front bearing in the case bore.
2. Position the front bearing spacer and gasket, and install the retainer.
3. Position the countershaft assembly in the case, and then tilt the case so that its rear face is up.
4. Position two wood or fiber blocks of equal thickness between the drive gear and the case (Fig. 5).
5. Position the inner bearing outer race in the adapter, and then apply sealer B5A-19554-A to the adapter gasket.
6. Make sure the adapter oil return hole is aligned, and then install the gasket and the adapter.
7. Using the tool shown in Fig. 5 install the inner bearing cone.
8. Position the spacer, and install the outer bearing cone. Position the

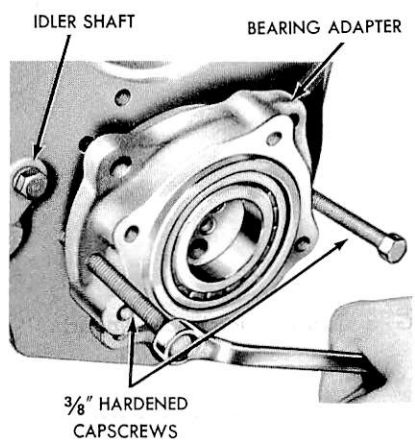

FIG. 4 Removing Countershaft Bearing Adapter

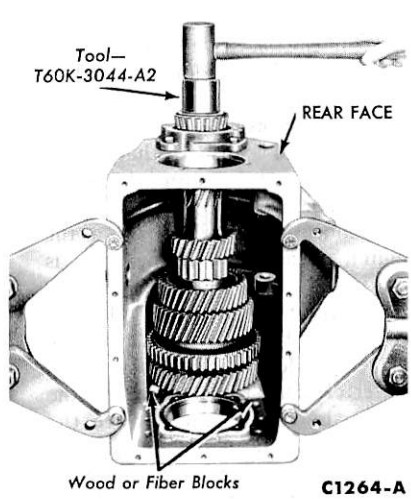

FIG. 5 Installing Countershaft Rear Bearing

outer bearing outer race.
9. Install the bearing lock plate and safety wire the bolts.
10. Apply sealer B5A-19554-A to the adapter cap gasket, and install the gasket and cap.
11. After tilting the case back to its normal position, install the idler gear and shaft. Be sure the flat on the shaft will align with the lock plate.
12. Install the lock plate.
13. Position the output shaft sliding gears in the case (Fig. 6), and then position the output shaft assembly in the case. Check for proper gear engagement (Fig. 1).
14. Install the rear bearing (Fig. 7).
15. If the input shaft bearing was removed, install a new bearing with its shield toward the shaft splines. Install the bearing nut and stake it at the milled slots.
16. Install the input shaft bearing snap ring in the case bore.
17. Position the input shaft assembly, and install the bearing retainer gasket and retainer. Use B5A-19554-A sealer.
18. Install the clutch housing and the speedometer drive gear.
19. After installing a new seal in the rear bearing retainer, install the gasket and retainer. Use B5A-19554-A sealer.
20. Install the parking brake shoe assembly, and connect the brake linkage.
21. With the transmission locked in two gears, install the brake drum and flange. Torque the flange nut to specification.
22. Fill the transmission with lubricant as specified.
23. Adjust the parking brake.
24. Install the gear shift housing, using B5A-19554-A sealer on the gasket.

SUB-ASSEMBLIES

OUTPUT SHAFT

Disassembly

1. Remove the pilot bearing (Fig. 8) and the sliding clutch sleeve.
2. Pry the fourth-speed gear washer key from its keyway between the shaft splines.
3. Align the fourth-speed gear washer with the output shaft grooves (Fig. 9), and then remove the gear and washer.
4. Position the shaft and gears in a press, using the rear face of the third-speed gear (Fig. 6) as a base. Press the shaft no more than 5/8 inch through the third-speed gear and the thrust washer. **Travel of the shaft is limited to 5/8 inch by the small Woodruff key under the bushing. Pressing the shaft further will shear the key and damage the washer.**
5. Move the gear and the washer rearward to their original positions against the shaft shoulder. Then with pry bars, move he bushing forward until the Woodruff key is completely exposed (Fig. 10). Remove the key.
6. Remove the thrust washer, the third-speed gear, the bushing, and the clutch sleeve.
7. Press the output shaft through the third-speed gear bushing, the second-speed gear and the sleeve hub.
8. Remove the two remaining Woodruff keys.

Assembly

1. Install the Woodruff keys for the sleeve hub and the third-speed gear bushing (Fig. 6).
2. Position the second-speed gear (clutching teeth to the front) on the output shaft, and then press the sleeve hub (recessed end to the front) tightly against the gear.
3. Press the third-speed gear bushing onto the shaft and against the sleeve hub. Position the clutch sleeve on its hub.
4. Position the third-speed gear (clutch teeth to the rear) on its bushing.
5. Install the thrust washer, chamfer to the rear, and install the remaining Woodruff key.
6. Press the fourth-speed gear bushing onto the shaft, and position the fourth-speed gear (hub forward) on the bushing.
7. Install the retaining washer, and measure the clearance between the fourth-speed gear and its thrust washer. If the clearance is not 0.006-0.012 inch, select the required retaining washer to result in the specified end play.
8. Install the retaining washer key and the clutch sleeve (recessed end to the rear).
9. Install the pilot bearing.

COUNTERSHAFT

Disassembly

1. After removing the drive gear snap ring (Fig. 11), remove the front bearing inner race as shown in Fig. 12.
2. Press the gears from the shaft, one at a time.
3. Remove the Woodruff keys.

Assembly

1. Install the Woodruff keys, and press on the gears, one at a time (Fig. 11). Press the front bearing inner race on, and install the drive gear snap ring.

GEAR SHIFT HOUSING

Disassembly

1. Remove the detent spring cover and gasket (Fig. 13). Remove the four springs and balls.
2. Remove the set screw and jam nut.
3. Position the housing (right-hand side up) in a vise, and remove the set

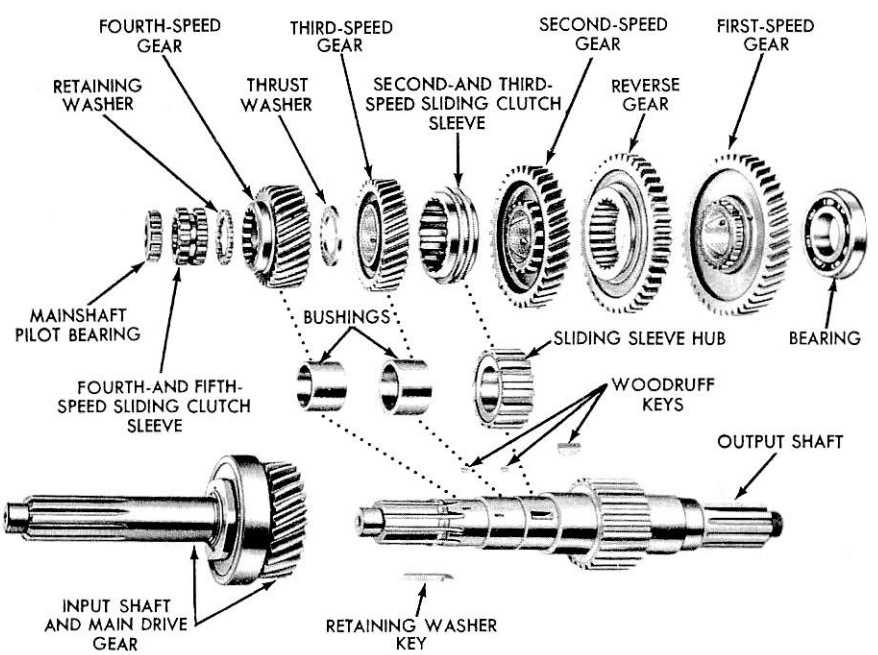

FIG. 6 Input Shaft and Output Shaft

screws from the forks and gates and the block.

4. Remove the Welch plugs.
5. Remove the shift shafts one at a time, beginning with the rocker arm shaft and working down. **Any shaft out of neutral position will lock the remaining shafts in the housing. Do not lose the interlock pin and balls as the low and reverse shaft is removed (Fig. 13).**
6. Remove the pivot pin and rocker arm.

Assembly

1. Position the housing (left-hand side up) in a vise, and install the rocker arm and pivot pin (Fig. 14).
2. Insert the rocker arm shift shaft through the webs and gates (Fig. 15). Install the set screws.
3. Insert the second-third shaft into the housing and through its fork. Install the set screw.
4. Position a 3/4 inch interlock ball in the housing opening between the second-third and the fourth-fifth shafts.
5. Insert the fourth-fifth shaft into the housing and through its fork. **Insert the interlock pin into the shaft as the neutral notch enters the web (Fig. 16). Install the lock screw.**
6. Install the remaining 3/4 inch interlock ball.
7. Insert the low and reverse shaft through the housing, block, and fork. Install the set screws.
8. Safety-wire all set screws and the pivot pin retaining bolts.
9. Install the four 1/2 inch steel balls and the detent spring. **Be sure all shafts are in neutral position so that the balls will fit into their slots.**
10. Install the detent spring cover and a new gasket.
11. Install Welch plugs in the shift shaft openings of the housing.
12. Start the set screw and jam nut, tighten the screw until it bottoms; back it off one half turn, and tighten the jam nut.

DESCRIPTION

TRANSMISSION

The Fuller five-speed, twin countershaft Model T-905 transmission (Fig. 1) has five forward speeds and one reverse speed and is designed for heavy duty vehicles. The twin countershaft design divides the torque equally between the shafts and gears, thus providing a high capacity to weight ratio. The countershafts, identical except for the PTO gears, are short and bearings are of a relative low capacity due to the split torque principle. All gears are constant mesh and have spur type teeth.

The mainshaft gears are not journaled to the mainshaft but are locally axially by washers and held in position by rotation of the countershaft gears, eliminating the need for bushings and sleeves. The mainshaft floats free, receiving only minor radial loads. Mainshaft vertical displacement to conform to clutched gear positions is allowed by rod-like springs which resist float to right or left.

Gears are clutched by internal splines in the hubs of gears. The sliding clutch gears with short conical clutching teeth provide shorter and easier shifts.

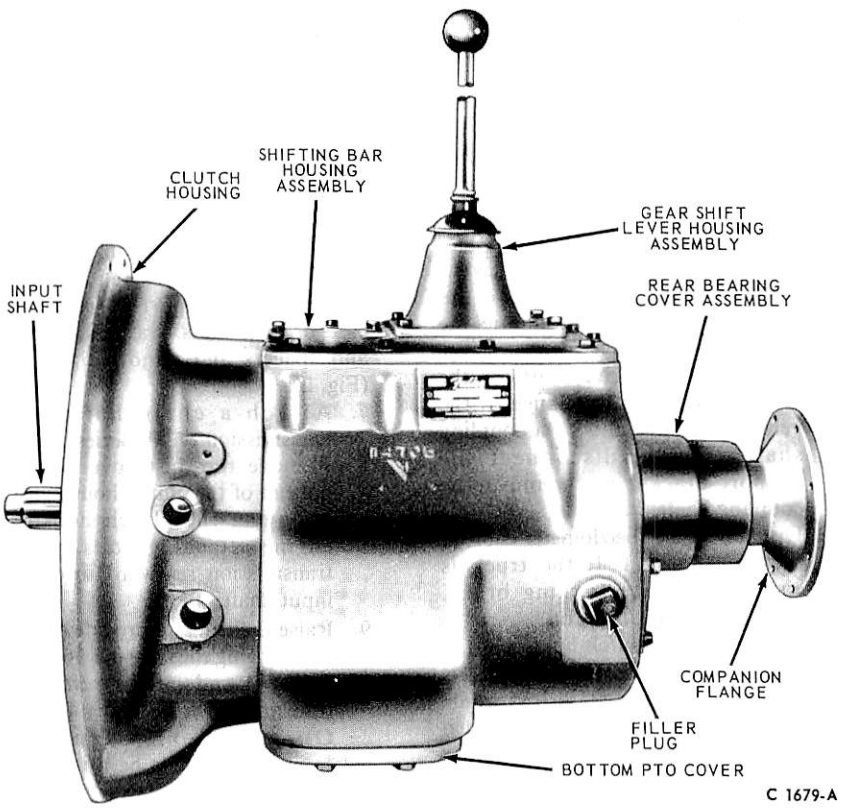

FIG. 1 Five-Speed Twin Countershaft Transmission— Model T-905

ADJUSTMENTS

REAR MOUNT

W-SERIES

1. With the transmission connected at the engine and the transmission jack removed, torque the transmission support-to-transmission case bracket bolts to specifications.
2. Check the clearance between the transmission support and the frame side rail brackets (Fig. 2) and install support-to-transmission case bracket bolts. Torque to specifications.

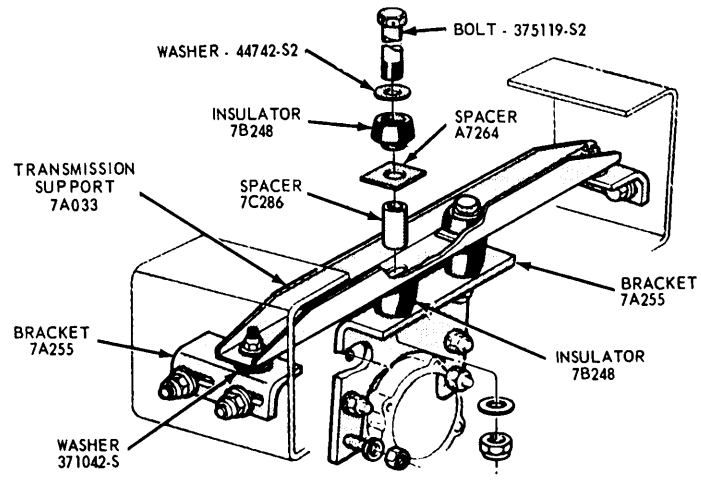

FIG. 2 Transmission Rear Support—W-Series

REMOVAL AND INSTALLATION

TRANSMISSION

Removal

1. Remove the floor mat and the floor plate. Remove the gear shift lever.

On a W-Series truck, remove the cross-shaft housing bolts and tie the housing out of the way.

2. Disconnect the drive shaft (or the coupling shaft) at the flange. If the vehicle is equipped with a coupling shaft support, disconnect the support bracket and remove the coupling shaft.
3. Disconnect the speedometer cable at the transmission. If the truck is equipped with a parking brake, remove the adjusting rod.
4. Disconnect the clutch linkage at the clutch release arm. If the truck is equipped with a slave cylinder, disconnect the slave cylinder return spring. Remove the slave cylinder mounting bolts and position the slave cylinder out of the way.
5. Position a jack under the transmission. Raise the transmission slightly to relieve pressure at the side rail mounting brackets.
6. Remove the side rail bracket stud nuts, insulators and reinforcements. Then remove each side rail bracket. On W-Series trucks, remove the bolts and washers that attach the transmission support to the frame side rail brackets. Mark the washers so they can be reinstalled on the same side from which they were removed. After removing the lock wire, remove the transmission support-to-transmission case bracket bolts, washers, insulators and spacers and remove the support (Fig. 2).
7. Attach a chain hoist to the transmission on W-Series trucks.
8. Remove the dust cover from the bottom of the clutch housing. After removing the clutch housing to engine attaching bolts, pull the transmission rearward to clear the input shaft.
9. Raise the truck to provide clearance in removing the transmission. Install safety stands, then remove the transmission from under the truck. **On a W-Series truck, the transmission must be lifted out.**

Installation

1. Place the transmission on a transmission jack (or chain hoist) and position the transmission so that the input shaft splines are aligned with the clutch disc splines. The clutch release bearing must be properly positioned in the release lever fork. Slide the transmission forward until it is in position on the clutch housing.
2. Install the clutch housing attaching bolts and torque them to specifications. Install the clutch housing dust cover.
3. On a W-Series truck, support the transmission with a transmission jack and remove the hoist chains.
4. Install the side rail brackets and torque the mounting bolts to specifications. Position the rear support studs, insulators, washers and nuts to the side rail brackets and transmission support. Adjust the studs.

On W-Series trucks, install the support-to-transmission case bracket bolts, washers, insulators and spacers. Torque the bolts to specifications and secure them with lock wire. If necessary, adjust the clearance between the transmission support and frame side rail brackets and install the attaching bolts. Torque the bolts to specifications. Be sure to remove the transmission jack before making rear mount adjustments.

5. Connect the clutch linkage to the clutch release arm. Install the slave cylinder and connect the slave cylinder return spring (if so equipped).
6. Connect the speedometer cable. If

the truck is equipped with a parking brake, connect the adjusng rod.
7. Install the coupling shaft in the support bracket and connect the support bracket to the support plate. Connect the coupling shaft (or the drive shaft) at the transmission.
8. Install the shift lever housing. **When positioning the gear shift lever housing, always lower it straight down onto the gear shift housing.**
9. Lower the truck to the floor and install the floor plate and the floor mat.

DISASSEMBLY AND ASSEMBLY

TRANSMISSION

Disassembly

1. Remove the bolts that attach the shifting bar housing to the transmission case. Tap the housing with a soft hammer to free it from the case, then lift it from the transmission.
2. Lock the mainshaft by engaging two gears at one time with the sliding clutches.
3. Remove the companion flange attaching nut, then remove the flange. Remove the rear bearing cover attaching screws. Pry the cover from the output shaft and case as shown in Fig. 3.
4. Remove the speedometer drive gear or spacer and the bearing washer from the output shaft or from the cover.
5. Remove the rear bearing from the output shaft (Fig. 4). If the bearing remains in the rear cover, remove it from the cover.
6. Remove the lock wire and the two flat key attaching bolts (Fig. 5). Lift the two keys from the output shaft.
7. Remove the output shaft as shown in Fig. 6.
8. Remove the clutch release mechanism from the flywheel housing.
9. Remove the four bolts, six nuts and lock washers that attach the flywheel housing to the transmission case.

The disassembly and assembly of the basic T-905 transmission is the same as the RT-910 and RT-915 transmission after all exterior components have been removed from them. The exceptions are that the right countershaft bearing on the T-905 must be removed before the mainshaft can be lifted from the case. Also the T-905 has 2 keys in the mainshaft.

Assembly

Refer to Part 16-61 for the assembly of the basic transmission, then:

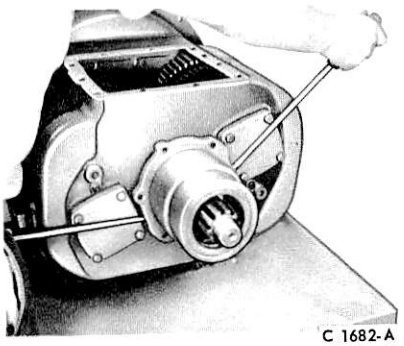

FIG. 3 Removing Rear Bearing Cover

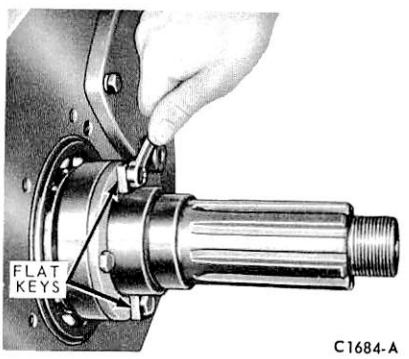

FIG. 5 Removing Output Shaft Attaching Screws

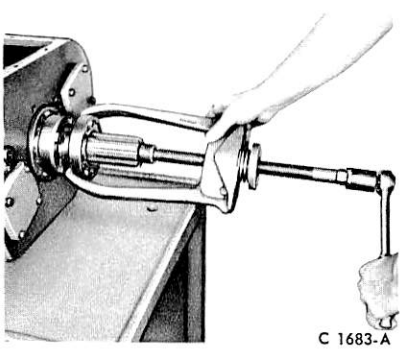

FIG. 4 Removing Rear Bearing From Output Shaft

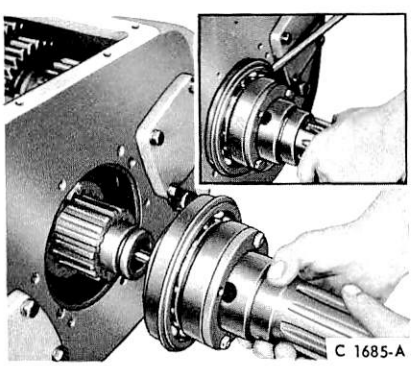

FIG. 6 Removing Output Shaft from Mainshaft and Case

1. Place a new flywheel housing gasket on the front of the transmission case.
2. Place the flywheel housing on the six studs. Install the six nuts, bolts and lock washers. Tighten the nuts and bolts to specifications.
3. Install the clutch release mechanism in the flywheel housing.
4. Position the output shaft on the coupling gear and install the two flat keys and attaching bolts. Torque the bolts to specification and secure them with lock wire.
5. Install the rear bearing on the output shaft.
6. Position the bearing washer and the speedometer drive gear or spacer on the output shaft.
7. Position a new bearing cover gasket on the transmission case. Position the bearing cover on the case and install the attaching bolts. Torque the bolts to specification.

DESCRIPTION

TRANSMISSION

The RT-610 transmission features the twin countershaft principle of operation and is designed for medium-duty vehicles with engines in the 600 ft-lb maximum torque range.

Engine torque is split between the two countershafts, thus reducing tooth pressures on mainshaft and countershaft gears. This enables a reduction in gear, shaft and bearing size while maintaining a high capacity level.

Floating mainshaft gears are held in radial position by rotation of countershaft gears. Axial position is maintained by washers. This provides equal tooth loading on mainshaft gears and eliminates the need for sleeves and bushings.

Gears are clutched to the mainshaft by short sliding clutch gears on the mainshaft which engage internal splines in gear hubs. Sliding clutch gears, with conical clutching teeth, provide short and easy shifts.

Ten speeds are obtained by a five speed main section and a two speed range section. The five gear ratios in the main section are used once through reduction in low range and again in high (direct) range.

All ten speeds are controlled by one gear shift lever and a range control button. Range shifts are automatic after pre-selection.

REMOVAL AND INSTALLATION

GEAR SHIFT LEVER HOUSING

Removal

Remove the attaching capscrews and lift the gear shift lever housing or remote control housing from the shift bar housing (Fig. 1).

Installation

1. Make sure the shifting notches on bars in the shifting bar housing are aligned in the neutral position.
2. Install the gear shift lever housing on shifting bar housing, fitting lower end of lever into notches in shifting block and yokes (Fig. 1).
3. Install attaching capscrews, except capscrew at left-rear corner as this is used to secure air line.

FIG. 1 Removing Gear Shift Lever Housing

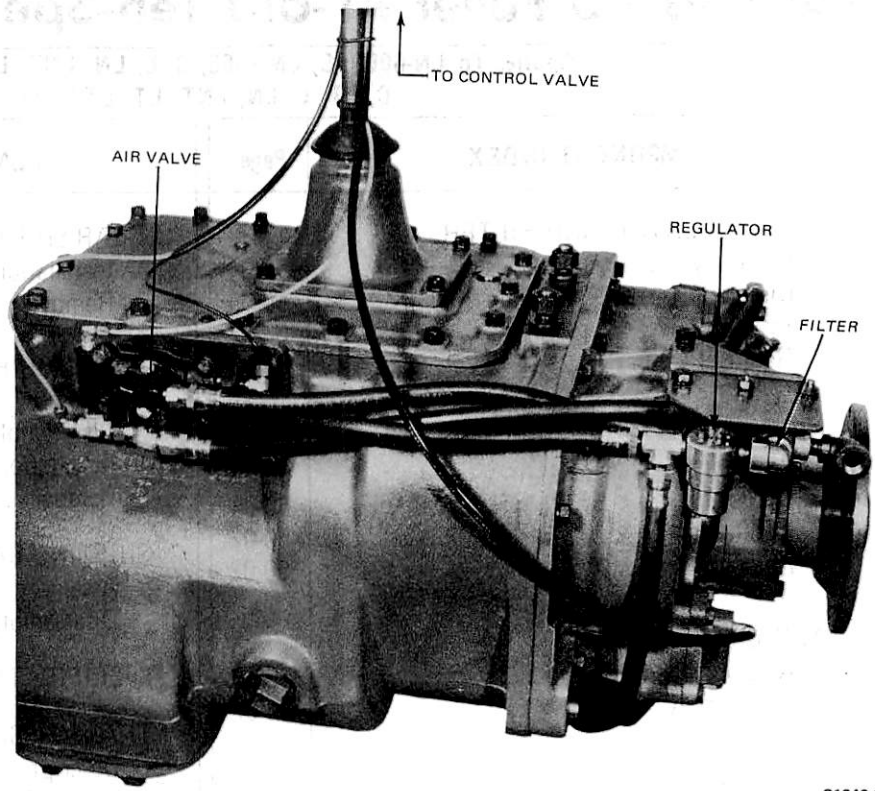

FIG. 2 Transmission Air System

AIR SHIFT CONTROLS

AIR VALVE

Removal

1. Remove the floor mat and the floor plate.
2. Place the gear shift lever in the neutral position. Drain the air from the system.
3. Disconnect the air line leading from the regulator to the tee fitting on the air valve (Fig. 2).
4. Disconnect the two air cylinder lines from the air valve.
5. Disconnect the two nylon air lines from the air valve.
6. Remove the air valve attaching bolts and remove the valve, gasket and the alignment sleeve.
7. Thoroughly clean the valve in cleaning solvent and dry it with compressed air.

Installation

1. Place the gear shift lever in the neutral position. The lever must remain in this position until air pressure has been admitted to the system.
2. Apply air pressure to the front port of the air valve to move the pistons to the rear. Failure to comply with these two steps may result in damage to the valve.
3. Position the alignment sleeve in the valve body.
4. Place a new gasket on the body.
5. Secure the body to the transmission with the attaching screws and lock washers. Tighten the screws to specification.
6. Connect all air lines to the valve as shown in Fig. 2.

RANGE SHIFT CONTROL VALVE

Removal

1. Drain the air from the system.
2. Disconnect the two nylon lines from the fittings.
3. Loosen the attaching clamp and remove the range shift control valve from the gear shift lever.

Installation

1. Secure the control valve to the gear shift lever with the attaching clamp. Make sure that the control valve button is six inches below the top surface of the gear shift knob when the button is pulled out. Tighten the clamp.
2. Connect the white nylon air line to the inlet port (right side) of the master control valve.
3. Connect the black nylon air line to the outlet port (left side).

AIR REGULATOR AND FILTER

Removal

1. Disconnect and remove the air line, including clamp, between the air valve and air regulator.
2. Remove street ell and reducer from regulator if necessary.
3. Remove capscrews and remove the air regulator and filter assembly from transmission.
4. Place in vise and turn the large hexagonal nut from threads of air regulator.
5. Remove the air regulator from nipple.
6. Remove the two capscrews and remove bracket from filter. The air filter contains a replaceable filter element which can be removed by turning out the bolt at top of filter and disengaging the body from cover.

Installation

1. Install nipple in output port of air filter.
2. Place the hexagonal nut and washer over nipple.
3. Place bracket over nipple and attach bracket to top of filter but do not tighten capscrews.
4. Replace the regulator on nipple.
5. Tighten the hexagonal nut on regulator to secure regulator to bracket, exhaust port away from transmission.
6. Tighten the two capscrews which attach the bracket to filter.
7. If previously removed, install bushing and 90 degree street ell in output port of air regulator. Street ell faces toward the gear shift lever housing when assembly is installed.
8. Install the air regulator and filter assembly on mounting surface on left side of transmission, tighten

capscrews securely.

9. Install air line between output port of air regulator and the tee in supply port of air valve. Fasten hose with clamp at left-rear capscrews location on gear shift lever housing.

TRANSMISSION

Removal

1. Bleed the air reservoir and disconnect the air line at the rear of the transmission.
2. Disconnect the drive shaft at the transmission companion flange.
3. Disconnect the speedometer cable at the transmission.
4. After cleaning the area around the cross-shaft housing, remove the housing and tie it out of the way. Cover the opening in the gear shift housing to prevent the entry of dirt.
5. Remove the shift control cable, speedometer cable and fuel line retaining clamps.
6. Disconnect the nylon cables at the air valve and shift cylinder.
7. Disconnect the clutch linkage at the clutch release arm.
8. Remove all but two of the clutch housing attaching bolts at the engine. Remove the dust cover from the bottom of the clutch housing.
9. Position a jack under the transmission. Raise the transmission slightly to relieve pressure at the side rail mounting brackets.
10. Remove the bolts that attach the transmission support to the frame side rail brackets. After removing the lock wire, remove the transmission support-to-transmission case bolts, washers, insulators and spacers. Remove the support.
11. After removing the remaining clutch housing attaching bolts, pull the transmission rearward to clear the input shaft.
12. Raise the truck to provide clearance in removing the transmission. Install safety stands, then remove the transmission from under the truck.

Installation

1. Place the transmission on a transmission jack (or chain hoist) and position the transmission input shaft in the clutch discs. As the input shaft enters the clutch, rotate the clutch release yoke so that the release yoke fingers contact the release bearing in their proper position. Be sure to position the clutch release bearing with the flat section on top.

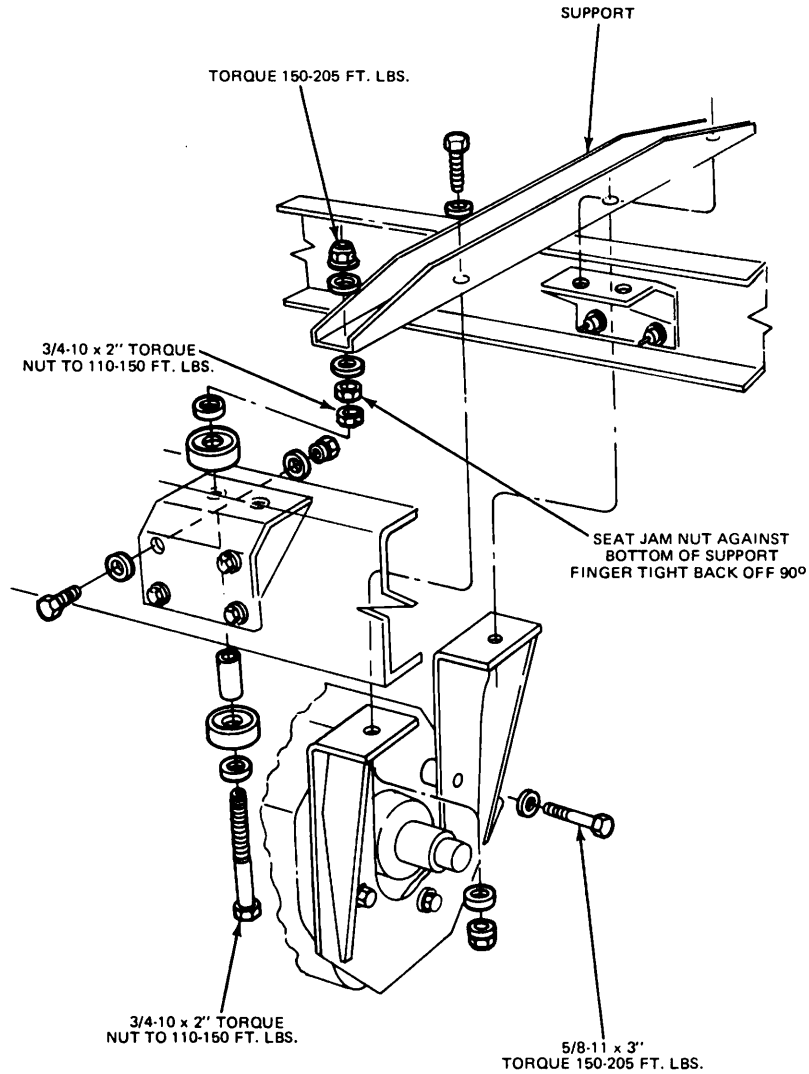

FIG. 3 Transmission Rear Support

2. Install the clutch housing attaching bolts and torque them to specification. Install the clutch housing dust cover. If this removal and installation involves the replacement of the pilot bearing also, the bearing must be pressed to approximately 1/16 inch beyond the flush position.
3. With proper support, position the transmission assembly for installation.
4. Position the support. Replace the spacers, insulators, washers and support-to-transmission case bolts. Secure with lock wire. Replace the support-to-frame side rail brackets bolts. (The transmission should be raised slightly to relieve pressure at the side rail mounting brackets).
5. Replace the dust cover at the bottom of the clutch housing. Replace the clutch housing attaching bolts. Torque to specifications.
6. Connect the nylon cables to the air valve and shift cylinder. Connect the speedometer cable and install the retaining clamps.
7. Install the shift control cable and fuel line retaining clamps.
8. Install the cross-shaft housing and torque the mounting bolts to specifications.
9. Connect the drive shaft and torque the bolts to specifications.
10. Lower the truck to the floor. Start the engine to build up air pressure and check for leaks.

DISASSEMBLY AND ASSEMBLY

GEAR SHIFT LEVER HOUSING

Disassembly

1. Remove the rubber dust protector from gear shift lever.
2. Mount the assembly in a vise with the large opening up.
3. Free the gear shift lever tension spring by twisting a heavy screwdriver between the spring and housing, forcing the spring from its seat under lugs cast in housing.
4. Remove the tension spring from housing.
5. Withdraw the tension spring washer and gear shift lever out through bottom of housing.
6. Remove the nut and lock washer from the gear shift lever pivot pin.
7. Remove pivot pin by forcing it inward and through wall of housing.

Assembly

1. Install the pivot pin in bore in housing, thread end outward.
2. Install the lock washer and nut on pivot pin.
3. Mount the housing in a soft-jawed vise with the large, bottom opening upwards.
4. Insert the gear shift lever in housing, fitting slot in pivot ball of shift lever on pivot pin.
5. Install the tension spring washer in housing.
6. Install the tension spring in housing, seating spring under lugs cast inside the housing.
7. Remove from vise and install the rubber dust protector over the gear shift lever and against neck of housing. (Do not install ball grip on lever until after the range control valve has been installed.)

AIR SHIFT CONTROLS

AIR VALVE

Disassembly

1. Remove all air line fittings and the vent from the valve.
2. Remove the two screws securing the side cap to the valve body and remove the cap (Fig. 4).
3. Remove the valve insert and spring from the piston. Remove the O-ring from the valve insert.
4. Remove the end cap and piston from the valve body. Remove the two O-rings from the piston.
5. Remove the nylon plug from the piston and remove the O-ring from the plug.

Assembly

1. Use all new O-rings and lubricate them with a thin film of vaseline before installing them.
2. Install O-rings on the piston and nylon plug. Install the plug in the piston (Fig. 4).
3. Insert the piston in the valve body and install the end cap. Tighten the cap securely.
4. Install the spring into the piston.
5. Install an O-ring on the valve insert and install it in the piston.
6. Secure the side cap to the valve body with the attaching screws and lock washers. Tighten the screws securely.
7. Coat the fittings with sealer and install them in their respective ports. Install the vent in the body.

RANGE SHIFT CONTROL VALVE

Disassembly

1. Place the control valve with the rear housing (outlet side) on a bench. Remove the front and rear housing attaching bolts.
2. Remove the control button and plunger assembly (Fig. 5).
3. Remove the detent balls, springs and felt seals from the valve housings.
4. Remove the valve plate and O-ring from the rear housing.
5. Lift the valve insert from the front housing and remove the O-ring.
6. Remove the wave washer installed under the valve insert.
7. If necessary, drive the roll pin from the button with a punch, then remove the control button from the plunger.

Assembly

1. Insert the wave washer in the front housing bore (Fig. 5).
2. Install a new O-ring on the valve insert and install the insert into the front housing.
3. Position a new O-ring into the rear housing bore and install the valve plate.
4. Install a felt seal into the top of each housing.
5. If the control button was removed, secure it to the plunger with the roll pin.
6. Position the detent balls and springs into the housings and install the control button and plunger assembly. Install the housing attaching screws.

AIR REGULATOR AND FILTER

Disassembly

1. With regulator in a vise with the **in surface and end cap between jaws of vise, turn lock ring from regulator body.**
2. Slowly open vise and remove loose parts, consisting of spring plate, spring, shims and spring retainer (Fig. 6).
3. Remove diaphragm from body.
4. Remove snap ring, washer and piston spring from piston.
5. Push piston out through air port.
6. Remove seal from bore in body.

Assembly

1. Replace seal in bore in body.
2. Replace piston, applying Lubriplate (Fig. 6).
3. Replace piston spring, washer and snap ring on piston.
4. Replace diaphragm in body.
5. Replace the spring retainer, shims, spring and spring plate.
6. Replace the lock ring on the regulator body.

MAIN TRANSMISSION

Disassembly

Refer to Auxiliary Section for instructions on separating the main and auxiliary sections of the transmission.

1. Remove right countershaft snap ring from rear bearing bore of case (Fig. 7). Using soft bar and maul against rear of countershaft, move the assembly forward as far as possible until snap ring groove in front of bearing is exposed. If front bearing snap ring groove can not be exposed (due to variances in thickness of case), use punch between hub of countershaft drive gear and inner race of bearing to move the gear forward on shaft.
2. Install snap ring in the exposed bearing snap ring groove. (Use snap ring which was removed from rear bearing bore.) Loosen the capscrews at the bearing retaining rings on auxiliary drive gear. This will allow movement to he rear of the countershaft and mainshaft assemblies.
3. Using soft bar and maul against front of countershaft, move the countershaft assembly to the rear as far as possible. This will move front bearing forward on shaft. Using soft bar and maul against rear of countershaft, again move the

countershaft as far forward as possible to unseat front bearing from case bore. Use puller or pry bars to remove front bearing.
4. Use curved soft bar and maul from inside case to move the rear countershaft bearing to the rear far enough to expose snap ring groove in rear bearing. Install snap ring in groove in rear bearing (same snap ring as used on front bearing), and use pullers or pry bars to remove countershaft rear bearing.
5. Move the drive gear and shaft forward as far as possible.
6. Remove the bearing retaining snap ring from groove in shaft.
7. Hold shaft in position and tap the drive gear forward to unseat bearing from case.
8. Use pullers or pry bars to complete removal of bearing.
9. Remove the drive gear washer.
10. Remove the snap ring from groove in ID of drive gear.
11. Pull shaft forward and from splines of drive gear.
12. If necessary, remove bushing from pocket in clutch shaft.
13. Move the drive gear to the rear and against the 4th speed gear, engaging teeth of sliding clutch gear.
14. Remove capscrews and remove the two bearing retainer rings from case.
15. Remove the coupling snap ring from the groove in mainshaft (located in bore of auxiliary drive gear).
16. Tap against front of mainshaft to move the auxiliary drive gear bearing to the rear, exposing the bearing snap ring.
17. Use pry bars to remove the auxiliary drive gear assembly from case bore and from splines of mainshaft.
18. Remove snap ring from groove in auxiliary drive gear.
19. Press or use driver to remove bearing from auxiliary drive gear.
20. Use curved pry bar to walk bearing from idler bore in case.
21. Remove the rear idler washer and holder from bore. (If necessary, bend holder lugs and remove washer from holder.)
22. Remove reverse idler gear from case.
23. Remove the idler bearing from reverse idler gear.
24. Remove the front idler washer from case.
25. Block the right countershaft to the right as far as possible and lift the mainshaft assembly from case.
26. Remove the drive gear and the 4th-5th sliding clutch from mainshaft.
27. Inside hub of the 4th speed gear, remove snap ring from groove in mainshaft (Fig. 8).
28. Remove the 4th speed gear and washer.
29. Remove the 3rd speed gear and washer.
30. Remove the 2nd-3rd speed sliding clutch.
31. Remove the long key from slot in mainshaft.
32. Remove the 2nd speed gear and washer.
33. Remove the 1st speed gear and washer.
34. Remove the 1st-reverse sliding clutch.
35. Remove the reverse gear and washer.
36. Lift the right countershaft from case.
37. Remove bearings from the left countershaft in the same manner in which bearings were removed from right countershaft.
38. Lift the left countershaft from case.

Both countershafts are disassembled in the same manner as construction is identical.

39. Remove snap ring from front of countershaft (Fig. 9).
40. Press the drive gear from shaft.
41. Press the 4th speed gear from shaft.
42. Using the rear face of the **PTO** gear as a base in press, press the 3rd speed gear, and the **PTO** -2nd speed gear cluster from shaft. If necessary, remove Woodruff key, long key and roll pin from shaft.
43. Use curved pry bar to walk right reverse idler gear bearing from idler bore in case.
44. Remove the rear idler washer and holder from bore. If necessary, bend holder lugs and remove washer from holder.
45. Remove the reverse idler gear from case.
46. Remove the idler bearing from reverse idler gear.
47. Remove the front idler washer from case.

Assembly

1. Install the small, flat right reverse-idler gear front washer on pin in lower right of case.
2. Set reverse gear in position next to washer, long hub to the rear.
3. Install needle bearing through rear bore and into hub of reverse gear.
4. Place rear washer in holder if previously removed, oil slot down, and bend lugs to secure washer.
5. Place washer and holder into reverse gear case bore, oil slots toward gear, holder flange to the rear.
6. Install the auxiliary countershaft front bearing into the reverse gear case bore to hold the reverse idler gear assembly in position.

The front portion of the auxiliary countershaft is used as a journal for the reverse idler gear.

Countershafts are identical and are assembled in the same manner.

7. If previously removed, install roll pin, long key and Woodruff key in slots in countershaft (Fig. 10).
8. Press the **PTO** -2nd speed gear cluster on countershaft, **PTO** gear to the front.
9. Press the 3rd speed gear on shaft, long hub to the rear.
10. Press the 4th speed gear on shaft, long hub to the front.
11. Press drive gear on shaft, long hub to the rear.
12. Install snap ring in groove at front of shaft (Fig. 11).
13. On the drive gear of each countershaft mark the gear tooth which is aligned with the keyway in shaft. This tooth will be stamped with an O (Fig. 12).
14. Place the left countershaft into position in case—do not install bearings.
15. Place the right countershaft into position in case—do not install bearings.
16. Place the mainshaft in vise with pilot end down. Keep keyway free for insertion of long key.

Each mainshaft gear is held in position by locking the gear splined washer to the mainshaft with key. There is one splined washer for each gear. Splined washers for the reverse, 1st, 2nd, and 3rd speed gears are identical; the 4th speed gear splined washer is of smaller diameter.

17. Install the second speed gear washer at second speed gear location, inserting key from bottom to lock washer in position.
18. Install the second speed gear on splined washer, clutching teeth down.
19. Install the first speed gear on shaft and against second speed gear, clutching teeth up.
20. Insert splined washer in hub of first speed gear. Align washer with mainshaft splines and move key up to lock washer in position.
21. Install the 1st-reverse sliding clutch, aligning slot in clutch with key.
22. Install the reverse gear splined washer, align keyway and lock with key.
23. Reposition assembly in vise with the pilot end up.
24. Install the 2nd-3rd speed sliding clutch, aligning keyway in sliding clutch with key in shaft.
25. Install the 3rd speed gear splined

washer; lift key to install washer under pin in key to lock in position.
26. Install the 3rd speed gear on mainshaft, fitting gear splines on those of washer (Fig. 13).
27. Install the 4th speed gear on mainshaft (clutching teeth up) and against 3rd speed gear.
28. Install the 4th speed gear splined washer on mainshaft and in hub of 4th speed gear.
29. Install snap ring in groove in mainshaft which will hold the 4th speed gear in position on shaft.
30. Install the 4th-5th speed sliding clutch on mainshaft, place in engagement with 4th speed gear.
31. **Mark timing teeth on drive gear (5th speed gear).**

Mark two adjacent teeth on drive gear. Mark the two adjacent teeth on drive gear which are directly opposite the first set marked. There should be the same number of teeth between markings on each side of gear.

32. Install the drive gear on mainshaft and against the 4th speed gear, snap ring groove in drive gear to the front.
33. Remove the assembly from vise and install the reverse gear on rear of mainshaft, engaging splines of gear with those of splined washer on mainshaft.
34. Move both countershafts toward case wall as far as possible.
35. Place the mainshaft assembly in position in case; block under front of mainshaft to center in front bore of case.
36. Press bearing on auxiliary drive gear, snap ring towards gear.
37. Install bearing retaining snap ring in groove of auxiliary drive gear shoulder.
38. Center mainshaft in rear bore of case and install auxiliary drive gear on splines of mainshaft.
39. Seat auxiliary drive gear bearing in rear bore of case.
40. In hub of auxiliary drive gear, install the coupling snap ring in groove in mainshaft.
41. Install the two bearing retainer plates on case.
42. Attach both upper and lower plates, using a double locking lug for each plate. Tighten capscrews securely and secure by bending locking lugs.
43. If previously removed, install bushing in pocket of clutch shaft; install flush with shaft, making sure that oil hole in shaft is not plugged.
44. Install the clutch shaft in splines of drive gear, moving gear forward against inside wall of case.
45. Install ring in groove in I.D. of drive gear.
46. Install the drive gear spacer on shaft.
47. Install the drive gear bearing on shaft and into case bore.
48. Install bearing retaining snap ring in groove in clutch shaft, taper to the outside.
49. Place the left countershaft into mesh with mainshaft gears, placing the marked timing tooth on countershaft drive gear into proper mesh with the two marked timing teeth on main drive gear.
50. Hold left countershaft in position and install front and rear bearings. Center rear of left countershaft in rear bore of case with wood block. Partially install front bearing on countershaft and in case bore. Partially install rear bearing on countershaft and in case bore. Use flanged bearing driver to complete seating both front and rear bearings.
51. Install snap ring in groove in rear bore of case.
52. Place the right countershaft into mesh with mainshaft gears, placing the marked timing tooth on countershaft drive gear into proper mesh with the two marked timing teeth on main drive gear (Fig. 14).
53. Hold right countershaft in position and install front and rear bearings in the same manner as installed on left countershaft.
54. Install snap ring in groove in rear bore of case.
55. Install the left reverse-idler gear front washer on pin in upper left of case.
56. Install needle bearing in hub of reverse-idler gear.
57. Set reverse-idler gear in position, long hub to the rear.
58. Place rear washer in holder if previously removed, oil slot down, and bend lugs to secure washer.
59. Place washer and holder into reverse gear case bore, oil slots toward gear, holder flange to the rear.
60. Install the auxiliary countershaft front bearing into the reverse-gear case bore to hold the reverse idler gear assembly in position.

The front portion of the auxiliary countershaft is used as a journal for the reverse idler gear.

MAIN TRANSMISSION SUB-ASSEMBLIES

SHIFTING BAR HOUSING

Disassembly

1. Remove the shifting bar housing from the transmission.
2. Remove the two capscrews retaining the tension spring cover and remove the cover from the housing.
3. Tilt the housing and remove the tension springs and balls from the bores in the top of the housing.
4. Set the housing in a vise with the plunger side up.
5. Cut the lock wires and remove the lock screws from each shifter shaft prior to its removal.
6. Move the top and center shifter shafts to the rear and out of the housing. Remove the shifting fork from each shaft. As the neutral detent in the center shaft clears the housing boss, remove the interlock pin (Fig. 15).
7. Remove the actuating plunger from the bore in the housing.
8. Move the lower shifter shaft to the rear and out of the housing. Remove the shifting fork from the shaft. **Do not lose the interlock balls as the lower shaft is removed.**

Assembly

Install the shifter shaft through the rear bores of the housing with the neutral detent notches to the rear. Keep the shafts in the neutral position when installed.

1. Place the housing in a vise with the plunger side up.
2. Install the first and reverse-speed shifter shaft in the bottom bore and through the shifting fork. Install the set screw and secure with lock wire.
3. Install the actuating plunger in the front opening of the housing and a three-quarter inch interlock ball in the rear opening.
4. Position the second and third-speed shifter shaft in the center bore and through the shift block and fork. **Be sure to install the interlock pin in the bore at the neutral notch (Fig. 15). Install the set screws and secure with lock wire. Keep the shifter shaft so that the interlock pin remains in a vertical position during the completion of the assembly. Rotating the shaft will cause the interlock pin to jam into the tension spring bores.**
5. Install a three-quarter inch ball in the rear opening of the housing.
6. Position the fourth and fifth-speed shifter shaft in the upper bore and through the shifting block and fork. Install the set screws and secure with lock wire.
7. Remove the gear shift housing from the vise and place it on a work bench. Install the three detent balls and springs into the top of the housing.

AUXILIARY TRANSMISSION

SEPARATION OF MAIN AND AUXILIARY SECTIONS

1. Disconnect the two nylon air lines at air valve on transmission.
2. Remove the gear shift lever housing lever and control valve as a unit by turning out the four attaching capscrews.
3. Disconnect and remove the air line, including clamp, between the air valve and air regulator.
4. Remove street ell and reducer from regulator if necessary.
5. Remove capscrews and remove the air regulator and filter assembly.
6. Remove the two air lines between the air valve and air cylinder in auxiliary.
7. Remove the four capscrews and remove the air valve from transmission. If necessary, remove fittings from air valve.
8. Remove the actuating spring and pin from bore in transmission.
9. Remove the attaching capscrews and lift the gear shift lever housing or remove control housing from the shift bar housing.
10. Remove the attaching capscrews, jar to break gasket seal and lift the shifting bar housing from transmission.
11. Lock the transmission by engaging two speeds with the mainshaft sliding clutch gears. Remove elastic stop nut from output shaft. Pull flange or yoke straight to the rear and off shaft.
12. Remove capscrews that attach main and auxiliary sections. Insert puller screws in auxiliary housing flange. Tighten puller screws evenly to move auxiliary section straight to the rear and from front section (Fig. 16).
13. Remove the clutch release mechanism if so equipped. Turn nuts from the six studs and turn out the two bolts which attach clutch housing to case. Break gasket seal and remove clutch housing from case.
14. Remove capscrews and remove the front gear cover. (Tap against drive gear from inside case to break gasket seal).

JOINING OF MAIN AND AUXILIARY SECTIONS

1. Install the drive gear bearing cover.
2. Install the clutch housing, attaching securely with the six nuts and two bolts.
3. If so equipped, install the clutch release mechanism.

The two reverse gears, including the washers, must be in perfect alignment with center of case bores as the front of the auxiliary countershafts must be inserted in these parts during auxiliary installation. A heavy grease or Lubriplate will help hold washers in place. Also check rear of front section to make sure all snap rings have been installed.

4. Install auxiliary section on front section, aligning auxiliary section on dowel pins and the extended portion of auxiliary countershafts with reverse idler gears. It may make assembly easier if someone slowly rotates clutch shaft during installation.

The auxiliary can also be installed with front section in a vertical position. Place clutch housing on blocks and use chain hoist to lower auxiliary section into position.

5. Secure the auxiliary with attaching capscrews.
6. Lock transmission by engaging two gears with the mainshaft sliding clutches.
7. Make sure the speedometer gear washer and the speedometer gear or replacement spacer are installed on tailshaft.
8. Install the companion flange on splines of tailshaft. Install the companion flange nut. Tighten securely, using the correct torque rating.
9. Make sure the shift bars are in the neutral position. Place the sliding clutches on the mainshaft in the neutral position.
10. Install the shifting bar housing on transmission, fitting yokes into yoke slots of corresponding clutch gears. Install the attaching capscrews, tighten securely.
11. Make sure the shifting notches on bars in the shifting bar housing are aligned in the neutral position.
12. Install the gear shift lever housing on shifting bar housing, fitting lower end of lever into notches in shifting block and yokes.
13. Install attaching capscrews, except capscrew at left-rear corner as this is used to secure air line.
14. If previously removed, install fittings on air valve.
15. Install the actuating pin and spring in bore in transmission.
16. Make sure the alignment sleeve is installed in air valve.

Before installing alignment sleeve, check bore in air valve to make sure the piston is either in a forward or rear position. Piston can be moved with air or pencil.

17. Install the air valve on transmission, tighten capscrews evenly and securely. Actuating plunger in case fits into alignment sleeve in air valve.
18. Install fittings in shift cylinder, if previously removed. This consists of two 90 degree street ells.
19. Install the high range air line between the air port in the rear cover of the air cylinder and the side rear port of the air valve.
20. Install the low range air line from air port in top of cylinder to the side air port in air valve. This is the side port which is towards the front of the transmission and constant supply of air valve.
21. Tighten the hexagonal nut on regulator to secure regulator to bracket, exhaust port away from transmission.
22. Tighten the two capscrews which attach the bracket to filter.
23. If previously removed, install bushing and 90 degree street ell in output port of air regulator. Street ell faces toward the gear shift lever housing when assembly is installed.
24. Install the air regulator and filter assembly on mounting surface on left side of transmission, tighten capscrews securely.
25. Install air line between output port of air regulator and the tee in supply port of air valve. Fasten hose with clamp at left-rear capscrews location on gear shift lever housing.
26. Replace the gear shift lever housing lever and control valve. Tighten the four attaching capscrews.
27. Install the black nylon air line from the **OUT** port of control valve to the air port in hexagonal end cap of air valve.
28. Install the white nylon air line from the **IN** port of control valve to the tee in supply port of air valve.

DISASSEMBLY OF AUXILIARY SECTION

1. Use pullers to remove bearing from front of tailshaft.
2. Turn out capscrews and remove the rear bearing cover.
3. If necessary, remove the rear seal from cover.
4. Remove the speedometer gear or replacement spacer from tailshaft.
5. Remove the speedometer gear washer.
6. Remove inside housing, use long punch to move outer races of countershaft rear bearings to the rear; move races approximately one-half inch (Fig. 17).
7. Pull the countershafts forward and out of housing.
8. Pull bearing inner race from rear of countershaft (Fig. 18).

9. Remove snap ring from groove in front of shaft.
10. Press the drive gear forward and from shaft. If necessary, remove key from countershaft.
11. Remove capscrews and remove the air cylinder cover.
12. Remove the nut and lock washer from air cylinder piston shaft.
13. Use air to remove piston (Fig. 19).
14. If necessary, remove O-ring from OD of piston.
15. Remove the copper seal from shaft.
16. Move the synchronizer assembly, shift yoke, and piston shaft forward and out of housing as a complete assembly.
17. Remove the shaft and yoke from synchronizer assembly.
18. Cut lock wire, turn out the two lock screws and remove yoke from shaft.
19. Place the larger low range synchronizer ring on bench.
20. Turn and pull upward to remove the high range synchronizer from pins (Fig. 20).

There are three springs located in housing of high range synchronizer which will be released as high range synchronizer is removed from pins.

21. Remove the sliding clutch from low range synchronizer pins.
22. Remove the dust seal, and air port extension from top of housing (Fig. 21).
23. Remove air cylinder from housing.
24. Remove O-ring from small bore in cylinder, if necessary.
25. Drive or press against rear of tailshaft to move low speed gear and tailshaft assembly forward and from rear bearing (Fig. 22).
26. Remove the rear washer and the low speed gear from rear of shaft.
27. Remove spline washer from hub of low speed gear.
28. Move the mainshaft rear bearing to the rear and out of housing.
29. Use bearing driver to remove the countershaft rear bearings from housing.

ASSEMBLY OF AUXILIARY SECTION

1. Make sure magnetic cleaner is installed in recess in auxiliary case.
2. Mark timing teeth on the low speed gear.

Mark any two adjacent gear teeth on low speed gear. Then, mark the two adjacent teeth which are directly opposite the first set marked. There should be the same number of teeth between the markings on each side of the gear.

3. Place splined spacer in hub of low speed gear, shoulder toward rear.
4. Install the low speed gear and spacer over rear of shaft and against

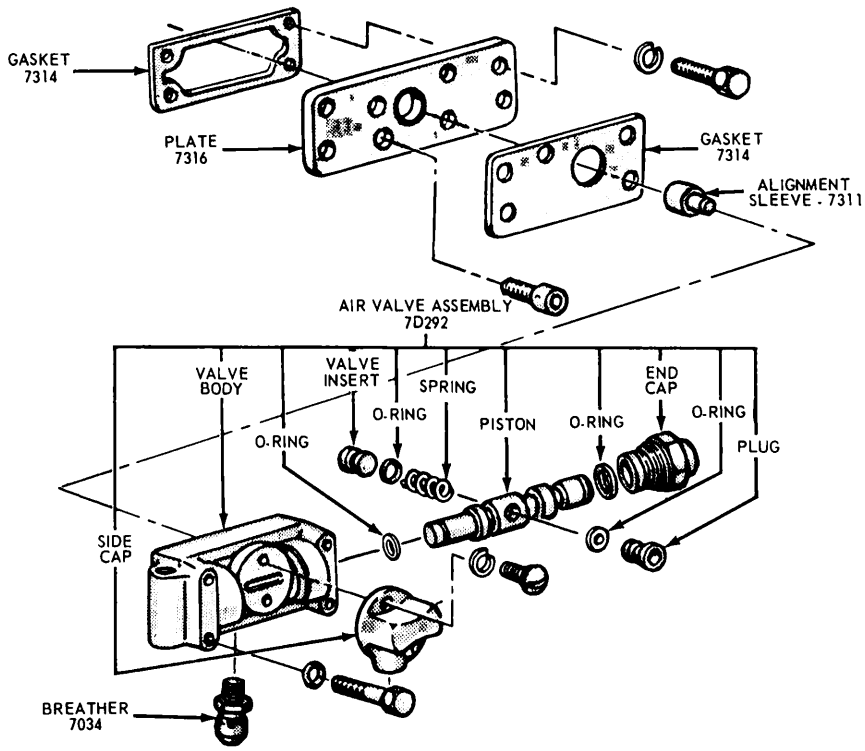

FIG. 4 Air Valve Disassembled

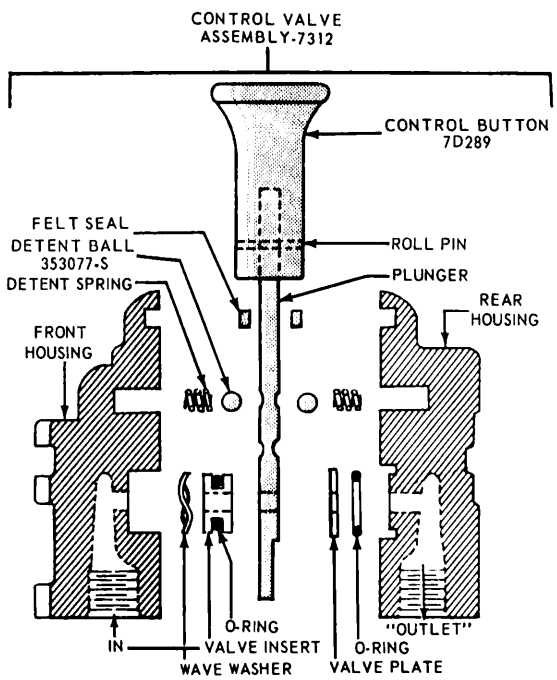

FIG. 5 Range Shift Control Valve—Disassembled

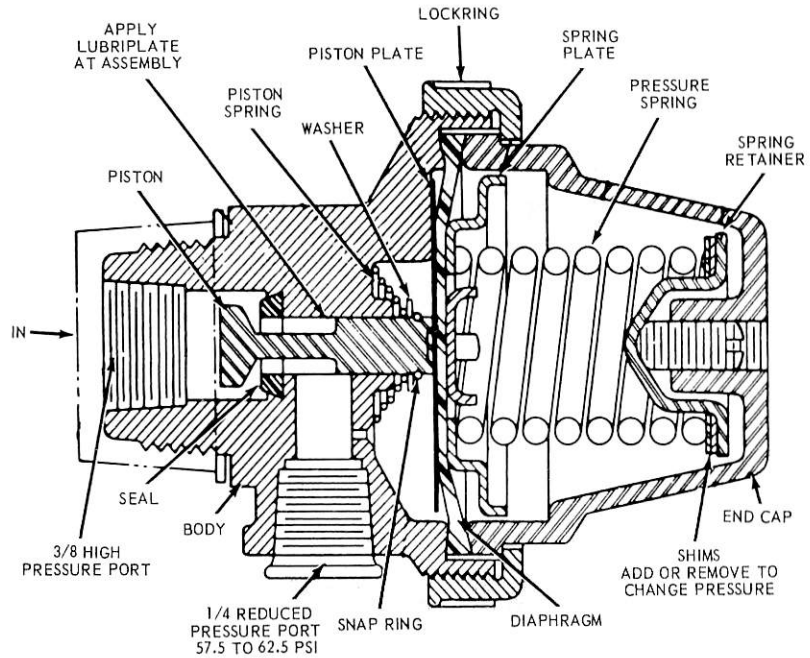

FIG. 6 Air Regulator—Sectional View

shoulder, clutching teeth to the front.

5. Install the low speed gear rear washer on shaft and against gear, chamfer to the rear.
6. Set the tailshaft with the forward end down and place auxiliary housing over rear of shaft so that shaft extends through rear bore.
7. Seat mainshaft rear bearing securely on shaft and in bore.
8. Install O-ring in slot in small bore in range shift air cylinder.
9. Install cylinder in housing with small bore in cylinder aligned with air port in top of auxiliary.
10. Install dust cover and air port extension through housing and into bore of air cylinder.
11. Place the shifting yoke on piston shaft, fork towards thread end.
12. Align slots in shaft with bores in yoke hub and install the two lock screws. Secure with safety wire.
13. Place yoke in slot of sliding clutch; thread end of piston shaft is towards the larger low range synchronizer.
14. Place the entire assembly into auxiliary housing, threading splined sliding clutch on tailshaft and inserting piston shaft through cylinder bore.
15. Install copper seal on thread end of piston shaft.
16. Install O-ring on OD of piston.
17. Install piston on shaft and against copper washer, flat side of piston out.
18. Install lock washer and nut on shaft to secure piston.
19. Install gasket and cylinder cover. Tighten the four capscrews securely.
20. Place the larger low range synchronizer ring face down on bench with pins up.
21. Place the sliding clutch, recessed side up, on pins of low range synchronizer.
22. Install the three springs in bores in high range synchronizer ring (Fig. 23).
23. Place the high range synchronizer ring over pins of the low speed synchronizer ring, seating springs against pins.
24. Apply pressure to high range synchronizer ring to compress springs and seat pins of low range synchronizer fully into bores of high range synchronizer ring.
25. If previously removed, install keys in keyways in countershafts.
26. Press drive gear on each countershaft, long hub to the rear.
27. Install snap ring in front of each countershaft.
28. Install bearing inner race on rear of each countershaft.
29. **To mark countershaft gear teeth for timing: Mark the tooth on the countershaft low speed gear which is aligned with the keyway in drive gear. This gear tooth will be stamped with an O (Fig. 24).**
30. Seat the outer races of the countershaft rear bearings only partially in bores, just far enough to stay in place.
31. Place countershafts into position in auxiliary housing, inserting inner races into the partially installed outer races.

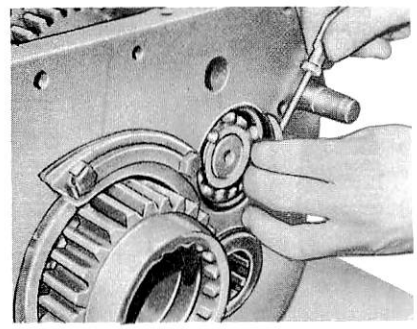

FIG. 7 Removing Right Countershaft Snap Ring

Timing countershaft gears with low speed gears: As the countershafts are installed, mesh the marked low speed gear tooth on each countershaft between each set of marked gear teeth on the low speed gear.

32. With countershafts in position, complete the installation of the countershaft rear bearings on shaft and into case bore. Seat securely.
33. Install the speedometer gear rear washer on tailshaft and against bearing, chamfered ID towards bearing, and install the speedometer gear or replacement spacer on shaft and against washer. If previously removed, install oil seal in rear bearing cover, lip of seal to the rear.
34. Install the rear bearing cover with the speedometer bore up and to the left, tighten capscrews securely. Install bearing on front of tailshaft.

DESCRIPTION

TRANSMISSION

Models RT and RTO-910 consists of two sections; a five-speed transmission with closely spaced ratios, and a two-speed auxiliary with wider spaced ratios.

Both models are a twin countershaft design, which splits torque equally between the two shafts, providing a high torque capacity to weight ratio. Because of torque splitting, each gear set carries only half the load, greatly reducing the face width of each gear. The mainshaft gears when not engaged float between the countershaft gears, eliminating the need for gear sleeves and bushings. All gears are in constant mesh and have spur type teeth (Fig. 1).

ADJUSTMENTS

GEAR SHIFT LINKAGE—W-SERIES

1. Place the gear shift lever in the neutral position.
2. Loosen the bolts on the shift rod turnbuckle (Fig. 2). Then, rotate the turnbuckle until the rear of the shift knob is located 10 to 10 1/2 inches from the front face of the instrument panel. Torque the lower turnbuckle bolt.
3. While holding the rear cross-shaft lever in the extreme right position, move the gear shift lever (in neutral) until the outside edge of the shift knob is 2 29/32-3 13/32 inches from the console edge. Torque the upper turnbuckle bolt.
4. Check the operation of the gear shift lever in all positions and readjust if necessary.

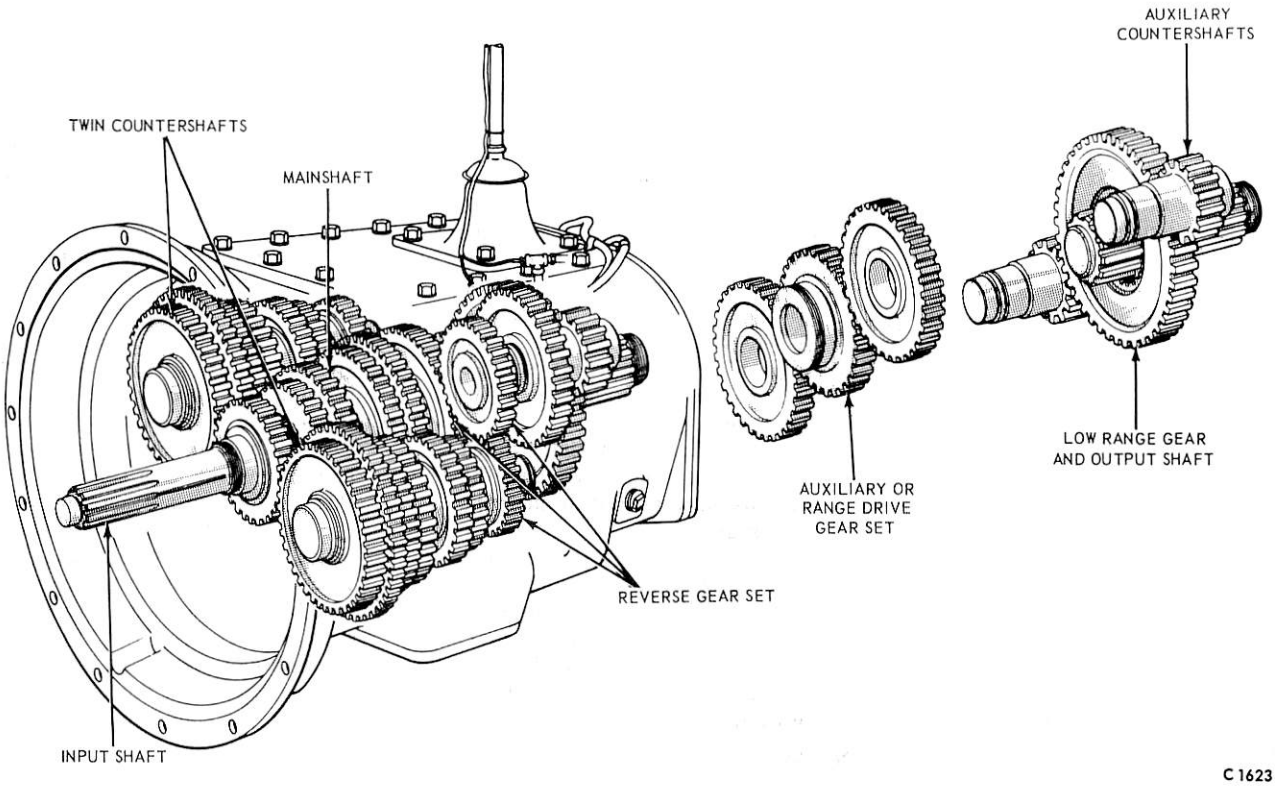

FIG. 1 10-Speed Transmission—Fuller RT and RTO-910

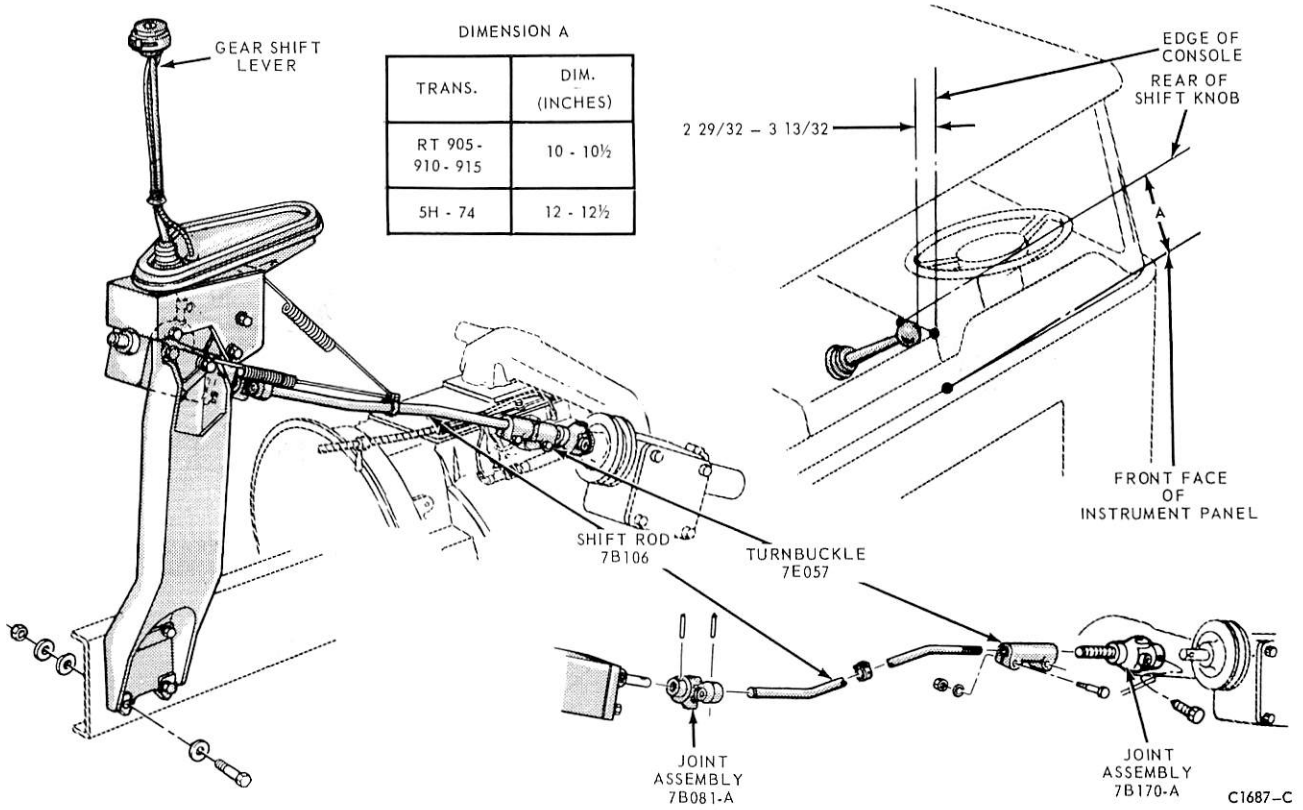

FIG. 2 Gear Shift Linkage Adjustments—W-Series

REMOVAL AND INSTALLATION

TRANSMISSION ASSEMBLY

REMOVAL

1. Bleed the air reservoir and disconnect the air line at the rear of the transmission.
2. Disconnect the drive shaft at the transmission compantion flange.
3. Disconnect the speedometer cable at the transmission.
4. After cleaning the area around the cross-shaft housing, remove the housing and tie it out of the way. Cover the opening in the gear shift housing to prevent the entry of dirt.
5. Remove the shift control cable, speedometer cable and fuel line retaining clamps.
6. Disconnect the nylon cables at the air valve and shift cylinder.
7. Disconnect the clutch linkage at the clutch release arm.
8. Remove all but two of the clutch housing attaching bolts at the engine. Remove the dust cover from the bottom of the clutch housing.
9. Position a jack under the transmission, and raise the transmission slightly to relieve pressure at the side rail mounting brackets.
10. Remove the bolts that attach the transmission support to the frame side rail brackets (Fig. 3). After removing the lock wire, remove the transmission support-to-transmission case bolts, washers, insulators, and spacers and remove the support.
11. Attach a chain hoist to the transmission if working on a W-Series truck.
12. **After removing the remaining clutch housing attaching bolts, pull the transmission rearward to clear the input shaft.**
13. Raise the truck to provide clearance in removing the transmission. Install safety stands, and then remove the transmission from under the truck. **On a W-Series truck, the transmission must be lifted out rather than lowered.**

INSTALLATION

1. Place the transmission on a transmission jack (or chain hoist) and position the transmission input shaft in the clutch discs. As the input shaft enters the clutch, rotate the clutch release yoke so that the release yoke fingers contact the release bearing in their proper position. Be sure to position the clutch release bearing with *the flat* section on top.
2. Install the clutch housing attaching bolts and torque them to specifications. Install the clutch housing dust cover.
3. If working on a W-Series truck, support the transmission with a jack and remove the hoist chains.
4. Position the transmission support to the frame side rail brackets and install the attaching bolts (Fig. 3).
5. Install the support-to-transmission case bolts, washers, insulators, and spacers. Torque the bolts to specifications and secure them with lock wire. Remove the jack.
6. Connect the clutch linkage to the clutch release arm.
7. Connect the nylon cables to the air valve and shift cylinder. Connect the speedometer cable and install the retaining clamps.

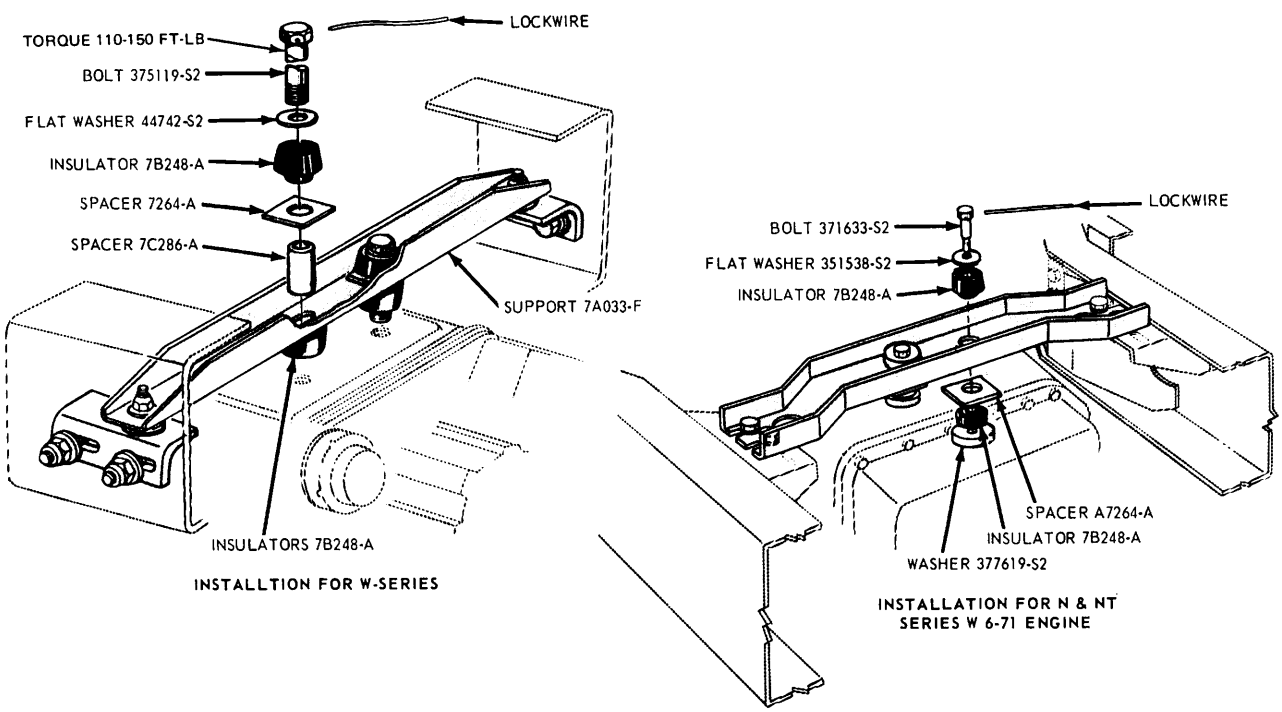

FIG. 3 Transmission Rear Support

8. Install the shift control cable and fuel line retaining clamps.
9. Install the cross-shaft housing, and torque the mounting bolts to specifications.
10. Connect the drive shaft and torque the bolts to specifications.
11. Lower the truck to the floor. Start the engine to build up air pressure, and check for leaks.

DISASSEMBLY AND ASSEMBLY

AIR SHIFT CONTROLS

AIR VALVE

Disassembly

1. Remove the floor mat and the floor plate.
2. Place the gear shift lever in the neutral position. Drain the air from the system.
3. Disconnect the air line leading from the regulator to the fitting on the air valve (Fig. 4).
4. Disconnect the two air cylinder lines from the air valve.
5. Disconnect the two nylon air lines from the air valve.
6. Remove the air valve attaching bolts and remove the valve gasket, and the alignment sleeve (Fig. 5).
7. Thoroughly clean the valve in cleaning solvent and dry it with compressed air.
8. Remove all air line fittings and the vent from the valve.
9. Remove the two screws securing the side cap to the valve body and remove the cap (Fig. 5).
10. Remove the valve insert and spring from the piston. Remove the O-ring from the valve insert.
11. Remove the end cap and piston from the valve body. Remove the two O-rings from the piston.
12. Remove the nylon plug from the piston and remove the O-ring from the plug.

Assembly

1. Use all new O-rings and lubricate them with a thin film of vaseline before installing them.
2. Install O-rings on the piston and nylon plug. Install the plug in the piston (Fig. 5).
3. Insert the piston in the valve body and install the end cap. Tighten the cap securely.
4. Install the spring into the piston.
5. Install an O-ring on the valve insert and install it in the piston.
6. Secure the side cap to the valve body with the attaching screws and lock washers. Tighten the screws securely.

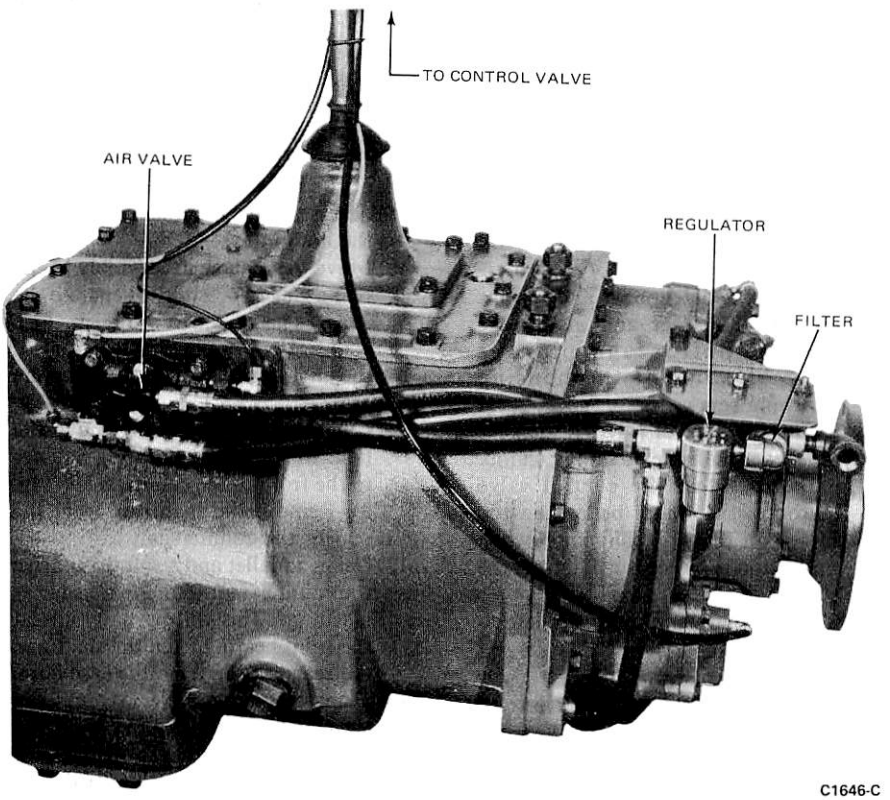

FIG. 4 Transmission Air System

7. Coat the fittings with sealer and install them in their respective ports. Install the vent in the body.
8. Place the gear shift lever in the neutral position. The lever must remain in this position until air pressure has been admitted to the system.
9. Apply air pressure to the front port of the air valve to move the pistons to the rear. Failure to comply with these two steps may result in damage to the valve.
10. Position the alignment sleeve in the valve body.
11. Place a new gasket on the body.
12. Secure the body to the transmission with the attaching screws and lock washers. Tighten the screws to specification.
13. Connect all air lines to the valve as shown in Fig. 4.

MASTER CONTROL VALVE

Disassembly

1. Drain the air from the system.
2. Disconnect the two nylon lines from the fittings.
3. Loosen the attaching clamp and remove the master control valve from the gear shift lever.
4. Place the control valve with the rear housing (outlet side) on a bench, and remove the front and rear housing attaching bolts.
5. Remove the control button and plunger assembly (Fig. 6).
6. Remove the detent balls, springs, and felt seals from the valve housings.

7. Remove the valve plate and O-ring from the rear housing.
8. Lift the valve insert from the front housing, and remove the O-ring.
9. Remove the wave washer installed under the valve insert.
10. If necessary, drive the roll pin from the button with a punch then remove the control button from the plunger.

Assembly

1. Insert the wave washer in the front housing bore (Fig. 6).
2. Install a new O-ring on the valve insert and install the insert into the front housing.
3. Position a new O-ring into the rear housing bore and install the valve plate.
4. Install a felt seal into the top of each housing.
5. If the control button was removed, secure it to the plunger with the roll pin.
6. Position the detent balls and springs into the housings and install the control button and plunger assembly, install the housing attaching screws.
7. Secure the control valve to the gear shift lever with the attaching clamp. Make sure that the control valve button is six inches below the top surface of the gear shift knob when the button is pulled out. Tighten the clamp.
8. Connect the white nylon air line to the inlet port (right side) of the master control valve.
9. Connect the black nylon air line to the outlet port (left side).

MAIN TRANSMISSION

Refer to Auxiliary Section for instructions on separating the main and auxiliary sections of the transmission.

DISASSEMBLY

1. Remove the snap ring from the inside of the auxiliary drive gear.
2. Remove the spacer from the bore of the auxiliary drive gear.
3. Remove the rear mainshaft coupling snap ring.
4. Cut the lock wire and remove the bolts that attach the bearing retainer ring to the case. Insert three puller screws in the tapped holes of the retainer ring and tighten the bolts evenly and alternately to pull the assembly from the case (Fig. 7).
5. Remove snap ring from shoulder of auxiliary drive gear. Then, press or **drive the bearing retainer ring and the bearing from the gear.**
6. Move the mainshaft reverse gear to the rear as far as possible and remove the reverse gear snap ring. Then, move the reverse gear forward and against the low-speed gear and into engagement with the sliding clutch gear. Remove the snap ring and the reverse gear splined spacer from the mainshaft.
7. Working from inside the case, remove the left reverse idler shaft nut and washer.
8. Remove the plug (Fig. 8) from the reverse idler shaft bore. Using an impact puller, remove the reverse idler gear shaft. Remove the thrust washer, gear, and cup.
9. If necessary, remove the bearing inner race from the reverse idler shaft, and the bearing from the bore of the reverse idler gear (Fig. 8). If necessary, remove the bearing from the bore in case.
10. Move the mainshaft assembly to the rear as far as possible to separate the mainshaft gears from the countershaft gears. Tilt the front of the mainshaft and lift it from the case.
11. Cut the lock wire and remove the bolts that attach the bearing retainer to the front of the countershaft (Fig. 9). Remove the snap ring from the rear of the countershaft.
12. Using a mallet and a soft drift, drive the countershaft to the rear as far as it will go. This will partially unseat the front bearing from the shaft and the rear bearing from the case bore.
13. Using a suitable puller, remove the countershaft rear bearing from the shaft and case bore.
14. Move the countershaft forward until the front bearing is clear of the case. Then, pull the front bearing from the shaft.
15. Remove the left countershaft bearings in the same manner.
16. Remove the input shaft bearing retainer attaching bolts.
17. Working from inside the case tap the input shaft forward and remove the bearing retainer. Remove the snap ring from the input shaft bearing.
18. Move the input shaft assembly to the rear and remove it from the case.
19. Move the front of the right countershaft toward the center of the case and, at the same time, lift it from the case.
20. Remove the left countershaft in the same manner.
21. Working from inside the case, remove the right reverse idler shaft nut and washer.
22. Remove the plug (Fig. 8) from the reverse idler shaft bore. Using an impact puller, remove the reverse idler gear shaft. Remove the thrust washer and gear.
23. If necessary, remove the inner bearing race from the reverse idler shaft, and the bearing from the base of the reverse idler gear (Fig. 8). If necessary, remove bearing from case bore.

ASSEMBLY

1. Install the plug in the right reverse idler shaft.
2. Install the needle bearings in the bore of the reverse idler gear if they were removed.
3. Install the bearing inner race on the reverse idler shaft if it was previously removed.
4. Insert the threaded end of the idler shaft through the right wall of the case. As the shaft is moved forward, install the reverse idler gear and thrust washer. **Be sure the needle bearings in the gear are seated evenly on the shaft inner race before moving the shaft forward. The thrust washer should be positioned between the gear and the boss, with the slot toward the gear (Fig. 10).**
5. Position the washer over the threaded end of the shaft, and secure it with the elastic stop nut.
6. To install and time the countershaft assemblies, mark the drive gear tooth that aligns with the keyway of each countershaft. This tooth will be stamped with an O.
7. Position the left and right countershaft assemblies into the case. **Make sure the left countershaft assembly has the larger 47-tooth PTO gear.**
8. Mark any two adjacent gear teeth on the input shaft drive gear. Then, mark two adjacent teeth which are directly opposite the first set marked.
9. Install the input shaft through the front bore from inside the case. Move the shaft as far forward as possible and install the snap ring on the input shaft bearing.
10. Using a wood block, center the front of the left countershaft in the case bore. Then, mesh the marked tooth on the left countershaft drive gear with the two teeth marked on the input shaft main drive gear (Fig. 11).
11. With the countershaft as far to the rear as possible, install the rear bearing on the shaft and into the case bore.
12. Remove the wood block and install

the front bearing on the countershaft into the case bore.
13. Install the snap ring on the rear of the countershaft.
14. Position the bearing retainer plate on the front of the countershaft and secure with the attaching bolts and lock wire.
15. After installing the left countershaft assembly in the case, install the right countershaft in the same manner.
16. Position the input shaft bearing retainer to the case and secure with the attaching bolts.
17. Lower the mainshaft assembly into the case. Place a bar across the top of the case and install a support wire under the forward sliding clutch gear (Fig. 12).
18. Align the mainshaft assembly, making sure that the mainshaft gears and the corresponding gears on the countershafts are properly engaged, and that the quill bearing is seated in the pocket of the main drive gear (Fig. 12). Remove the support wire and bar. **Keep the mainshaft assembly in the forward position during the installation of the left reverse idler gear so that the gears will not slip out of mesh.**
19. Install the plug in the left reverse idler shaft.
20. Install the needle bearings in the bore of the reverse idler gear if they were removed.
21. Install the bearing inner race on the reverse idler shaft if it was previously removed.
22. Insert the threaded end of the idler shaft through the left wall of the case. As the shaft is moved forward, install the reverse idler gear and thrust washer. **Be sure the needle bearings in the gear are seated evenly on the shaft inner race before moving the shaft forward. The thrust washer should be positioned between the gear and the boss, with the slot toward the gear.**
23. Install the washer over the threaded end of the shaft, and secure it with the elastic stop nut.
24. Move the mainshaft reverse gear to the rear so that it engages the reverse idler gears. Then, install the reverse gear spacer (flat side inward) into the hub of the reverse gear. Install the reverse gear snap ring.
25. If the auxiliary drive gear was disassembled, place the bearing retainer on the gear and press the bearing into place. Install snap ring.
26. Position the auxiliary drive gear assembly into the rear case bore, align gap in auxiliary drive gear with key in mainshaft, and install the attaching bolts. Wire the bolts in groups of three.
27. Pull the mainshaft as far to the rear as possible and install the mainshaft rear snap ring.
28. Place the spacer in the bore of the auxiliary drive gear, and install the snap ring.
29. Install the auxiliary countershaft front bearings into the reverse idler shaft bores.

MAIN TRANSMISSION SUB-ASSEMBLIES

MAINSHAFT

Disassembly

1. Remove the fourth-fifth-speed sliding clutch gear from the mainshaft.
2. Remove the mainshaft reverse speed gear.
3. Remove the long key located between the splines of the mainshaft.
4. Remove the reverse gear washer and remove the first-reverse sliding clutch gear. Remove the remaining washers, spacers, and gears from the shaft. **When removing washers, spacers, and gears, note their location to facilitate the reassembly of the mainshaft. Keep washers and spacers with the gear from which they were removed; there is one spacer and one washer from each gear.**
5. If the quill bearing is to be removed, remove the snap ring and pull the bearing from the quill.
6. If necessary, remove the snap rings from each mainshaft gear.

Assembly

1. Except for the reverse gear, install a snap ring in each mainshaft gear if it was removed (Fig. 13).
2. Position the mainshaft in a vise, with the front end up.
3. Install the reverse gear washer (flat side down) in the fifth groove from the top of the mainshaft.
4. From the bottom, install the long key in the keyway of the mainshaft so that the forward end is moved through the slot of the reverse gear washer. Keep the snap ring groove in the key to the rear and to the outside. **Move the key upward to engage each washer as it is placed on the mainshaft.**
5. Install the first-reverse-speed sliding clutch gear on the mainshaft, making sure that the keyway is lined up with the key in the shaft.
6. Install the first-speed gear washer (flat side up) in the fourth groove from the top of the mainshaft. Then, move the key upward through the slot in the first-speed gear washer until the front of the key is level with the third groove from the top.
7. With the flat side down, install the first-speed gear spacer on the mainshaft and against the washer.
8. Install the first-speed gear (Fig. 13) on the mainshaft with the snap ring up. Engage the splines of the gear with the splines of the spacer.
9. With the snap ring down, install the second-speed gear on the mainshaft and against the first-speed gear.
10. Install the second-speed gear spacer and washer on the mainshaft, with the flat sides down. Move the key upward through the slot in the second-speed gear washer until it reaches the second groove from the top of the mainshaft.
11. Align the keyway in the second-third-speed sliding clutch with the key, and position the clutch on the mainshaft.
12. Install the third-speed gear washer (flat side up) in the second groove from the top of the mainshaft. Then, move the key upward to engage the washer.
13. Install the third-speed spacer with the flat side against the washer.
14. Install the third-speed gear (snap ring up) on the shaft and onto the splines of the spacer.
15. With the snap ring down, install the fourth-speed gear (Fig. 13) on the mainshaft and against the third-speed gear.
16. With the flat side up, install the fourth-speed gear spacer into the fourth-speed gear hub.
17. Install the fourth-speed gear washer (flat side down) on the mainshaft, and move the key upward to engage the washer.
18. Install the fourth-fifth speed sliding clutch gear, aligning the large slot in the clutch gear with the keyway in the shaft.
19. Remove the mainshaft assembly from the vise and align the snap ring groove in the key with the second from the end snap ring groove in the mainshaft.
20. Install the reverse gear on the mainshaft and move it as far forward as possible into engagement with the sliding clutch gear. **Do not install the reverse gear spacer and snap ring until the mainshaft assembly is installed in the transmission.**
21. Install the front mainshaft snap ring

on the mainshaft and key, securing the key to the mainshaft.

INPUT SHAFT

Disassembly

1. Mount the shaft in a soft-jawed vise. Relieve the peening on the bearing nut, and remove the nut. **It has a left thread.**
2. Using the rear face of the input shaft gear as a base, mount the assembly in a press, and press the shaft through the gear. This will free the bearings, spacer, and gear from the shaft.

Assembly

1. Install the snap ring in the drive gear if it was removed (Fig. 14).
2. Install the drive gear on the shaft with the snap ring toward the front.
3. Install the drive gear spacer.
4. Press the drive gear bearing on the shaft, with the snap ring toward the front.
5. Install the bearing attaching nut, and torque to specifications. This nut has a left-hand thread. Peen the nut at the slots milled into the shaft.

COUNTERSHAFT

Disassembly

Both countershafts are identical, except for the number of teeth on the PTO gears; thus, they are disassembled in the same manner.

1. Remove the snap ring from the rear of the countershaft.
2. Using the rear face of the reverse gear as a base, press the gear from the countershaft (Fig. 15).
3. Using the second-speed gear as a base, press the first and second-speed gears from the countershaft (Fig. 16).
4. Using the fifth-speed gear as a base, press the countershaft out of the third, fourth, PTO, and fifth-speed gears (Fig. 17).
5. Remove the three keys and spacer from the countershaft.

Assembly

Except for the number of teeth on the PTO gears, the countershafts are identical and assembled in the same manner.

1. Install the front washer over the rear of the countershaft and position the keys in the keyways (Fig. 18).
2. Press the countershaft gears on the shaft **one at a time; the drive, PTO, third and first-speed gears are installed with the long hubs to the rear. The fourth, second, and reverse-speed gears are installed with the long hubs to the front (Fig. 18). The left countershaft is equipped with a 47 tooth PTO gear; the right side is equipped with a 45 tooth gear. After installing the PTO gear on the countershaft, mark the assembly either left or right to correspond with the installed PTO gear.**
3. Install the snap ring on the rear of the countershaft.

GEAR SHIFT HOUSING

Disassembly

1. Tilt the housing and remove the tension springs and balls from the bores in the top of the housing.
2. Set the housing in a vise with the plunger side up.
3. Cut the lock wires, and remove the lock screws from each shifter shaft prior to its removal.
4. Move the top and center shifter shafts to the rear and out of the housing. Remove the shifting fork and block from each shaft. As the neutral detent in the center shaft clears the housing boss, remove the interlock pin (Fig. 19).
5. Remove the actuating plunger from the bore in the housing (Fig. 19).
6. Move the lower shifter shaft to the rear and out of the housing. Remove the shifting fork from the shaft. **Do not lose the interlock balls as the lower shaft is removed.**

Assembly

Install the shifter shaft through the rear bores of the housing with the neutral and detent notches to the rear. Keep the shafts in the neutral position when installed.

1. Place the housing in a vise with the plunger side up.
2. Install the first and reverse-speed shifter shaft in the bottom bore and through the shifting fork. Install the set screw and secure with lock wire.
3. Install the actuating plunger in the front opening of the housing, and a three-quarter inch interlock ball in the rear opening (Fig. 20).
4. Position the second and third-speed shifter shaft in the center bore and through the shift block and fork. **Be sure to install the interlock pin in the bore at the neutral notch. Install the set screws and secure with lock wire. Keep the shifter shaft so that the interlock pin remains in a vertical position during the remainder of the assembly. Rotating the shaft will cause the interlock pin to jam into the tension spring bores.**
5. Install a three-quarter inch ball in the rear opening of the housing.
6. Position the fourth and fifth-speed shifter shaft in the upper bore and through the shifting block and fork. Install the set screws and secure with lock wire (Fig. 21).
7. Remove the gear shift housing from the vise and place it on a work bench. Install the three detent balls and springs into the top of the housing.

AUXILIARY TRANSMISSION

SEPARATION OF MAIN AND AUXILIARY SECTIONS

1. Disconnect the air hoses at the air valve.
2. Remove the air filter and air regulator valve assemblies.
3. Remove the four bolts securing the air valve to the adapter plate and remove the valve.
4. Remove the alignment sleeve, spring, and actuating pin from the air valve adapter plate. Then, remove the plate from the transmission.
5. With the transmission in neutral, remove the gear shift housing cover.
6. Lock the transmission in two gears and remove the U-joint flange.
7. Remove the bolts that attach the auxiliary section to the transmission case. Install three puller screws in he tapped holes of the rear plate and tighten them alternately and evenly to move the auxiliary section to the rear just far enough to break the gasket seal.
8. Attach a chain hoist to the auxiliary section and continue to move it to the rear until free of the transmission (Fig. 22).
9. Remove the bolts and nuts that attach the clutch housing to the transmission and remove the housing.

JOINING OF MAIN AND AUXILIARY SECTIONS

1. Position the clutch housing to the transmission case, and install the attaching bolts and nuts. Torque the bolts and nuts to specifications.
2. Using a chain hoist, position the auxiliary section to the transmission. It may be necessary to rotate the drive gear to properly mesh the gears. Install the attaching bolts and tighten them securely.
3. With the transmission locked in two gears, install the speedometer drive gear and U-joint flange on the mainshaft. Torque the nut to specifications. **If the speedometer drive gear is not used, be sure to install a replacement spacer of the same width.**
4. Position the gear shaft housing cover

to the transmission and install the attaching bolts.
5. Install the air valve plate and housing.
6. Install the air filter and air regulator valve assemblies, and connect the air hoses at the air valve.

DISASSEMBLY OF AUXILIARY SECTION

1. Remove the shift cylinder cover bolts and remove the cover.
2. Remove the nut from the end of the shifter shaft. Using puller screws, remove the piston from the shift cylinder.
3. Remove the bolts that attach the shift cylinder housing to the rear plate.
4. Cut the lock wires and remove the set screws from the shifting fork. If necessary, rotate the shift cylinder housing to expose the set screws (Fig. 23).
5. Push the shifter shaft to the inside, through the fork hub, and out of the cylinder housing. Remove the shifting fork and shift cylinder housing from the plate.
6. If necessary, remove the O-rings from the piston and shift cylinder housing.
7. To remove the countershaft assemblies, place the rear plate on wood blocks so that the front of the countershafts are approximately two inches from the work bench. Also, **place blocking under the synchronizer assembly to prevent it from moving. If the synchronizer moves downward and off the mainshaft, the springs will be forcibly ejected from the synchronizer.**
8. Remove the bolts that attach the countershaft rear bearing covers to the plate. Remove the covers.
9. Cut the lock wires and remove the rear bearing retainer plate bolts. Remove the plate from each countershaft.
10. Using a hammer and a soft drift, tap the rear of the countershafts to unseat them from the bearings.
11. Remove the countershaft bearings by tapping lightly on the outer race with a soft mallet.
12. Pull the synchronizer assembly from the output shaft as a complete unit.
13. Reposition the rear plate on the wood blocks so that the threaded end of the output shaft is pointed upward.
14. Using a hammer and a soft drift, drive the output shaft through the rear bearing.
15. Remove the bolts that attach the rear bearing cover to the rear plate. Remove the cover. Remove the oil seal from the cover if it appears to be damaged.
16. Remove the bearing, two bearing cups, and the outer spacer from the plate bore.

ASSEMBLY OF AUXILIARY SECTION

1. With the rear plate on a work bench, place the front cup (taper to the inside) of the rear bearing into the rear bore of the plate.
2. Place the bearing outer spacer on the front cup.
3. Place the rear cup on the spacer and tap the two cups and spacer into the rear plate bore.
4. Place the rear plate over the output shaft. Be sure that the bearing on the shaft is seated on the rear plate front bearing cup.
5. Install the rear bearing on the output shaft.
6. Install a new oil seal in the rear bearing cover if it was removed. Position the cover to the rear plate and install the attaching bolts, using a star washer at the hole which intersects with the speedometer bore.
7. Install the synchronizer assembly on the output shaft, with the low-speed synchronizer ring toward the low-speed gear.
8. To install and time the auxiliary countershafts, mark the gear tooth which is stamped O on the small diameter low range gear of each countershaft. This tooth will be aligned with the keyway in the countershaft drive gear. These two teeth one on each countershaft, must both mesh at the same time with the output shaft low-speed gear and be in directly opposite positions.
9. Mark any two adjacent teeth on the output shaft low-speed gear. Then, mark the two adjacent teeth, which are directly opposite the first set marked. There should be the same number of teeth between the markings on each side of the gear.
10. Place the rear plate assembly on blocking, with the threaded end of the output shaft up. Make sure blocking is also placed under the synchronizer assembly to prevent it from dropping from the output shaft.
11. Place each countershaft into position and place blocking under each shaft. For correct timing, be sure to place the marked teeth of the countershafts into mesh with the marked teeth of the low-speed gear.
12. Install the rear bearing on each countershaft. Recheck the gears to be sure that they are correctly timed.
13. Position a rear bearing retainer plate on each countershaft and secure them with the attaching bolts and lock wire. Install the rear bearing covers.
14. Install a new O-ring in the shift cylinder bore if it was removed.
15. Position the shifting fork on the sliding clutch gear, and install the shift cylinder into the bore of the rear plate.
16. Insert the threaded end of the shifter shaft through the front of the shift cylinder, through the shifting fork hub, and into the cylinder bore. Install the set screws and secure them with lock wire.
17. Install new O-rings on the shift cylinder piston if they were removed.
18. Position the piston in the shift cylinder bore and secure with the elastic stop nut. Torque the nut to specifications.
19. Position the cover on the shift cylinder (air port to the upper left) and secure with the attaching bolts.

AUXILIARY SECTION SUB-ASSEMBLIES

COUNTERSHAFT

Disassembly

1. To remove the countershaft gear, remove the snap ring and press the gear from each shaft (Fig. 24). (Some units may have the drive gear welded to countershaft and cannot be disassembled).
2. Remove the key from each countershaft.

Assembly

1. Install a Woodruff key on each countershaft and press the countershaft onto each drive gear.
2. Install the snap ring on the front of each countershaft.

SYNCHRONIZER

Disassembly

1. Place the synchronizer assembly on a work bench. Remove the direct (high range) cone synchronizer ring from the pins of the low-speed synchronizer ring. **Place a cloth over the ring during removal to catch the three springs installed in the bores of the direct cone synchronizer.**
2. Remove the sliding clutch gear from

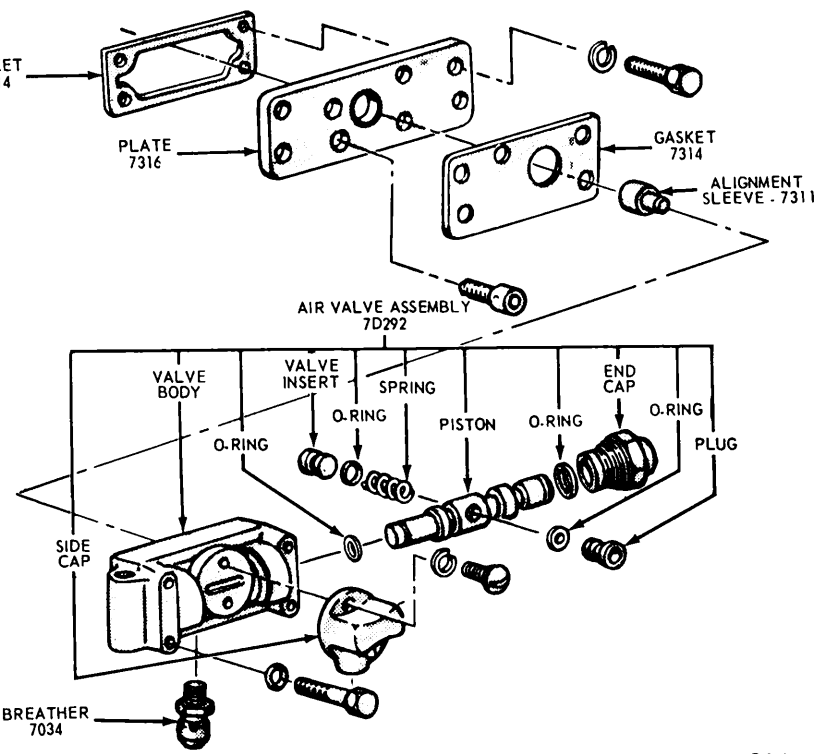

FIG. 5 Air Valve Disassembled

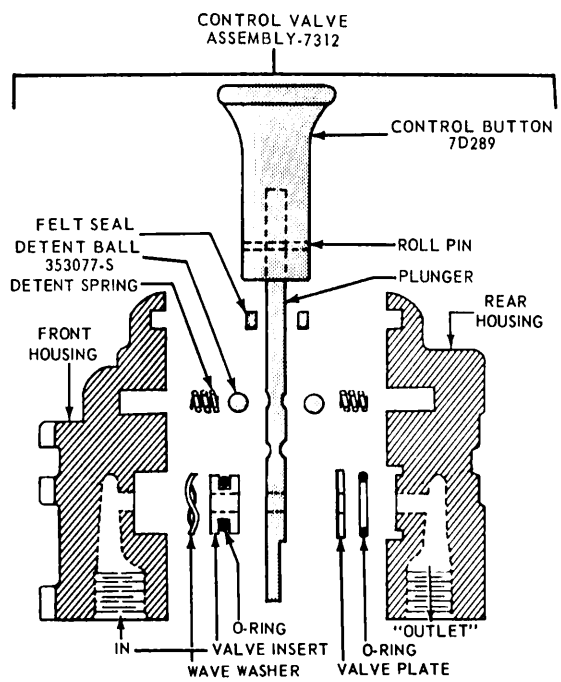

FIG. 6 Master Control Valve Disassembled

the pins of the low-speed synchronizer.

Assembly

1. Place the low-speed synchronizer ring on a work bench with the pins up. Then, install the clutch sliding gear on the pins.
2. Install the three springs into the bores of the direct synchronizer ring (Fig. 25) and place the direct synchronizer over the pins of the low-speed synchronizer ring.
3. Apply pressure to the direct synchronizer ring to compress the springs and fully seat the direct synchronizer on the pins of the low-speed synchronizer.

OUTPUT SHAFT

Disassembly

1. Remove the inner bearing spacer from the output shaft (Fig. 26).
2. Using the front face of the low-speed gear as a base, press the shaft through the gear, washers, and bearing.
3. Remove the splined and stepped washers from the shaft.

Assembly

1. Set the output shaft on a work bench with the threaded end up. Install the stepped and splined washers on the shaft (Fig. 26). Be sure the small diameters are toward the threaded end of the shaft.
2. Install the low-speed gear on the shaft, with the flat side up. hen, install the cone-shaped washer, with the flat side against the gear.
3. Install the bearing on the shaft, with the taper toward the threaded end.
4. Install the inner bearing spacer on the shaft and against the bearing.

DESCRIPTION

TRANSMISSION

The RTO and RTOF-9513 series transmissions are designed for medium to heavy duty vehicles, for both on-highway or off-highway use.

The twin countershaft design, which splits torque evenly between the two countershafts, provides a high torque capacity to weight ratio. Because of torque splitting, each gear set carries only half of the load, greatly reducing the face width of each gear.

Another unique design feature is the floating gear principle. The mainshaft gears when not engaged float between the countershaft gears, eliminating the need for gear sleeves and bushings. All gears are constant mesh and have spur type teeth.

These transmissions have 13 progressive forward ratios and two reverse, consisting of a five-speed front section, a sychronized two-speed range section and an over-drive splitter gear (Fig. 1). One ratio in the front section is used only in low range as a low-low or starting gear. The remaining four ratios in the front section are used once through the reduction (low) gear in the range section and once through direct (high) in the range section.

While in high range, the four ratios can be split by the over-drive splitter to give eight speeds in high range. All 13 ratios are progressively spaced. Ratios are never split while the transmission is in low range.

The shifts between low and high range are made automatically by air upon pre-selection by the driver. The splitter gear is engaged by air when selected by the driver.

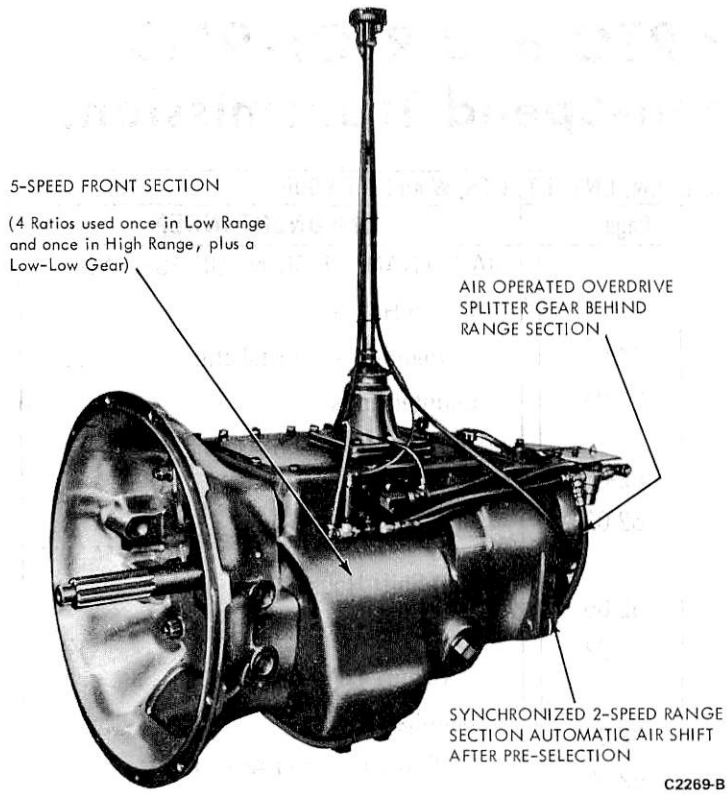

FIG. 1 RTO-9513 Transmission

REMOVAL AND INSTALLATION

GEAR SHIFT LEVER HOUSING

Removal

Turn out the four capscrews and lift the gear shift lever housing or remote control housing from the shifting bar housing.

Installation

1. Make sure the shifting notches on bars in housing are aligned in the neutral position.
2. Install the gear shift lever housing on shifting bar housing, fitting lower end of lever into notches in shifting blocks and yoke.
3. Install the attaching capscrews, tighten evenly and securely.

AIR SHIFT CONTROLS

AIR VALVE

Removal

1. Remove the floor mat and the floor plate.
2. Place the gear shift lever in the neutral position. Drain the air from the system.
3. Disconnect and remove air lines from the range shift air cylinder at rear of transmission.
4. If necessary, remove fittings from range shift cylinder.
5. Turn out the four capscrews and remove the air valve from adapter plate (Fig. 2).
6. Remove the alignment sleeve from air valve or from bore in adapter plate.
7. Remove the spring and actuating pin from bore in adapter plate.
8. Turn out the two capscrews and the two Allen head screws and remove the adapter plate from transmission.
9. If necessary, remove fittings from air valve.

Installation

1. Place the gear shift lever in the neutral position. The lever must remain in this position until air pressure has been admitted to the system.
2. Apply air pressure to the front port of the air valve to move the pistons to the rear. **Failure to perform these two steps may result in damage to the valve.**
3. Install the adapter plate on transmission to align large bore in plate with bore in transmission. Secure with two capscrews in bores at rear of plate and with two nylon Allen head screws in counterbored holes. Use loctite on nylon screws.

Use the small alignment sleeve to check plate bore alignment with case bore. If not properly aligned, loosen capscrews and Allen head screws and reposition adapter plate.

4. Install the actuating pin in bore in adapter plate and install the spring on actuating pin.
5. **Before installing alignment sleeve, check bore in which it is to be installed to make sure the stop piston in air valve is either in a forward or rear position.** Install the alignment sleeve in bore in air valve.
6. Install the air valve on adapter plate, tighten capscrews evenly and securely.
7. Install fittings in shift cylinder if previously removed.

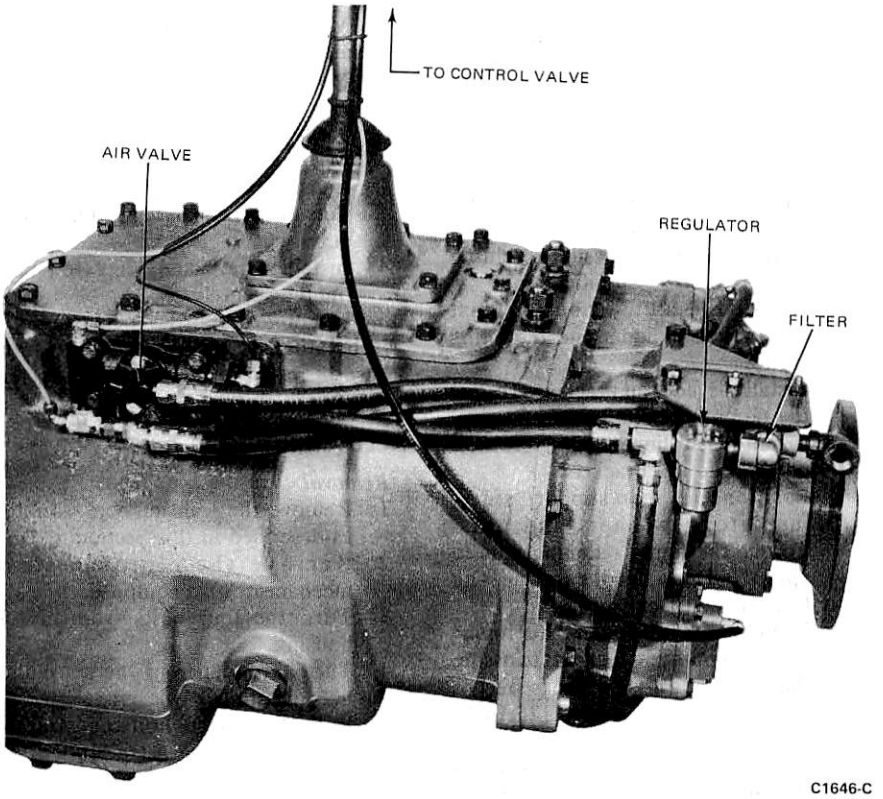

FIG. 2 Transmission Air System

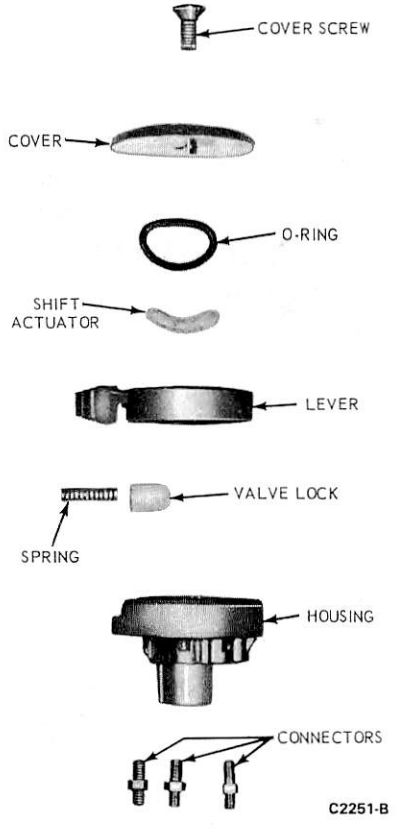

FIG. 3 Range and Splitter Control Disassembled

RANGE AND SPLITTER CONTROL VALVE

Removal

1. Disconnect the three control air lines; at valve cover in rear of transmission and at air valve on side of transmission (Fig. 2).
2. Disconnect air lines from control valve on gear shift lever (Fig. 3).
3. Loosen jam nut and turn the control valve from lever. Remove jam nut.
4. Remove the control valve air lines and sheathing from lever.

Installation

1. Install 1/4 inch ID air line between tee in regulator and side air port in the splitter shift cylinder cover. This is the constant air supply for operation of the splitter shift cylinder.
2. Install O-ring on gear shift lever. Install the splitter control jam nut on threads of gear shift lever.
3. Install three fittings, 1/16 inch pipe thread, in splitter control. Install in **S** port which is the supply port, and in the **F** port which is the signal line to the air port, and in the **R** port which is the signal line to the splitter cylinder.
4. Install the splitter control on threads of gear shift lever and secure with jam nut. Install with trademark toward the front.
5. Install black 1/8 inch OD, .078 inch ID nylon air line in **F** port of control valve. Install white 1/8 inch OD, .078 inch ID nylon air line in **S** port of control valve. Install black line in **R** port.
6. Measure air lines for proper length. Measure sheathing for proper length: approximately 44 inches. Cut small hole in side of sheathing approximately 24 inches from end which is to be used as upper or top portion.
7. Thread white line and one black line through top portion of sheathing and out small hole cut in sheathing; thread one black line through entire length of sheathing.
8. Thread air lines and sheathing through O-rings on gear shift lever.
9. Connect the black line from **R** port to the 90 degree ell in rear air port in the splitter shift cylinder cover at rear of transmission.
10. Connect the black air line from **F** port to the pilot end of air valve.
11. Connect the white nylon line to supply port of air valve.

AIR REGULATOR AND FILTER

Removal

1. Disconnect and remove air line between the air regulator and splitter cylinder cover.
2. Disconnect and remove the air lines from air valve on side of transmission.
3. Turn out the two capscrews which attach the filter bracket to transmission and remove the filter, regulator and air line from transmission (Fig. 4).

Installation

1. Install nipple in output port of air filter.
2. Install air regulator on nipple.
3. Install regulator and filter on mounting bracket with clamp.
4. Install nipple and tee in regulator.
5. Install the air filter and regulator bracket on auxiliary housing.
6. Install 1/4 inch ID air line between bottom port of tee in air regulator and supply port in splitter cylinder.
7. Install 1/4 inch air line between regulator and air valve supply port. Install 1/4 inch air line between rear port in side cap of air valve and range shift cylinder cover. Install 1/4 inch air line between air valve and range cylinder.

TRANSMISSION ASSEMBLY

Removal

1. Bleed the air reservoirs. Disconnect the air line at the top right side of the transmission.

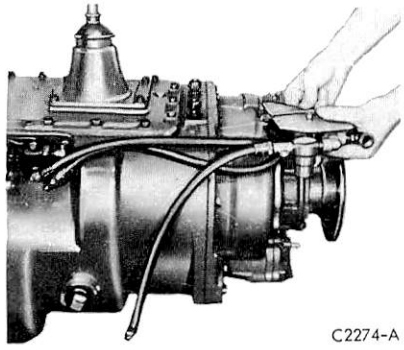

FIG. 4 Removing Air Regulator and Filter

2. Disconnect the drive shaft at the parking brake drum and disconnect the speedometer cable.
3. After cleaning the area around the cross-shaft housing, remove the housing and tie it out of the way. Cover the opening in the gear shift housing.
4. Remove the shift control cable retaining clamp and disconnect the cable at the air shift valve. Remove the two clevis pins securing the air shift cylinder (necessary for clearance of the transmission jack).
5. Disconnect the clutch release lever retracting spring. Remove the slave cylinder mounting bolts and position the slave cylinder out of the way.
6. Remove all but two of the clutch housing attaching bolts at the engine.
7. After securing a transmission jack to the transmission, raise the transmission slightly to relieve pressure at the side rail mounting brackets.
8. Disconnect the parking brake rod clevis and both air line clamps (on the side rail brackets).
9. Remove the side rail bracket stud nuts, insulators and reinforcements; then remove each bracket.
10. After removing the remaining clutch housing retaining bolts, pull the transmission rearward to clear the input shaft.
11. Raise the front of the vehicle enough to provide clearance in removing the transmission. Install safety stands and remove the transmission from the vehicle.

Installation

1. Install two pilot studs in the clutch housing and remove the clutch housing dust cover.
2. Position the transmission under the truck. Lower the truck.
3. Position the input shaft in the clutch discs and start two of the transmission retaining bolts.
4. Torque all transmission-to-clutch housing bolts to specification.
5. Install the clutch housing dust cover, slave cylinder and retracting spring.
6. Install the side rail brackets. Torque the mounting bolts to specification. Install the air line retaining brackets on the side rail brackets.
7. Position the rear support studs, insulators, washers and nuts. Torque the upper retaining nuts to specification and remove the transmission jack.
8. If necessary, loosen the lower retaining nuts and lock nut to assure that the transmission hangs freely.
9. Insert a feeler gauge (0.125 inch) between the lower retaining nut and its washer. **Do not apply pressure to the engine or the stud shoulder. Turn the nut downward until there is slight pressure on the gauge.**
10. Repeat steps 8 and 9 for the other side.
11. Torque the lock nuts to specification.
12. Install the air shift cylinder, connect the air shift cable and install the cable clamp.
13. Install the cross-shaft housing and torque the mounting bolts to specification.
14. Connect the speedometer cable, the brake rod and the air line.
15. Start the engine to build up air pressure, connect the drive shaft and check for air leaks.

SUB-ASSEMBLIES

SHIFTING BAR HOUSING

Removal

With gear shift lever housing removed, turn out the attaching capscrews, jar to break gasket seal and lift the shifting bar housing from transmission.

Installation

1. Make sure the shifting bar housing assembly is in the neutral position.
2. Make sure the sliding clutch gears on the mainshaft are in the neutral position.
3. Install the shifting bar housing on transmission, fitting yokes into yoke slots of corresponding sliding clutch gears.
4. Install the attaching capscrews and tighten securely.
5. Install gear shift lever housing.

If breather is not used at left front bore in top of housing, make sure this opening is plugged.

CLUTCH HOUSING

Removal

1. Remove the transmission assembly as described in this Section.
2. Remove the clutch release mechanism if so equipped.
3. Turn the four bolts from clutch housing.
4. Turn the nuts from the six clutch housing studs.
5. Pull the clutch housing straight forward and off case. It will be necessary to break gasket seal by jarring housing lightly with soft hammer. The clutch housing is piloted on the drive gear bearing cover.

Installation

1. Install the front bearing cover, tighten capscrews securely.
2. Install the clutch housing on the six studs on front of case. Move evenly against case as drive gear bearing cover pilots the clutch housing on case.
3. Install lock washers and nuts on studs and install the four bolts in housing.
4. Secure the nuts on studs with 180 to 190 ft-lbs of torque.
5. Secure the bolts with 90-100 ft-lbs of torque.
6. Install the clutch release mechanism if so equipped.
7. Install the transmission assembly in the vehicle.

DISASSEMBLY AND ASSEMBLY

GEAR SHIFT LEVER HOUSING

Disassembly

1. Remove the rubber dust protector from gear shift lever.
2. Mount the assembly in a vise with the large opening up.
3. Free the gear shift lever tension spring by twisting a heavy screwdriver between the spring and housing, forcing the spring from its seat under lugs case in housing.
4. Remove the tension spring from housing.
5. Withdraw the tension spring washer and gear shift lever out through bottom of housing.
6. Remove the nut and lock washer from outer end of gear shift lever pivot pin (Fig. 5).
7. Remove pivot pin by forcing it inward and through wall of housing.

Assembly

1. Install the pivot pin in bore in housing, thread end outward.
2. Install the lock washer and nut on pivot pin.
3. Mount the housing in a soft-jawed vise with the large, bottom opening upwards.
4. Insert the gear shift lever in housing, fitting slot in pivot ball of shift lever on pivot pin.
5. Install the tension spring washer in housing.
6. Install the tension spring in housing, seating spring under lugs cast inside the housing.
7. Remove from vise and install the rubber dust protector over the gear shift lever and against neck of housing.

AIR SHIFT CONTROLS

AIR VALVE

Disassembly

1. Remove all air line fittings and the vent from the valve.
2. Remove the two screws securing the side cap to the valve body and remove the cap (Fig. 6).
3. Remove the valve insert and spring from the piston. Remove the O-ring from the valve insert.
4. Remove the end cap and piston from the valve body. Remove the two O-rings from the piston.
5. Remove the nylon plug from the piston and remove the O-ring from the plug.

Assembly

1. Use all new O-rings and lubricate them with a thin film of vaseline before installing them.
2. Install O-rings on the piston and nylon plug. Install the plug in the piston (Fig. 6).
3. Insert the piston in the valve body and install the end cap. Tighten the cap securely.
4. Install the spring into the piston.
5. Install an O-ring on the valve insert and install it in the piston.
6. Secure the side cap to the valve body with the attaching screws and lock washers. Tighten the screws securely.
7. Coat the fittings with sealer and install them in their respective ports. Install the vent in the body.

RANGE AND SPLITTER CONTROL VALVE

Disassembly

The control valve is easily disassembled by removing the top plate screw (Fig. 3).

Assembly

Reassemble the splitter control valve as shown in Figure 3. Critical assembly factors are:

1. Make sure jam nut locking control valve to the gear shift lever is secure.
2. Make sure that top plate screw is torqued with 90 to 120 in-lbs. A loose top plate screw can affect valve operation.
3. When assembling, lubricate O-ring and O-ring carrier with a barium base grease.

MAIN TRANSMISSION

Refer to Auxiliary Transmission Section for instructions on separating the main and auxiliary sections of the transmission.

Disassembly

1. Remove the mainshaft rear coupling snap ring from groove in mainshaft, located inside bore of drive gear.
2. Cut lock wire and remove the six capscrews which attach the bearing retainer ring to case.
3. Insert three puller screws in tapped holes in retainer ring and tighten evenly to pull assembly from case bore (Fig. 7).
4. Secure gear in vise and remove snap ring from auxiliary drive gear.
5. Press, or use driver, to remove the bearing retainer ring and bearing from the auxiliary drive gear.

To remove the left reverse idler gear, the reverse gear on the mainshaft must be moved forward to provide the necessary clearance; this procedure is included in the following instructions.

6. Move the mainshaft reverse gear to the rear as far as possible and remove the snap ring from ID of gear.
7. Move the mainshaft reverse gear forward and against the low-speed gear and into engagement with the sliding clutch gear.
8. Remove auxiliary countershaft front bearing from reverse idler bore.
9. Inside the case, turn the elastic stop nut from threads of the reverse idler shaft and remove the washer.
10. Remove the plug from bore of reverse shaft.
11. Insert impact puller (1/2-13 thread) and remove the reverse idler shaft. This will unseat the countershaft front bearing of the auxiliary section from case bore.
12. As the reverse idler shaft is moved to the rear, remove the thrust washer and gear from shaft and case.
13. If necessary, remove the bearing inner race which is a slip fit from the reverse idler shaft.
14. If necessary, press bearing from bore of reverse idler gear.
15. Remove cup from bore.

In order to remove the mainshaft assembly, it will be necessary to remove bearings from right countershaft. This procedure is included in the following instructions.

16. Remove the bearing retaining snap ring from groove at rear of the right countershaft.
17. Using blunt punch with care from inside of case, move the countershaft rear bearing to the rear and from shaft.
18. Cut lock wire, turn out the two capscrews and remove the bearing retainer plate from front of right countershaft.
19. Move the right countershaft to the rear approximately 1/2 inch, using soft bar and maul against front of countershaft.

Use soft bar with large, flat end to prevent damage to retainer plate capscrew holes in front of countershaft.

20. Move the countershaft assembly forward as far as possible to expose front bearing snap ring. Use puller or pry bars to remove front bearing.
21. Block the right countershaft toward case wall, as far forward as possible.

22. With the mainshaft reverse gear against the first-speed gear, pull the mainshaft to the rear and lift the assembly from case.
23. Remove snap ring from groove at rear of left countershaft.
24. Using blunt punch with care from inside of case, move the countershaft rear bearing to the rear and from shaft.
25. Cut lock wire, turn out the two capscrews and remove the bearing retainer plate from front of countershaft.
26. Move the countershaft to the rear approximately 1/2 inch, using soft bar and maul against front of countershaft. This will partially unseat front bearing from shaft. **Use soft bar with large, flat end to prevent damage to retainer plate capscrew holes in front of countershaft.**
27. Move the countershaft forward until front bearing snap ring is exposed.
28. Pull or pry the front bearing from shaft.
29. Turn out capscrews from the front bearing cover.
30. From inside the case move the drive gear forward, removing the cover as drive gear bearing is moved forward. Use soft bar and hammer to move drive gear (Fig. 8).
31. Remove the snap ring from the drive gear bearing.
32. Move the drive gear assembly to the rear and into inside of case and remove the case, working past the countershaft gears.
33. Move the front of the right countershaft towards center of case and upwards and remove from case.
34. Move the front of the left countershaft towards center of case and upwards and remove from case.
35. Repeat steps 6 through 12 to remove the right reverse idler assembly (Fig. 9).

Assembly

Before starting the reassembly, check to make sure all three magnetic discs are in place in bottom of case.

1. Install plug in threaded bore in end of reverse idler shaft.
2. Press the needle bearing in bore of the reverse idler gear if previously removed. Install cup on shaft.
3. Install the inner race of bearing on the reverse idler shaft if previously removed (Fig. 9).
4. Insert the thread end of shaft through the lower, right wall of case.
5. As shaft is moved forward, install the thrust washer and reverse idler gear on shaft, seating gear on inner race of bearing. Washer is positioned between gear and boss on inside of case.
6. Seat shaft securely in bore. **Make sure needle bearings are located on inner race of bearing before moving the shaft forward.**
7. Install washer over thread end of shaft.
8. Install elastic stop nut on shaft. Install auxiliary countershaft front bearings in reverse idler bores.
9. On the drive gear of each countershaft, mark the gear tooth which aligns with the keyway in shaft. This tooth will be stamped with an O (Fig. 10).
10. Place the left countershaft into position in case, but do not install bearings. **Make sure the left countershaft assembly has the larger 47-tooth PTO gear.**
11. Place the right countershaft into position in case, but do not install bearings. **Make sure the right countershaft assembly has the 45-tooth PTO gear. Countershafts will now be in approximate position but without bearings.**
12. Mark any two adjacent gear teeth on the drive gear. Then mark the two adjacent teeth which are directly opposite the first set marked. There should be the same number of teeth between the marking on each side of the gear.
13. Make sure snap ring is removed from the drive gear bearing.
14. Insert the drive gear shaft from inside the case through front bore and move as far forward as possible so as to expose snap ring groove in bearing. It will be necessary to work the drive gear past the PTO gears on countershafts.
15. Install snap ring in groove in drive gear bearing.
16. Use block to center rear of left countershaft in the case bore.
17. Mesh the marked tooth on left countershaft drive gear with two marked teeth on the main drive gear.
18. Start the front bearing in case bore. Center countershaft assembly and install front bearing on shaft and into case bore.
19. Remove block at rear of shaft and install the countershaft rear bearing on shaft and into case bore.
20. Install the bearing retainer plate on front of countershaft, tighten and wire the two capscrews securely.
21. Install the snap ring in groove at rear of countershaft.
22. Block the right countershaft assembly towards wall of case as far as possible to provide clearance for the installation of mainshaft.
23. With the reverse gear as far forward as possible on the mainshaft, lower rear of mainshaft into case and through rear bearing bore.
24. Lower front of mainshaft into position and move forward to seat in pocket of drive gear; at the same time meshing mainshaft gears with corresponding gears on left countershaft.
25. Move the right countershaft to mesh gears with corresponding gears on mainshaft, and at the same time mesh marked tooth on the countershaft drive gear with the two marked teeth on the main drive gear.
26. Use blocking to center rear of right countershaft in case bore and to center rear of mainshaft in rear bearing bore.
27. Start the front bearing in case bore. Center countershaft assembly and install the front bearing on shaft and into case bore.
28. Remove block at rear of countershaft and install the countershaft rear bearing on shaft and into case bore.
29. Install the bearing retainer plate on front of countershaft, tighten and wire the two capscrews securely.
30. Install snap ring in groove at rear of countershaft.
31. Repeat steps 1 through 8 to install the left reverse idler gear assembly.
32. Move the reverse gear as far as possible to the rear, against rear wall of case, and mesh teeth with those of the reverse idler gears.
33. Install snap ring in groove in ID of reverse gear.
34. Move reverse gear forward on shaft and into correct position.
35. Place the bearing retainer ring on auxiliary drive gear.
36. Press the bearing on drive gear, snap ring towards retainer.
37. Install snap ring in groove in shoulder of auxiliary drive gear.
38. Install the auxiliary drive gear assembly into rear case bore, fitting over rear of mainshaft and seating bearing in case bore. Align gap in ID of gear with key in mainshaft.
39. Install the six capscrews which attach the retainer ring to case. Wire capscrews in groups of three.
40. Pull the mainshaft as far to the rear as possible and install the rear mainshaft coupling snap ring in groove in mainshaft located inside bore of drive gear.

MAIN TRANSMISSION SUB-ASSEMBLIES

MAINSHAFT

Disassembly

1. Remove the third-fourth speed sliding clutch gear from mainshaft.

2. Remove the mainshaft front coupling snap ring from rear of mainshaft.
3. Pull the long key, located between splines of mainshaft, to the rear and from mainshaft.
4. Remove reverse gear spacer and washer.
5. Remove reverse gear and first-reverse sliding clutch.

When removing washers, spacers and gears, note their location to facilitate the reassembly of the mainshaft (Fig. 11). Keep washers and spacers with the gear from which they were removed; there is one spacer and one washer for each gear. The spacers have external splines and the washers have internal splines.

6. Work washers, spacers and gears from mainshaft. It will be necessary to turn washers, located under each gear, to align with splines of mainshaft.
7. If necessary, remove snap rings from groove in ID of each gear.

Assembly

1. Mount the mainshaft in a vise with the front end up. Keep keyway clear for the insertion of the long key.
2. Install snap ring in groove in ID of all mainshaft gears except the reverse gear.
3. Install the reverse gear washer on mainshaft in the fifth radial groove from the top. Turn square slot in ID of washer to align with keyway in shaft. Install with flat side down. **For reference purposes, the gear washers are internally splined and contain a square keyway. The gear spacers are externally splined to engage splines of gears. There is one washer and one spacer for each gear.**
4. From the bottom, install the long key in keyway in mainshaft so that forward end is moved through slot in the reverse gear washer. Keep snap ring groove in key to the rear and to the outside. **The key is to be moved upwards to engage each washer as it is placed on mainshaft.**
5. Install the low low-reverse speed sliding clutch gear on mainshaft, aligning large slot in ID of gear with key in shaft.
6. Install the low low-speed gear washer, flat side up, on mainshaft in the fourth radial groove from top. Turn square slot in ID of washer to align with keyway in shaft.
7. Move the key upwards through slot in low low-speed gear washer until front of key is level with the third radial groove from top.
8. Install the low low-speed gear spacer, flat side down, on mainshaft and against the washer.
9. Install the low low-speed gear, snap ring up, on mainshaft, engaging splines of gear with splines of spacer.
10. Install the first-speed gear, snap ring down, on mainshaft and against the low low-speed gear.
11. Install the first-speed gear spacer, flat side up, on mainshaft, engaging splines of gear with splines of spacer.
12. Install the first-speed gear washer, flat side down, on mainshaft and against the first-speed spacer.
13. Turn the first-speed gear washer until square slot in ID aligns with keyway of mainshaft.
14. Move key upwards to engage the first-speed gear washer and continue to move key until it reaches the second radial groove from top in mainshaft.
15. Install the first-second speed sliding clutch on mainshaft, aligning large slot in ID of clutch gear with key in shaft.
16. Install the second-speed gear washer on mainshaft and in second radial groove from top in mainshaft.
17. Turn washer until square slot in ID aligns with keyway of mainshaft and move key upward to engage washer. Install washer with flat side up.
18. Install the second-speed gear spacer on mainshaft, flat side against washer.
19. Install the second-speed gear, snap ring up, on mainshaft, engaging splines of gear with splines of spacer.
20. Install the third-speed gear, snap ring down, on mainshaft and against the second-speed gear.
21. Install the third-speed gear spacer on mainshaft, flat side up, engaging splines of gear with splines of spacer.
22. Install the third-speed gear washer on mainshaft, flat side towards spacer.
23. Align slot in ID of washer with keyway in shaft and move the key upwards to engage the third-speed gear washer.
24. Install the third-fourth speed sliding clutch gear, aligning large slot in clutch gear with keyway in shaft (Fig. 12).
25. Remove the assembly from vise and move the long key until the snap ring groove in key aligns with the 2nd snap ring groove from end in mainshaft.
26. Install the reverse gear, snap ring groove to the rear, on rear of mainshaft and move as far forward as possible into engagement with sliding clutch gear.
27. Install the reverse gear spacer over end of mainshaft, flat side against washer.
28. Install the front mainshaft coupling snap ring on mainshaft and key, securing key to mainshaft at 2nd snap ring groove from end in mainshaft.

DRIVE GEAR

Disassembly

1. Relieve the drive gear bearing nut at points where it is peened into milled slots of shaft (Fig. 13).
2. Turn the drive gear bearing nut from shaft, **left-hand thread.**
3. Using the rear face of the drive gear as a base, mount the assembly in a press, and press the shaft through the gear to unseat bearing, spacer and drive gear from shaft.
4. If necessary, remove the snap ring from ID of drive gear.

Assembly

1. Install snap ring in groove in ID of drive gear.
2. Install the drive gear on shaft, engaging internal splines of gear with teeth on shaft, snap ring of gear towards the front.
3. Install the drive gear spacer on shaft and against snap ring.
4. Press the drive gear bearing on shaft, shield to the front.
5. Apply Loctite to threads of shaft and nut.
6. Install the bearing nut on shaft, lefthand thread, with 250-300 ft-lbs. of torque. Wipe off excess Loctite.
7. Peen the nut into the two milled slots of shaft. To hasten the hardening of Loctite, place the assembly under heat lamps 10 to 15 minutes.

COUNTERSHAFTS

Disassembly

Both countershafts are identical, except for the number of teeth on the PTO gears; thus they are disassembled in the same manner.

1. Press the second, third, PTO and fourth-speed gears from countershaft. This will require a press of at least 25-ton capacity. Use metal shield on press as safety precaution (Fig. 14). The reverse speed gear and the low-low gear are integral with countershaft.
2. Press the first speed gear from countershaft.
3. Remove the long key from countershaft if necessary.
4. Remove the Woodruff key from countershaft if necessary.
5. Remove pin from countershaft if necessary.

Assembly

Except for the number of teeth on the power take-off gears, the countershafts are identical and assembled in the same manner.

1. Install the Woodruff key in countershaft (Fig. 15).
2. If previously removed, install pin in bore in keyway of countershaft.
3. Install the key in countershaft.
4. Press the first speed gear on countershaft, long hub to the front (Fig. 16).
5. Align keyway in gear with keys in shaft and press the second-speed gear on countershaft, long hub to the rear (Fig. 17).
6. Press the third-speed gear on countershaft, long hub to the front (Fig. 18).
7. Press the power take-off gear on countershaft, bullet end of teeth to the rear (Fig. 19).
8. Press the fourth-speed gear (drive gear) on countershaft, long hub of gear to the rear (Fig. 20).
9. The left countershaft takes a 47tooth PTO gear, the right a 45-tooth PTO gear. After completing assembly of countershafts, mark assemblies wither left or right to correspond with PTO gear.

SHIFTING BAR HOUSING

Disassembly

Lay all parts on a clean bench in the order in which they are removed to facilitate reassembly. **Bars not being removed from housing must be kept in a neutral position or interlock parts will lock bars.**

1. Tilt housing and remove the tension springs and balls from bores in top of housing (Fig. 21).
2. Set the housing in a vise with the plunger side up.
3. Starting with the upper bar, move all bars to the rear and out of housing as detailed in the following instructions. Cut lock wire and remove lock screws from each bar just prior to its removal.
4. Move the upper shifting bar to the rear and from housing, removing the shift block and the shift yoke from bar.
5. Move the center bar to the rear and from housing, removing the shift block and the shift yoke from bar. As neutral notch in the shift bar clears the housing boss, remove the interlock pin from bore in neutral notch.
6. Remove the actuating plunger from bore in housing.
7. Move the lower bar to the rear and out of housing, removing the shift yoke from bar.
8. Two interlock balls will fall from interlock ball opening in rear boss of housing as last bar is removed.

Assembly

1. Install the housing in a vise with the short bar location at the bottom, rear of housing to the right.

Shifting bars are to be installed through the rear bores of housing with neutral and shift notches to the rear. Keep bars in the neutral position when installed.

2. Install the short low low-reverse shifting bar into housing in the lowest bore, installing the shifting yoke on bar.

If previously disassembled, install reverse stop plunger, spring and plug in bore until 1 1/2 to 2 threads protrude. Make sure plunger can fully depress into bore at yoke slot. Stake plug through small hole in yoke.

3. Install the yoke lock screw, tighten and wire securely.
4. Install the actuating plunger in bore in left side of housing, flat end outward.
5. Install 3/4 inch interlock ball in bore in rear boss. This ball rides between the low low-reverse shifting bar and the first-second speed shifting bar.
6. Install the first-second speed shifting bar through the center bore in housing, through the shifting block, the center boss and the shift yoke. Block is installed with the wire support to the rear; yoke is installed with fork to the rear. Install interlock pin in bore in neutral notch of bar as neutral notch enters rear boss in housing.

Keep bar so that interlock pin remains in a vertical position during the remainder of the assembly. Rotation of bar will allow interlock pin to jam into tension spring bores.

7. Install the block and yoke lock screws, tighten and wire securely.
8. Install the 3/4 inch interlock ball in bore in rear boss. This ball rides between the first-second speed shifting bar and the third-fourth speed shifting bar.
9. Install the third-fourth speed shifting bar in top bore of housing, through the shifting block, the center boss and the third-fourth speed shifting yoke, fork to the front.
10. Install the block and yoke lock screws, tighten and wire securely.
11. Remove shifting bar assembly from vise and place on work bench.
12. Install the three tension balls in bores in top of housing.
13. Install the three tension springs in bores in top of housing. The black spring is installed in the left bore (third-fourth shift bar). Red springs are installed in the other two bores.

AUXILIARY TRANSMISSION

SEPARATION OF MAIN AND AUXILIARY SECTIONS

1. With the transmission assembly removed from vehicle and air lines disconnected, turn out the capscrews which attach the auxiliary housing to the transmission case.
2. Install three puller screws in the tapped holes in housing and tighten evenly to move the auxiliary section to the rear to break gasket seal.
3. Attach chain hoist to housing to properly balance and to relieve the weight of the auxiliary section (Fig. 22).
4. Continue to move the auxiliary section to the rear until free of transmission. This assembly consists of the housing, the auxiliary countershafts, low speed gear, output shaft, shift cylinder and synchronizer assemblies, range mainshaft, splitter gear and sliding clutch. There is nothing to restrict the movement of the auxiliary except the two dowel pins in the rear flange of the case.

Transmission can also be set vertically to remove the auxiliary section. Block under clutch housing to prevent damage to drive gear shaft and lift the auxiliary upward and from transmission case.

JOINING OF MAIN AND AUXILIARY SECTIONS

1. Make sure the two dowel pins are in place in rear face of transmission. These are installed with the long taper protruding to the rear and the front of the pin flush with the front face of flange.
2. Place a chain hoist on auxiliary assembly to properly balance and hold its weight.
3. Move the auxiliary section evenly onto rear of transmission. the two countershaft drive gears will mesh with the auxiliary drive gear and front of countershafts will seat in the two bearings installed in front section. Move assembly evenly, rotating drive gear if necessary, to properly mesh gears.

Auxiliary section can also be installed by setting front section vertically on wood blocks and by lowering the auxiliary evenly on transmission.

4. Install the attaching capscrews and tighten securely.
5. Connect air lines and install transmission assembly in vehicle.

AUXILIARY SECTION

Disassembly

1. Remove the shift cylinder cover bolts and remove the cover.
2. Remove the nut from the end of the shifter shaft. Using air on low range port, remove the piston from the shift cylinder. **Do not stand in back of piston.**
3. Remove the bolts that attach the shift cylinder housing to the rear plate.
4. Cut the lock wires and remove the set screws from the shifting fork. If necessary, rotate the shift cylinder housing to expose the set screws (Fig. 23).
5. Push the shifter shaft to the inside, through the fork hub and out of the cylinder housing. Remove the shifting fork and shift cylinder housing from the plate.
6. If necessary, remove the O-rings from the piston and shift cylinder housing (Fig. 24).
7. To remove the countershaft assemblies, place the rear plate on wood blocks so that the front of the countershafts are approximately two inches from the work bench. Also, **place blocking under the synchronizer assembly to prevent it from moving.**

If the synchronizer moves downward and off the mainshaft, the springs will be forcibly ejected from the synchronizer.

8. Remove the bolts that attach the countershaft rear bearing covers to the plate. Remove the covers.
9. Remove snap rings from rear of each countershaft.
10. Using a hammer and a soft drift, tap the rear of the countershafts to unseat them from the bearings.
11. Use puller to remove bearings from shafts and bores.
12. Pull the synchronizer assembly from the output shaft as a complete unit.
13. Pull the direct (high range) cone synchronizer ring from pins of the low-speed synchronizer ring, covering with cloth to catch the blocker spring installed in bores of the direct cone synchronizer. Lay large low-speed ring on table and pull direct cone slowly upward.
14. Remove sliding clutch gear from pins of low-speed synchronizer.
15. Remove the key from keyway between splines of range mainshaft.
16. Turn splines of low-speed gear washer, located in hub of gear, to align with splines of shaft.
17. Remove the low-speed gear and splined washer from shaft.
18. Remove the clutching collar from shaft.
19. Remove the right countershaft from auxiliary housing.
20. Turn out capscrews and remove the splitter gear shift cylinder cover.
21. Cut lock wire and turn out lock screw from shifting yoke.
22. Pull shifting bar and piston out through rear of shift cylinder.
23. Remove O-ring from OD of piston if necessary.
24. Remove O-ring from small diameter at end of shifting bar if necessary.
25. Remove the shifting yoke from sliding clutch gear and withdraw the shift cylinder from housing.
26. Remove the left countershaft assembly.
27. With soft bar and maul, or with use of press, move the splitter gear and output shaft assembly forward and out of rear bearing.
28. Remove the bearing inner spacer from shaft.
29. Using the front face of the splitter gear as a base, press the tailshaft through the gear and front cone of bearing, freeing gear, washer and bearing cone (Fig. 25).
30. Remove splined thrust washer from gear and, if necessary, remove snap ring from gear.
31. Remove snap ring from front of quill.
32. Pull the range mainshaft from quill using the sliding clutch as a base for puller jaws. This will free range mainshaft and sliding clutch.
33. Remove the ball bearing and needle bearing from range mainshaft if necessary.
34. Remove snap ring from range mainshaft if necessary.
35. Turn out the attaching capscrews and the nut from stud on rear bearing cover.
36. Tap lightly to break gasket seal, and remove the rear bearing cover.
37. Remove oil seal from cover.
38. Remove the bearing rear cone from housing.
39. Push parts to the rear to remove the two cups and outer spacer of bearing from housing bore.

The auxiliary countershafts, drive gear and over-drive gear are one piece and cannot be disassembled. The two gears are welded to the shaft at the time of manufacture.

40. If necessary, remove bearing inner race from front of countershaft.

Assembly

For timing purposes, mark the tooth on each over-drive gear which is stamped with an O. Install inner race of bearing on front of countershafts.

The quill should not be removed from output shaft unless replacement of quill is necessary. If replaced, press quill into output shaft until shoulder seats squarely against shaft. Check shaft on centers; shaft should not be over .003 inch.

1. Install splitter gear sliding clutch on splines of output shaft, internal splines to the rear.
2. If previously removed, install the bushing in the range mainshaft 1/16 inch below face.
3. Install the snap ring in groove at end of splines in range mainshaft.
4. Install the range mainshaft on quill of output shaft.
5. Install the front ball bearing in range mainshaft and on quill. Seat with sleeve driver slightly larger than ID of bearing inner race.
6. Install snap ring in groove on front of quill.
7. Install snap ring in groove of splitter (over-drive) gear.
8. Mark any two adjacent gear teeth on the splitter gear. Then mark the two adjacent teeth which are directly opposite the first set marked (Fig. 26).
9. Install the splined washer on shaft and against shaft shoulder.
10. Install the splitter gear on splined washer, clutching teeth to the front.
11. Install the rear washer on output shaft, flat side to the rear.
12. Install the front cone of Timken bearing on shaft and against washer, taper towards the thread end. This is a matched bearing; make sure the correct cone and cup are matched. **Heating of bearing cones to install on output shaft is recommended, provided the bearing is not heated over 275 degrees F. Heat lamps are recommended for heating purposes.**
13. Install the bearing inner spacer on shaft and against the bearing cone.
14. Start the front cup of bearing into rear of bore in auxiliary housing, taper to the inside.
15. Place the bearing outer spacer on cup and place the rear cup of bearing on spacer, lip to the rear.
16. Tap the two cups and spacer lightly and evenly to seat in rear bore, seating lip on rear cup against housing.
17. Place the rear plate with assembled cups over output shaft.
18. Install heated bearing rear cone on shaft and into rear cup.
19. Install oil seal in rear bearing cover if previously removed. **Check rear bearing cover for speedometer bushing.**
20. Install the rear bearing cover on

center bore. Tighten capscrews securely. **Make sure that output shaft is to the rear as far as possible.**

21. Place the left countershaft into position, meshing marked timing tooth on over-drive gear with two marked teeth on the splitter gear. **Do not install rear bearing.**
22. Install O-ring in splitter cylinder shift bore.
23. Place the shift yoke fork in position in sliding clutch gear. Install the splitter shift cylinder into rear bore and place hub of shift yoke into position in cylinder with long hub to the front.
24. Install O-ring on OD of piston.
25. Install the shift bar from the rear into shift cylinder and through the yoke hub.
26. Install lock screw in yoke hub and secure with safety wire.
27. Install splitter insert valve in cover.
28. Install exhaust screw in cover to secure insert valve.
29. Install the splitter shift cylinder cover with the exhaust screw down and supply port to the right, tighten capscrews securely.
30. Place the right countershaft into position, meshing marked tooth on over-drive gear with two marked teeth on the splitter gear. **Do not install rear bearing.**
31. Install the splitter gear clutching collar on splines of range mainshaft against snap ring, clutching teeth to the rear.
32. Install the low range gear on range mainshaft and against clutching collar.
33. Install the splined washer on range mainshaft and into hub of low range gear. Align splines of washer with raised splines of shaft.
34. Lock the low range gear into position by inserting the range mainshaft key between splines of shaft and washer.
35. Place the larger low-speed synchronizer ring on work bench with pins upwards.
36. Install the sliding clutch gear on pins of the low-speed synchronizer, protruding clutching teeth down.
37. Install the three springs in bores in the direct synchronizer ring (Fig. 27).
38. Place the direct synchronizer ring over pins of the low range synchronizer ring, seating springs against pins.
39. Apply pressure to direct synchronizer ring so as to compress springs and seat pins of low-speed synchronizer fully into bores of direct synchronizer plate.

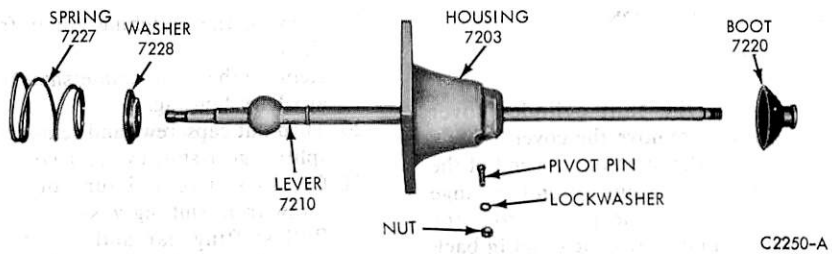

FIG. 5 Gear Shift Lever and Housing—Disassembled

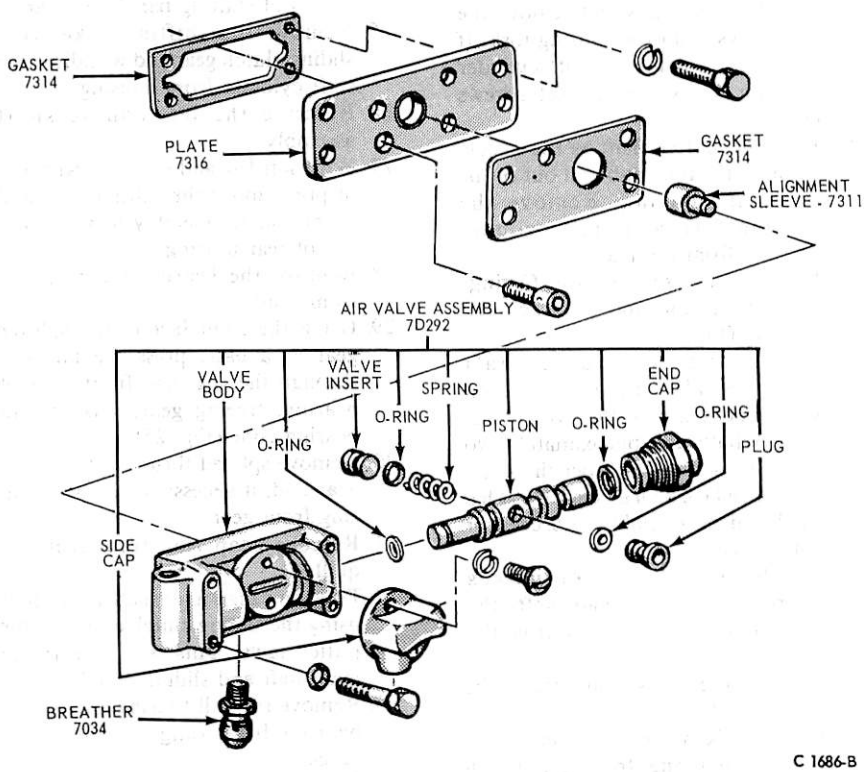

FIG. 6 Air Valve Disassembled

40. Spread the countershaft assemblies and place the assembled synchronizer assembly on the range mainshaft, fitting low range cone into mating cone on low range gear.
41. Set housing with front end of countershafts on bench. Center rear of countershafts in housing bores.

Make sure that marked timing teeth on countershaft over-drive gear are meshed with the marked timing teeth on splitter gear (Fig. 28).

42. Install rear bearings on shafts and into bores.
43. Install snap ring on rear of each countershaft.
44. Install rear bearing covers, tighten capscrews securely.
45. Install O-ring in bore of shift cylinder.
46. Install washer in bore of shift cylinder and against O-ring.
47. Install snap ring in bore of shift cylinder to secure washer.
48. Place the range shifting yoke into yoke slot of sliding clutch gear, long hub to the rear.
49. Install the shift cylinder through rear plate bore and place the hub of shifting yoke into position in shift cylinder housing (Fig. 29).
50. Insert thread end of shifting bar into shift cylinder from the front, through the yoke hub and into cylinder.
51. Align lock screw holes in yoke hub with slots in shifting bar and install yoke lock screws.
52. Install capscrews in shift cylinder and tighten securely.

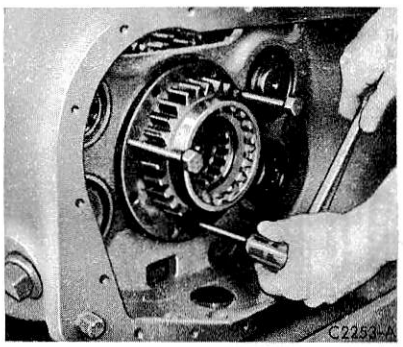

FIG. 7 Pulling Auxiliary Drive Gear Assembly from Case Bore

53. Install O-ring in ID of shifting bar piston.
54. Install O-ring on OD of piston.
55. Install piston into cylinder bore and on shifting bar, flat side outward.
56. Install the elastic stop nut on shifting bar, tighten securely.
57. If previously removed, install air line fitting in air cylinder port, 90 degrees ell facing toward center of transmission.
58. Install cover on shift cylinder, air port towards upper left.
59. If previously removed, install air line fitting in cover air cylinder port, 90 degrees ell facing toward center of transmission.

If a gasket is used which requires shellac or permatex, use only a very small amount to prevent clogging of cylinder air ports or damage to O-rings.

DESCRIPTION

TRANSMISSION

The Spicer model P8516 is an air-shifted compound transmission (Fig. 1).

One shift lever controls the selection of all sixteen forward speeds and four reverse speeds. The four-speed main section is shifted by manually moving the shift lever while the auxiliary portion is air-shifted by a flip switch button on the shift lever. Model P8516-3A has a 12.26 to one low-low gear ratio which makes it suitable for either on-or-off highway use. Model P8516-B has a 10.45:1 low-low ratio making it more suitable for on-highway operation.

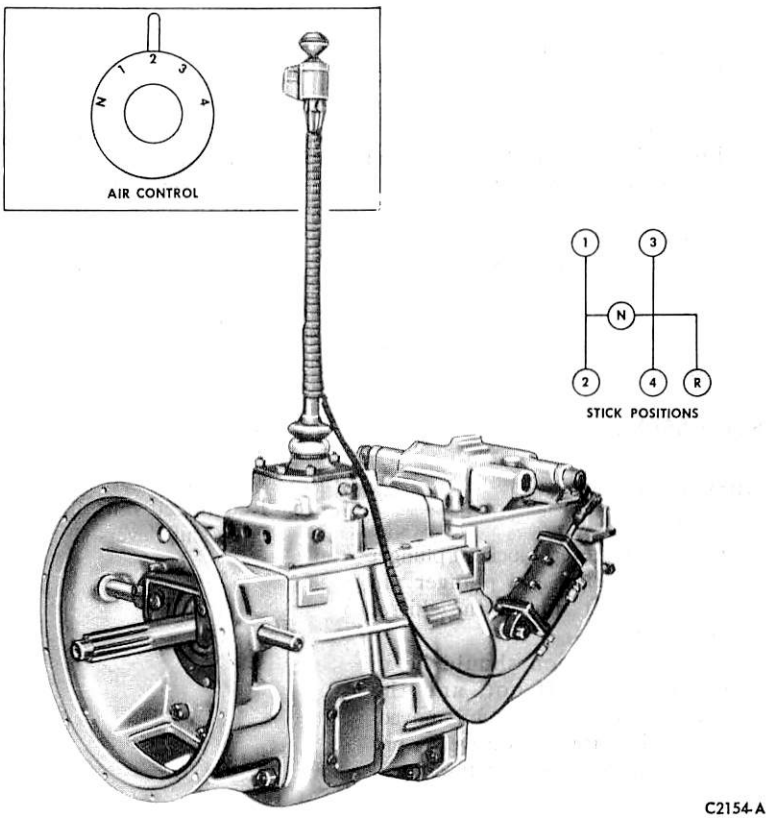

FIG. 1 P8516 Sixteen-Speed Compound Transmission

REMOVAL AND INSTALLATION

FRONT UNIT OVERHEAD CONTROL ASSEMBLY (GEAR SHIFT LEVER)

Removal

1. Shift the transmission into reverse.
2. Remove the retaining capscrews and washers (Fig. 2).
3. Separate the shifter dome from the filler block (if so equipped) or shifter housing and gasket(s) and lift straight up.

Installation

1. Shift unit into neutral so notches of shift forks and brackets align.
2. **Use light coat of gasket cement to assemble new gasket to shifter housing opening. If filler block is used, a second gasket will have to be used as shown in Fig. 2.**
3. Place shift lever and dome assembly on shifter housing, noting that finger end of shift lever enters the neutral positioned notches.
4. Secure with six capscrews and lock washers.
5. Assemble reverse lockout plunger to shifter housing. Preload and secure with spring in retainer.
6. Check shifting of transmission into all gear positions for satisfactory operation.

TRANSMISSION

Removal

1. Bleed the air reservoirs. Disconnect the air line at the top right side of the transmission.
2. Disconnect the drive shaft at the parking brake drum, and disconnect the speedometer cable (if so equipped).
3. After cleaning the area around the cross-shaft housing, remove the housing and tie it out of the way. Cover the opening in the gear shift housing.
4. Remove the shift control cable retaining clamp, and disconnect the cable at the air shift valve. Remove the two clevis pins securing the air shift cylinder (necessary for clearance of the transmission jack).
5. Disconnect the clutch release lever retracting spring. Remove the slave cylinder mounting bolts, and position the slave cylinder out of the way.
6. Remove all but two upper bolts of the clutch housing attaching bolts at the engine.
7. After securing a transmission jack to the transmission (Tool LRE 1790), raise the transmission slightly to relieve pressure at the side rail mounting brackets. Disconnect the mounting brackets (Fig. 3).
8. Disconnect the parking brake rod clevis and both air line clamps (on the side rail brackets). Disconnect the back-up light wire.
9. After removing the remaining clutch housing retaining bolts, pull the transmission rearward to clear the

input shaft.

10. Raise the front of the truck enough to provide clearance in removing the transmission, install safety stands, and then remove the transmission from under the vehicle.

Installation

1. Install two pilot studs in the clutch housing and remove the clutch housing dust cover.
2. Position the transmission under the vehicle, and then lower the vehicle.
3. Position the input shaft in the clutch discs, and start two of the transmission retaining bolts.
4. Torque all transmission-to-clutch-housing bolts to specification.
5. Install the air line retaining brackets on the side rail brackets. Connect the back-up light wire.
6. Install the clutch housing dust cover, the slave cylinder, and the retracting spring.
7. With the transmission front end connected at the engine and the transmission jack removed, position the transmission rear mounting studs and related parts (Fig. 3).
8. Torque the upper retaining nuts to specification. (Fig. 3).

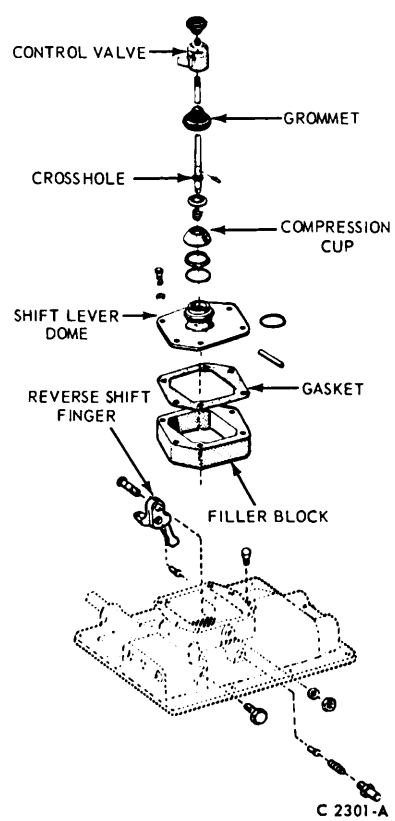

FIG. 2 Front Unit Overhead Control Assembly

9. Refer to Fig. 3 for further assembly instructions and Torque Valves.
10. Install the air shift cylinder, connect the air shift cable, and install the cable clamp.
11. Install the cross-shaft housing, and torque the mounting bolts to specification.
12. Connect the speedometer cable (if so equipped), the brake rod, and the air line.
13. Start the engine to build up air pressure, connect the drive shaft, and check for air leaks.

SUB-ASSEMBLIES

SHIFTER HOUSING

Removal

1. Remove the reverse lockout plunger retainer, spring and plunger pin from the left side of the shifter housing (Fig. 4).
2. The transmission should be in reverse gear. If not, and the overhead control has been removed, shift with a large screwdriver or pry bar, so that the reverse shift fork will clear.
3. Remove the retaining capscrews and lock washers. Lift the shifter housing straight up from the transmission case and gasket.

Installation

1. Use light coat of gasket cement and apply shift cover gasket to transmission case.
2. Place first-second and third-fourth speed sliding clutch gear collars in neutral position.
3. Slide reverse idler gear forward into complete engagement with countershaft gear.
4. Check to determine that shifter housing is in reverse and place housing in position on case. Make sure all three shift forks are in place on their respective shift collars.
5. Secure shifter housing to main case with capscrews and lock washers.
6. Before installing shift lever and dome, use large screwdriver or small pry bar and check movement of each shift rod to make sure transmission will shift easily and completely into each gear position.

AUXILIARY TRANSMISSION SUB-ASSEMBLIES

SHIFTER HOUSING

Removal

1. Remove the retaining capscrews and retaining stud nuts and lock washers.
2. Lift the housing straight up from the case and gasket.

Installation

1. Use light coat of gasket cement and assemble shifter housing gasket to rear case.
2. Place the front and rear sliding clutch gear collars in neutral position.
3. Check to determine that shift forks are in neutral position.
4. Place shifter housing into position on case, being careful that both shift forks engage their corresponding shift collars.
5. Secure shifter housing to rear case with capscrews, stud nuts and lock washers.
6. Reconnect shift linkage to outer cross shift levers (Fig. 4).
